Preface

This guide contains reference information, with usage and syntax guidelines, for:

- Oracle GoldenGate GGSCI commands.
- Oracle GoldenGate configuration parameters.
- Oracle GoldenGate column-conversion functions.
- Oracle GoldenGate user exit functions.

Audience

This guide is intended for the person or persons who are responsible for operating Oracle GoldenGate and maintaining its performance. This audience typically includes, but is not limited to, systems administrators and database administrators.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Related Documents

The Oracle GoldenGate documentation set includes the following components:

Windows, UNIX, and Linux Platforms

- Installing and Configuring Oracle GoldenGate for DB2 for i
- Installing and Configuring Oracle GoldenGate for DB2 LUW
- Installing and Configuring Oracle GoldenGate for DB2 z/OS
- Installing and Configuring Oracle GoldenGate for Informix
- Installing and Configuring Oracle GoldenGate for MySQL
- Installing and Configuring Oracle GoldenGate for NonStop SQL/MX
Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, such as &quot;From the File menu, select Save.&quot; Boldface also is used for terms defined in text or in the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates placeholder variables for which you supply particular values, such as in the parameter statement: <code>TABLE table_name</code>. Italic type also is used for book titles and emphasis.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates code components such as user exits and scripts; the names of files and database objects; URL paths; and input and output text that appears on the screen. Uppercase monospace type is generally used to represent the names of Oracle GoldenGate parameters, commands, and user-configurable functions, as well as SQL commands and keywords.</td>
</tr>
<tr>
<td><strong>UPPERCASE</strong></td>
<td>Uppercase in the regular text font indicates the name of a utility unless the name is intended to be a specific case.</td>
</tr>
<tr>
<td><code>{}</code></td>
<td>Braces within syntax enclose a set of options that are separated by pipe symbols, one of which must be selected, for example: `(option1</td>
</tr>
<tr>
<td><code>[]</code></td>
<td>Brackets within syntax indicate an optional element. For example in this syntax, the <strong>SAVE</strong> clause is optional: <code>CLEANUP REPLICA? group_name [], SAVE count</code>. Multiple options within an optional element are separated by a pipe symbol, for example: `(option1</td>
</tr>
</tbody>
</table>
Oracle GoldenGate GGSCI Commands

This chapter describes the commands that can be issued through the Oracle GoldenGate Software Command Interface (GGSCI). This is the command interface between users and Oracle GoldenGate functional components.

1.1 Summary of Oracle GoldenGate Commands

This section summarizes the GGSCI commands and includes the following topics:

- Section 1.1.1, "Summary of Manager Commands"
- Section 1.1.2, "Summary of Extract Commands"
- Section 1.1.3, "Summary of Replicat Commands"
- Section 1.1.4, "Summary of the ER Command"
- Section 1.1.5, "Summary of Wallet Commands"
- Section 1.1.6, "Summary of Credential Store Commands"
- Section 1.1.7, "Summary of Trail Commands"
- Section 1.1.8, "Summary of Parameter Commands"
- Section 1.1.9, "Summary of Database Commands"
- Section 1.1.10, "Summary of Trandata Commands"
- Section 1.1.11, "Summary of Checkpoint Table Commands"
- Section 1.1.12, "Summary of Oracle Trace Table Commands"
- Section 1.1.13, "Summary of Oracle GoldenGate Data Store Commands"
- Section 1.1.14, "Summary of Oracle GoldenGate Monitor JAgent Commands"
- Section 1.1.15, "Summary of Miscellaneous Oracle GoldenGate Commands"

1.1.1 Summary of Manager Commands

Use the Manager commands to control the Manager process. Manager is the parent process of Oracle GoldenGate and is responsible for the management of its processes and files, resources, user interface, and the reporting of thresholds and errors.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFO MANAGER</td>
<td>Returns information about the Manager port and child processes.</td>
</tr>
</tbody>
</table>
1.1.2 Summary of Extract Commands

Use the Extract commands to create and manage Extract groups. The Extract process captures either full data records or transactional data changes, depending on configuration parameters, and then sends the data to a trail for further processing by a downstream process, such as a data-pump Extract or the Replicat process.

Table 1–2  Extract Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD EXTRACT</td>
<td>Creates an Extract group.</td>
</tr>
<tr>
<td>ALTER EXTRACT</td>
<td>Changes attributes of an Extract group</td>
</tr>
<tr>
<td>CLEANUP EXTRACT</td>
<td>Deletes run history for an Extract group</td>
</tr>
<tr>
<td>DELETE EXTRACT</td>
<td>Deletes an Extract group.</td>
</tr>
<tr>
<td>INFO EXTRACT</td>
<td>Returns information about an Extract group</td>
</tr>
<tr>
<td>KILL EXTRACT</td>
<td>Forcibly terminates the run of an Extract group</td>
</tr>
<tr>
<td>LAG EXTRACT</td>
<td>Returns information about Extract lag</td>
</tr>
<tr>
<td>REGISTER EXTRACT</td>
<td>Registers an Extract group with an Oracle database.</td>
</tr>
<tr>
<td>SEND EXTRACT</td>
<td>Sends instructions to, or returns information about,</td>
</tr>
<tr>
<td></td>
<td>a running Extract group.</td>
</tr>
<tr>
<td>START EXTRACT</td>
<td>Starts an Extract group.</td>
</tr>
<tr>
<td>STATS EXTRACT</td>
<td>Returns processing statistics for an Extract group.</td>
</tr>
<tr>
<td>STATUS EXTRACT</td>
<td>Returns the state of an Extract group.</td>
</tr>
<tr>
<td>STOP EXTRACT</td>
<td>Stops an Extract group.</td>
</tr>
<tr>
<td>UNREGISTER EXTRACT</td>
<td>Unregisters an Extract group from an Oracle database.</td>
</tr>
</tbody>
</table>

1.1.3 Summary of Replicat Commands

Use the Replicat commands to create and manage Replicat groups. The Replicat process reads data extracted by the Extract process and applies it to target tables or prepares it for use by another application, such as a load application.

Table 1–3  Replicat Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD REPLICAT</td>
<td>Adds a Replicat group.</td>
</tr>
<tr>
<td>ALTER REPLICAT</td>
<td>Changes attributes of a Replicat group.</td>
</tr>
<tr>
<td>CLEANUP REPLICAT</td>
<td>Deletes run history of a Replicat group.</td>
</tr>
<tr>
<td>DELETE REPLICAT</td>
<td>Deletes a Replicat group.</td>
</tr>
</tbody>
</table>
### 1.1.4 Summary of the ER Command

Use the ER command to issue standard Extract and Replicat commands to multiple Extract and Replicat groups as a unit. See "ER" on page 1-89 for how to use this command.

#### Table 1–4  ER Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INFO REPLICAT *</td>
<td>Returns information about the specified wildcarded groups.</td>
</tr>
<tr>
<td>KILL REPLICAT *</td>
<td>Forcibly terminates the specified wildcarded groups.</td>
</tr>
<tr>
<td>LAG REPLICAT *</td>
<td>Returns lag information about the specified wildcarded groups.</td>
</tr>
<tr>
<td>SEND REPLICAT *</td>
<td>Sends instructions to, or returns information about, the specified wildcarded groups.</td>
</tr>
<tr>
<td>START REPLICAT *</td>
<td>Starts the specified wildcarded groups.</td>
</tr>
<tr>
<td>STATS REPLICAT *</td>
<td>Returns processing statistics for the specified wildcarded groups.</td>
</tr>
<tr>
<td>STATUS REPLICAT *</td>
<td>Returns the state of the specified wildcarded groups.</td>
</tr>
<tr>
<td>STOP REPLICAT *</td>
<td>Stops the specified wildcarded groups.</td>
</tr>
</tbody>
</table>

### 1.1.5 Summary of Wallet Commands

Use the wallet commands to manage the master-key wallet that stores Oracle GoldenGate master encryptions keys, and to add master keys to this wallet.

#### Table 1–5  Wallet Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE WALLET</td>
<td>Creates a wallet that stores master encryption keys.</td>
</tr>
<tr>
<td>OPEN WALLET</td>
<td>Opens a master-key wallet.</td>
</tr>
</tbody>
</table>
1.1.6 Summary of Credential Store Commands

Use the credential store commands to manage an Oracle GoldenGate credential store and to add credentials to the credential store.

Table 1–6  Credential Store Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD CREDENTIALSTORE</td>
<td>Creates a credentials store (wallet) that stores encrypted database user credentials.</td>
</tr>
<tr>
<td>ALTER CREDENTIALSTORE</td>
<td>Changes the contents of a credentials store.</td>
</tr>
<tr>
<td>INFO CREDENTIALSTORE</td>
<td>Returns information about a credentials store.</td>
</tr>
<tr>
<td>DELETE CREDENTIALSTORE</td>
<td>Deletes the wallet that serves as a credentials store.</td>
</tr>
</tbody>
</table>

1.1.7 Summary of Trail Commands

Use the trail commands to create and manage Oracle GoldenGate trails. A trail is a series of files in which Oracle GoldenGate temporarily stores extracted data on disk until it has been applied to the target location.

Table 1–7  Trail Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD EXTRAIL</td>
<td>Adds a local trail to the Oracle GoldenGate configuration.</td>
</tr>
<tr>
<td>ADD RMTTRAIL</td>
<td>Adds a remote trail to the Oracle GoldenGate configuration.</td>
</tr>
<tr>
<td>ALTER EXTRAIL</td>
<td>Changes attributes of a local trail.</td>
</tr>
<tr>
<td>ALTER RMTTRAIL</td>
<td>Changes attributes of a remote trail.</td>
</tr>
<tr>
<td>DELETE EXTRAIL</td>
<td>Removes a local trail from the Oracle GoldenGate configuration.</td>
</tr>
<tr>
<td>DELETE RMTTRAIL</td>
<td>Removes a remote trail from the Oracle GoldenGate configuration.</td>
</tr>
<tr>
<td>INFO EXTRAIL</td>
<td>Returns information about a local trail.</td>
</tr>
<tr>
<td>INFO RMTTRAIL</td>
<td>Returns information about a remote trail.</td>
</tr>
</tbody>
</table>

1.1.8 Summary of Parameter Commands

Use the parameter commands to view and manage Oracle GoldenGate parameter files. See *Administering Oracle GoldenGate for Windows and UNIX* for more information about how to work with parameter files.
**Table 1–8 Parameter Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EDIT PARAMS</td>
<td>Opens a parameter file for editing in the default text editor.</td>
</tr>
<tr>
<td>SET EDITOR</td>
<td>Sets the default text editor program for editing parameter files.</td>
</tr>
<tr>
<td>VIEW PARAMS</td>
<td>Displays the contents of a parameter file in read-only mode on-screen.</td>
</tr>
</tbody>
</table>

**1.1.9 Summary of Database Commands**

Use the database commands to interact with the database from GGSCI.

**Table 1–9 Database Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBLOGIN</td>
<td>Logs the GGSCI session into a database so that other commands that affect the database can be issued.</td>
</tr>
<tr>
<td>DUMPDDL</td>
<td>Shows the data in the Oracle GoldenGate DDL history table.</td>
</tr>
<tr>
<td>ENCRYPT PASSWORD</td>
<td>Encrypts a database login password.</td>
</tr>
<tr>
<td>FLUSH SEQUENCE</td>
<td>Updates an Oracle sequence so that initial redo records are available at the time that Extract starts capturing transaction data after the instantiation of the replication environment.</td>
</tr>
<tr>
<td>LIST TABLES</td>
<td>Lists the tables in the database with names that match the input specification.</td>
</tr>
<tr>
<td>MININGDBLOGIN</td>
<td>Specifies the credentials of the user that an Oracle GoldenGate process uses to log into an Oracle mining database.</td>
</tr>
<tr>
<td>SET NAMECCSID</td>
<td>Sets the CCSID of the GGSCI session in a DB2 for i environment.</td>
</tr>
</tbody>
</table>

**1.1.10 Summary of Trandata Commands**

Use trandata commands to configure the appropriate database components to provide the transaction information that Oracle GoldenGate needs to replicate source data operations.

**Table 1–10 Trandata Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD SCHEMATRANDATA</td>
<td>Enables schema-level supplemental logging.</td>
</tr>
<tr>
<td>ADD TRANDATA</td>
<td>Enables table-level supplemental logging.</td>
</tr>
<tr>
<td>DELETE SCHEMATRANDATA</td>
<td>Disables schema-level supplemental logging.</td>
</tr>
<tr>
<td>DELETE TRANDATA</td>
<td>Disables table-level supplemental logging.</td>
</tr>
<tr>
<td>INFO SCHEMATRANDATA</td>
<td>Returns information about the state of schema-level supplemental logging.</td>
</tr>
<tr>
<td>INFO TRANDATA</td>
<td>Returns information about the state of table-level supplemental logging.</td>
</tr>
</tbody>
</table>

**1.1.11 Summary of Checkpoint Table Commands**

Use the checkpoint table commands to manage the checkpoint table that is used by Oracle GoldenGate to track the current position of Replicat in the trail.
For more information about checkpoints and using a checkpoint table, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Table 1–11  Checkpoint Table Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD CHECKPOINTTABLE</td>
<td>Creates a checkpoint table in a database.</td>
</tr>
<tr>
<td>CLEANUP CHECKPOINTTABLE</td>
<td>Removes checkpoint records that are no longer needed.</td>
</tr>
<tr>
<td>DELETE CHECKPOINTTABLE</td>
<td>Removes a checkpoint table from a database.</td>
</tr>
<tr>
<td>INFO CHECKPOINTTABLE</td>
<td>Returns information about a checkpoint table.</td>
</tr>
<tr>
<td>UPGRADE CHECKPOINTTABLE</td>
<td>Adds a supplemental checkpoint table when upgrading Oracle GoldenGate from version 11.2.1.0.0 or earlier.</td>
</tr>
</tbody>
</table>

**1.1.12 Summary of Oracle Trace Table Commands**

Use the trace table commands to manage the Oracle GoldenGate trace table that is used with bidirectional synchronization of Oracle databases. Replicat generates an operation in the trace table at the start of each transaction. Extract ignores all transactions that begin with an operation to the trace table. Ignoring Replicat's operations prevents data from looping back and forth between the source and target tables.

For more information about bidirectional synchronization, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Table 1–12  Oracle Trace Table Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD TRACETABLE</td>
<td>Creates a trace table.</td>
</tr>
<tr>
<td>DELETE TRACETABLE</td>
<td>Removes a trace table.</td>
</tr>
<tr>
<td>INFO TRACETABLE</td>
<td>Returns information about a trace table.</td>
</tr>
</tbody>
</table>

**1.1.13 Summary of Oracle GoldenGate Data Store Commands**

Use the data store commands to control the data store that Oracle GoldenGate uses to store monitoring information for use by Oracle GoldenGate Monitor.

**Table 1–13  Oracle GoldenGate Veridata Data Store Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER DATASTORE</td>
<td>Changes the memory model that is used for interprocess communication by the data store.</td>
</tr>
<tr>
<td>CREATE DATASTORE</td>
<td>Creates the data store.</td>
</tr>
<tr>
<td>DELETE DATASTORE</td>
<td>Removes the data store.</td>
</tr>
<tr>
<td>INFO DATASTORE</td>
<td>Returns information about the data store.</td>
</tr>
<tr>
<td>REPAIR DATASTORE</td>
<td>Repairs the data store after an upgrade or if it is corrupt.</td>
</tr>
</tbody>
</table>

**1.1.14 Summary of Oracle GoldenGate Monitor JAgent Commands**

Use the JAgent commands to control the Oracle GoldenGate Monitor JAgent.
### 1.1.15 Summary of Miscellaneous Oracle GoldenGate Commands

Use the following commands to control various other aspects of Oracle GoldenGate.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>!</td>
<td>Executes a previous GGSCI command without modifications.</td>
</tr>
<tr>
<td>ALLOWNESTED</td>
<td>Enables or disables the use of nested OBEY files.</td>
</tr>
<tr>
<td>NOALLOWNESTED</td>
<td></td>
</tr>
<tr>
<td>CREATE SUBDIRS</td>
<td>Creates the default directories within the Oracle GoldenGate home directory.</td>
</tr>
<tr>
<td>DEFAULTJOURNAL</td>
<td>Sets a default journal for multiple tables or files for the ADD TRANDATA command when used for a DB2 for i database.</td>
</tr>
<tr>
<td>FC</td>
<td>Allows the modification and re-execution of a previously issued GGSCI command.</td>
</tr>
<tr>
<td>HELP</td>
<td>Provides assistance with syntax and usage of GGSCI commands.</td>
</tr>
<tr>
<td>HISTORY</td>
<td>Shows a list of the most recently issued commands since the startup of the GGSCI session.</td>
</tr>
<tr>
<td>INFO ALL</td>
<td>Displays status and lag for all Oracle GoldenGate processes on a system.</td>
</tr>
<tr>
<td>INFO MARKER</td>
<td>Displays recently processed markers from a NonStop system.</td>
</tr>
<tr>
<td>OBEY</td>
<td>Processes a file that contains a list of Oracle GoldenGate commands.</td>
</tr>
<tr>
<td>SHELL</td>
<td>Executes shell commands from within the GGSCI interface.</td>
</tr>
<tr>
<td>SHOW</td>
<td>Displays the attributes of the Oracle GoldenGate environment.</td>
</tr>
<tr>
<td>VERSIONS</td>
<td>Displays information about the operating system and database.</td>
</tr>
<tr>
<td>VIEW GGSEVT</td>
<td>Displays the Oracle GoldenGate error log (ggserr.log file).</td>
</tr>
<tr>
<td>VIEW REPORT</td>
<td>Displays the process report or the discard file that is generated by Extract or Replicat.</td>
</tr>
</tbody>
</table>
INFO MANAGER

Use INFO MANAGER (or INFO MGR) to determine whether or not the Manager process is running and the process ID. If Manager is running, the port number is displayed. This command is an alias for STATUS MANAGER.

Syntax

INFO MANAGER
INFO MGR
SEND MANAGER

Use SEND MANAGER to retrieve the status of the active Manager process or to retrieve dynamic port information as configured in the Manager parameter file.

Syntax

SEND MANAGER
[CHILDSTATUS [DEBUG]]
[GETPORTINFO [DETAIL]]
[GETPURGEOLDEXTRACTS]

CHILDSTATUS [DEBUG]
Retrieves status information about processes started by Manager. DEBUG returns the port numbers that are allocated to processes.

GETPORTINFO [DETAIL]
By default, retrieves the current list of ports that have been allocated to processes and their corresponding process IDs. DETAIL provides a list of all the ports defined using the DYNAMICPORTLIST parameter.

GETPURGEOLDEXTRACTS
Displays information about trail maintenance rules that are set with the PURGEOLDEXTRACTS parameter in the Manager parameter file. For more information, see "PURGEOLDEXTRACTS for Extract and Replicat" on page 3-218.

Examples

Example 1
SEND MANAGER CHILDSTATUS DEBUG returns a child process status similar to the following. The basic CHILDSTATUS option returns the same display, without the Port column.

<table>
<thead>
<tr>
<th>ID</th>
<th>Group</th>
<th>Process</th>
<th>Retry</th>
<th>Retry Time</th>
<th>Start Time</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>ORAEXT</td>
<td>2400</td>
<td>0</td>
<td>None</td>
<td>2011/01/21 21:08:32</td>
<td>7840</td>
</tr>
<tr>
<td>2</td>
<td>ORAEXT</td>
<td>2245</td>
<td>0</td>
<td>None</td>
<td>2011/01/23 21:08:33</td>
<td>7842</td>
</tr>
</tbody>
</table>

Example 2
SEND MANAGER GETPORTINFO DETAIL returns a dynamic port list similar to the following.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Port</th>
<th>Error</th>
<th>Process</th>
<th>Assigned</th>
<th>Program</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>8000</td>
<td>0</td>
<td>2387</td>
<td>2011-01-01 10:30:23</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>8001</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>8002</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example 3
SEND MANAGER GETPURGEOLDEXTRACTS outputs information similar to the following.

<table>
<thead>
<tr>
<th>PurgeOldExtracts Rules</th>
<th>MinHours</th>
<th>MaxHours</th>
<th>MinFiles</th>
<th>MaxFiles</th>
<th>UseCP</th>
</tr>
</thead>
<tbody>
<tr>
<td>S:\GGS\DIRDAT\EXTRACT\P4*</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Y</td>
</tr>
<tr>
<td>S:\GGS\DIRDAT\EXTRACT\P2*</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Y</td>
</tr>
<tr>
<td>S:\GGS\DIRDAT\EXTRACT\P1*</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Y</td>
</tr>
<tr>
<td>S:\GGS\DIRDAT\REPTAIL\P4*</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Y</td>
</tr>
<tr>
<td>S:\GGS\DIRDAT\REPTAIL\P2*</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Y</td>
</tr>
</tbody>
</table>
Extract Trails

<table>
<thead>
<tr>
<th>Filename</th>
<th>Oldest_Chkpt_Seqno</th>
<th>IsTable</th>
<th>IsVamTwoPhaseCommit</th>
</tr>
</thead>
<tbody>
<tr>
<td>S:\GGS\DIRDAT\RT</td>
<td>3</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\REPTRAIL\P1\RT</td>
<td>13</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\REPTRAIL\P2\RT</td>
<td>13</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\REPTRAIL\P4\RT</td>
<td>13</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\EXTTRAIL\P1\ET</td>
<td>14</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\EXTTRAIL\P2\ET</td>
<td>14</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>S:\GGS\8020\DIRDAT\EXTTRAIL\P4\ET</td>
<td>14</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
START MANAGER

Use **START MANAGER** to start the Manager process. This applies to a non-clustered environment. In a Windows cluster, you should stop Manager from the Cluster Administrator.

**Syntax**

```
START MANAGER
[, CPU number]
[, PRI number]
[, HOMETERM device_name]
[, PROCESSNAME process_name]
```

**CPU number**
Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1 - 15 and -1 is default, which is assigned 1 higher than the last Manager started.

**PRI number**
Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers are 1 - 199 and -1 is the default, and is the same as the manager process priority.

**HOMETERM device_name**
Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/xxxxx form. The default is $zhome or the current session HOMETERM when $zhome is not defined.

**PROCESSNAME process_name**
Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/xxxxx form. The default is a system generated process name.

**Examples**

**Example 1**

```
START MANAGER, CPU 2, PRI 148, HOMETERM /G/zhome, PROCESSNAME $ogmgr
```
Use `STATUS MANAGER` to determine whether or not the Manager process is running and the process ID. If Manager is running, the port number is displayed.

**Syntax**

`STATUS MANAGER`
STOP MANAGER

Use STOP MANAGER to stop the Manager process. This applies to non-clustered environments. In a Windows cluster, Manager must be stopped through the Cluster Administrator.

Syntax

STOP MANAGER [!]

!  
(Exclamation point) Bypasses the prompt that confirms the intent to shut down Manager.
ADD EXTRACT

Use **ADD EXTRACT** to create an Extract group. Unless a **SOURCEISTABLE** task or an alias Extract is specified, **ADD EXTRACT** creates an online group that uses checkpoints so that processing continuity is maintained from run to run.

For DB2 for i, this command establishes a global start point for all journals and is a required first step. After issuing the **ADD EXTRACT** command, you can then optionally position any given journal at a specific journal sequence number by using the **ALTER EXTRACT** command with an appropriate journal option.

For Informix, this command initializes the position in the Informix logical log to capture the CDC record. When the first DML is processed, the Informix CDC record is contained in the logical log. Each record in the log is associated with a position, which is called LSN (Log Sequence Number). Only when initialization is complete will it be able to honor the positioning based on the LSN. The very first time you add an Extract, you must ensure that the has initialization completed (the duration depends on number of tables in your Extract parameter file) using the **INFO EXTRACT** command. Then ensure that the LSN number displayed matches the LSN displayed as the first record processed in the Extract report file. For example, if the LSN number returned by **INFO EXTRACT** is LSN: 892:0x1235018, then the message in the report file must be Position of first record processed LSN: 892:0x1235018, Apr 16, 2014 2:56:58 AM. When the initial Extract log positioning is complete, you can issue a stop or kill command **though not before**, doing so before results in any capture restart always starting from the EOF position of the database logs.

**Oracle GoldenGate** supports up to 5,000 concurrent Extract and Replicat groups per instance of **Oracle GoldenGate Manager**. At the supported level, all groups can be controlled and viewed in full with GGSCI commands such as the **INFO** and **STATUS** commands. **Oracle GoldenGate** recommends keeping the combined number of Extract and Replicat groups at the default level of 300 or below in order to manage your environment effectively.

This command cannot exceed 500 bytes in size for all keywords and input, including any text that you enter for the **DESC** option.

### Syntax for a Regular, Passive, or Data Pump Extract

```
ADD EXTRACT group_name
  {, SOURCEISTABLE |}
    , TRANLOG [bsds_name | LRI_number] |
    , INTEGRATED TRANLOG |
    , VAM |
    , EXTFIILESOURCE file_name |
    , EXTRACTSOURCE trail_name |
    , VAMTRAILSOURCE VAM_trail_name)
  [, BEGIN {NOW | yyyy-mm-dd[ hh:mm:ss[.cccccc]]} ]
  [, EXTSNO sequence_number, EXTRBA relative_byte_address ]
  [, EOF ]
  [, LSN value ]
  [, EXTRBA relative_byte_address ]
  [, EOF ]
  [, LSN value ]
  [, PAGE data_page, ROW row_ID ]
  [, SEQNO sequence_number ]
  [, SCN value ]
  [, THREADS n ]
  [, PASSIVE ]
  [, PARAMS file_name ]
```
group_name
The name of the Extract group. The name of an Extract group can contain up to eight characters. See Administering Oracle GoldenGate for Windows and UNIX for group naming conventions.

SOURCEISTABLE
Creates an Extract task that extracts entire records from the database for an initial load using the Oracle GoldenGate direct load method or the direct bulk load to SQL*Loader method. If SOURCEISTABLE is not specified, ADD EXTRACT creates an online change-synchronization process, and one of the other data source options must be specified. When using SOURCEISTABLE, do not specify any service options. Task parameters must be specified in the parameter file.

For more information about initial load methods, see Administering Oracle GoldenGate for Windows and UNIX.

TRANLOG [bsds_name | LRI_NUMBER]
Specifies the transaction log as the data source. Use this option for all databases except Informix and Teradata. TRANLOG requires the BEGIN option.

(DB2 on z/OS) You can use the bsds_name option for DB2 on a z/OS system to specify the Bootstrap Data Set file name of the transaction log, though it is not required and is not used. You do not need to change existing TRANLOG parameters.

(DB2 LUW) You can use the LRI_NUMBER option for DB2 LUW systems to specify the LRI record value for the checkpoint transaction log.

(Oracle) As of Oracle Standard or Enterprise Edition 11.2.0.3, this mode is known as classic capture mode. Extract reads the Oracle redo logs directly. See INTEGRATED TRANLOG for an alternate configuration.

INTEGRATED TRANLOG
Adds this Extract in integrated capture mode. In this mode, Extract integrates with the database logmining server, which passes logical change records (LCRs) directly to Extract. Extract does not read the redo log. Before using INTEGRATED TRANLOG, use the REGISTER EXTRACT command. For information about integrated capture, see Installing and Configuring Oracle GoldenGate for Oracle Database.

VAM
(Informix and Teradata) Specifies that the Extract API known as the Vendor Access Module (VAM) will be used to transfer change data to Extract.

EXTFILESOURCE file_name
Specifies an extract file as the data source. Use this option with a secondary Extract group (data pump) that acts as an intermediary between a primary Extract group and the target system.
For file_name, specify the relative or fully qualified path name of the file, for example dirdat\extfile or c:\ggs\dirdat\extfile.

**EXTRAILSOURCE trail_name**

Specifies a trail as the data source. Use this option with a secondary Extract group (data pump) that acts as an intermediary between a primary Extract group and the target system.

For trail_name, specify the relative or fully qualified path name of the trail, for example dirdat\aa or c:\ggs\dirdat\aa.

**VAMTRAILSOURCE VAM_trail_name**

(Teradata) Specifies a VAM trail. Use this option when using Teradata maximum protection mode.

For VAM_trail_name, specify the relative or fully qualified path name of the VAM trail to which the primary Extract group is writing. Use a VAM-sort Extract group to read the VAM trail and send the data to the target system.

**BEGIN {NOW | yyyy-mm-dd[ hh:mi:[ss[.cccccc]]]}**

Specifies a timestamp in the data source at which to begin processing.

- **NOW**
  - For all databases except DB2 LUW, NOW specifies the time at which the ADD EXTRACT command is issued.
  - For DB2 LUW, NOW specifies the time at which START EXTRACT takes effect. It positions to the first record that approximately matches the date and time. This is because the only log records that contain timestamps are the commit and abort transaction records, so the starting position can only be calculated relative to those timestamps. This is a limitation of the API that is used by Oracle GoldenGate.
  - Do not use NOW for a data pump Extract except to bypass data that was captured to the trail prior to the ADD EXTRACT statement.

- **yyyy-mm-dd[ hh:mi:[ss[.cccccc]]]**
  - A date and time (timestamp) in the given form. For an Oracle Extract in integrated mode, the timestamp value must be greater than the timestamp at which the Extract was registered with the database.
  - Positioning by timestamp in a SQL Server transaction log is affected by the following characteristics of SQL Server:
    - The timestamps recorded in the SQL Server transaction log use a 3.3333 microsecond (ms) granularity. This level of granularity may not allow positioning by time between two transactions, if the transactions began in the same 3.3333 ms time interval.
    - Timestamps are not recorded in every SQL Server log record, but only in the records that begin and commit the transaction, as well as some others that do not contain data.
    - SQL Server timestamps are not from the system clock, but instead are from an internal clock that is specific to the individual processors in use. This clock updates several times a second, but between updates it could get out of sync with the system clock. This further reduces the precision of positioning by time.
    - Timestamps recorded for log backup files may not precisely correspond to times recorded inside the backup (however this imprecision is less than a second).
Positioning to an LSN is precise. See LSN value.

- Positioning by timestamp in a Sybase transaction log is affected by the following characteristics of Sybase:

  Sybase only records timestamps in BEGIN and COMMIT records. Regardless of the actual timestamp that is specified, the start position will be the first record of the transaction that starts closest to, or at, the specified timestamp. The Extract report will display the following positions:

  **Positioning To**: This is the specified begin time, for example:
  
  Positioning to begin time Jan 1, 2011 12:13:33 PM.

  **Positioned To**: If the specified timestamp is less than, or equal to, the timestamp of the transaction log that contains the BEGIN or COMMIT record, Positioned To Page is displayed as in this example:
  
  2011-01-01 12:13:39  INFO  OGG-01516  Positioned to
  Page #: 0004460243
  Row #: 00111, Jan 1, 2011 12:13:38 PM.

  **First Record Position**: This is the position of the first valid record at, or after, the Positioned To position, as in this example:
  
  Page #: 0004460243
  Row #: 00111, Jan 1, 2011 12:13:38 PM.

**EXTSEQNO sequence_number, EXTRBA relative_byte_address**

Valid for a primary Extract in classic capture mode for Oracle, a primary Extract for NonStop SQL/MX, and a data pump Extract. Not supported for an Oracle Extract in integrated mode. Specifies either of the following:

- sequence number of an Oracle redo log and RBA within that log at which to begin capturing data.

- the NonStop SQL/MX TMF audit trail sequence number and relative byte address within that file at which to begin capturing data. Together these specify the location in the TMF Master Audit Trail (MAT).

- the file in a trail in which to begin capturing data (for a data pump). Specify the sequence number, but not any zeroes used for padding. For example, if the trail file is `c:\ggs\dirdat\aa000026`, you would specify EXTSEQNO 26. By default, processing begins at the beginning of a trail unless this option is used.

Contact Oracle Support before using this option. For more information, go to [http://support.oracle.com](http://support.oracle.com).

**EXTRBA relative_byte_address**

Valid for DB2 on z/OS. Specifies the relative byte address within a transaction log at which to begin capturing data. The required format is 0Xnnn, where nnn is a 1 to 20 digit hexadecimal number (the first character is the digit zero, and the second character can be upper or lower case letter x).

**EOF**

Valid for SQL Server and DB2 for i. Configures processing to start at the end of the log files (or journals) that the next record will be written to. Any active transactions will not be captured.
LSN value
Valid for Informix and SQL Server. Specifies the LSN in a transaction log at which to start capturing data. The specified LSN should exist in a log backup or the online log. An alias for this option is EXTLSN.

For SQL Server, an LSN is composed of one of these, depending on how the database returns it:

- Colon separated hex string (8:8:4) padded with leading zeroes and 0X prefix, as in 0X00000d7e:0000036b:01bd
- Colon separated decimal string (10:10:5) padded with leading zeroes, as in 0000003454:000000875:00445
- Colon separated hex string with 0X prefix and without leading zeroes, as in 0Xd7e:36b:1bd
- Colon separated decimal string without leading zeroes, as in 3454:875:445
- Decimal string, as in 345400000087500445

In the preceding, the first value is the virtual log file number, the second is the segment number within the virtual log, and the third is the entry number.

You can find the LSN for named transactions by using a query like:

```sql
select [Current LSN], [Transaction Name], [Begin Time]
from fn_dblog(null, null)
where Operation = 'LOP_BEGIN_XACT'
and [Begin Time] >= time
```

You can determine the time that a particular transaction started, then find the relevant LSN, and then position between two transactions with the same begin time.

EOF | LSN value
Valid for DB2 LUW and SQL Server. Specifies a start position in the transaction logs when Extract starts.

EOF
Configures processing to start at the active LSN in the log files. The active LSN is the position at the end of the log files that the next record will be written to. Any active transactions will not be captured.

LSN value
Configures processing to start at an exact LSN if a valid log record exists there. If one does not exist, Extract will abend. Note that, although Extract might position to a given LSN, that LSN might not necessarily be the first one that Extract will process. There are numerous record types in the log files that Extract ignores, such as DB2 internal log records. Extract will report the actual starting LSN to the Extract report file.

PAGE data_page, ROW row_ID
Valid for Sybase. Specifies a data page and row that together define a start position in a Sybase transaction log. Because the start position must be the first record of the transaction that starts closest to, or at, the specified PAGE and ROW, the Extract report will display the following positions:

- Positioning To is the position of the record that is specified with PAGE and ROW.
- Positioned To is the position where the first BEGIN record is found at, or after, the Positioning To position.
■ First Record Position is the position of the first valid record at, or after, the Positioned To position.

SEQNO sequence_number
Valid for DB2 for i. Starts capture at, or just after, a system sequence number, which is a decimal number up to 20 digits in length.

SCN value
Valid for Oracle. Starts Extract at the transaction in the redo log that has the specified Oracle system change number (SCN). This option is valid for Extract both in classic capture and integrated modes. For Extract in integrated mode, the SCN value must be greater than the SCN at which the Extract was registered with the database. For more information, see REGISTER EXTRACT.

PARAMS file_name
Specifies the full path name of an Extract parameter file in a location other than the default of dirprm within the Oracle GoldenGate directory.

REPORT file_name
Specifies the full path name of an Extract report file in a location other than the default of dirrpt within the Oracle GoldenGate directory.

THREADS n
Valid for classic capture mode. Specifies the number of producer threads that Extract maintains to read redo logs.

Required in an Oracle RAC configuration to specify the number of producer threads. These are the Extract threads that read the different redo logs on the various RAC nodes. The value must be the same as the number of nodes from which you want to capture redo data.

PASSIVE
Specifies that this Extract group runs in passive mode and can only be started and stopped by starting or stopping an alias Extract group on the target system.

Source-target connections will be established not by this group, but by the alias Extract from the target.

This option can be used for a regular Extract group or a data-pump Extract group. It should only be used by whichever Extract on the source system is the one that will be sending the data across the network to a remote trail on the target.

For instructions on how to configure passive and alias Extract groups, see Administering Oracle GoldenGate for Windows and UNIX.

DESC 'description'
Specifies a description of the group, such as 'Extracts account_tab on Serv1'. Enclose the description within single quotes. You may use the abbreviated keyword DESC or the full word DESCRIPTION.

CPU number
Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1 - 15 and -1 is default, which is assigned 1 higher than the last Manager started.

PRI number
Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers are 1 - 199 and -1 is the default, and is the same as the manager process priority.
**HOMETERM device_name**
Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/xxxxx form. The default is $zhome or the current session HOMETERM when $zhome is not defined.

**PROCESSNAME process_name**
Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/xxxxx form. The default is a system generated process name.

**SOCKSPROXY {host_name | IP_address}[:port] [PROXYCSALIAS credential_store_alias [PROXYCSDOMAIN credential_store_domain]]**
Use for an alias Extract. Specifies the DNS host name or IP address of the proxy server. You can use either one to define the host though you must use the IP address if your DNS server is unreachable. If you are using an IP address, use either an IPv6 or IPv4 mapped address, depending on the stack of the destination system. You must specify the PROXYCSALIAS. In addition, you can specify the port to use, and the credential store domain. For more information, see SOCKSPROXY.

**RMTNAME passive_extract_name**
Use for an alias Extract. Specifies the passive Extract name, if different from that of the alias Extract.

**Examples**

**Example 1**
The following creates an Extract group named finance that extracts database changes from the transaction logs. Extraction starts with records generated at the time when the group was created with ADD EXTRACT.

```sql
ADD EXTRACT finance, TRANLOG, BEGIN NOW
```

**Example 2**
The following creates an Extract group named finance that extracts database changes from Oracle RAC logs. Extraction starts with records generated at the time when the group was created. There are four RAC instances, meaning there will be four Extract threads.

```sql
ADD EXTRACT finance, TRANLOG, BEGIN NOW, THREADS 4
```

**Example 3**
The following creates an Extract group named finance that extracts database changes from the transaction logs. Extraction starts with records generated at 8:00 on January 21, 2011.

```sql
ADD EXTRACT finance, TRANLOG, BEGIN 2011-01-21 08:00
```

**Example 4**
The following creates an integrated capture Extract group.

```sql
ADD EXTRACT finance, INTEGRATED TRANLOG, BEGIN NOW
```

**Example 5**
The following creates an Extract group named finance that interfaces with a Teradata TAM in either maximum performance or maximum protection mode. No BEGIN point is used for Teradata sources.
ADD EXTRACT finance, VAM

**Example 6**
The following creates a VAM-sort Extract group named finance. The process reads from the VAM trail /ggs/dirdat/vt.

ADD EXTRACT finance, VAMTRAILSOURCE dirdat/vt

**Example 7**
The following creates a data-pump Extract group named finance. It reads from the Oracle GoldenGate trail c:\ggs\dirdat\lt.

ADD EXTRACT finance, EXTTAILSOURCE dirdat\lt

**Example 8**
The following creates an initial-load Extract named load.

ADD EXTRACT load, SOURCEISTABLE

**Example 9**
The following creates a passive Extract group named finance that extracts database changes from the transaction logs.

ADD EXTRACT finance, TRANLOG, BEGIN NOW, PASSIVE

**Example 10**
The following creates an alias Extract group named financeA. The alias Extract is associated with a passive extract named finance on source system sysA. The Manager on that system is using port 7800.

ADD EXTRACT financeA, RMTHOST sysA, MGRPORT 7800, RMTNAME finance

**Example 11**
The following examples start Extract at a specific Oracle system change number (SCN) in the redo log.

ADD EXTRACT finance TRANLOG SCN 123456
ADD EXTRACT finance INTEGRATED TRANLOG SCN 123456

**Example 12**
The following example creates an alias Extract specifying the host to use.

ADD EXTRACT apmp desc 'alias extract' RMHOST lc01abc MGRPORT 7813 RMTNAME ppmp SOCKS_PROXY lc02def:3128 PROXY_CSAlias proxyAlias

**Example 13**
The following example creates an Extract on a SQL/MX system.

ADD EXTRACT ext exttcp, CPU 3, PRI 148, HOMETERM $ZTN0.#PTHBP32, PROCESSNAME $ext1

**Example 14**
The following example creates an Extract on a DB2 LUW system.

ADD EXTRACT extcust, TRANLOG LRI 8066.322711
Use ALTER EXTRACT for the following purposes:

- To change the attributes of an Extract group created with the ADD EXTRACT command.
- To increment a trail to the next file in the sequence.
- To upgrade to an integrated capture configuration.
- To downgrade from an integrated capture configuration.
- To position any given IBM for i journal at a specific journal sequence number.
- To position any given Informix logical log at a specific LSN.

Before using this command, stop Extract with the STOP EXTRACT group_name command.

**Syntax**

```
ALTER EXTRACT group_name
[, ADD_EXTRACT_attribute]
[, TRANLOG LRI_number]
[, UPGRADE INTEGRATED TRANLOG]
[, DOWNGRADE INTEGRATED TRANLOG [THREADS number]]
[, THREAD number]
[, LSN value]
[, SCN value]
[, ETROLLOVER]
```

The following ALTER EXTRACT options are supported for DB2 for i to position Extract for a given journal:

```
ALTER EXTRACT {BEGIN {NOW | yyyy-mm-dd[, hh:mi[,ss[,cccccc]]]} | [JOURNAL journal_library/journal_name [JRNRCV receiver_library/receiver_name]] | [JRNRCV receiver_library/receiver_name] | EOF | [JOURNAL journal_library/journal_name [JRNRCV receiver_library/receiver_name]] | [JRNRCV receiver_library/receiver_name] | [JRNRCV receiver_library/receiver_name]]
```

**ADD_EXTRACT_attribute**

You can change any of the attributes specified with the ADD EXTRACT command, except for the following:

- Altering an Extract specified with the EXTTRAILSOURCE option.
- Altering the number of RAC threads specified with the THREADS option.

For these exceptions, delete the Extract group and then add it again.

If using the BEGIN option, do not combine other options in the statement. Issue separate statements, for example:

```
ALTER EXTRACT finance, BEGIN 2011-01-01
ALTER EXTRACT finance, ETROLLOVER
ALTER EXTRACT finance, SCN 789000
```
If using the SCN or BEGIN option for Integrated Extract, it requires a DBLOGIN, and the SCN or timestamp value specified cannot be below the outbound server's first SCN or timestamp. To find the outbound server's first SCN, issue the following command:

```
INFO EXTRACT group_name, SHOWCH DETAIL
```

The first SCN value is listed as shown in the following example:

Integrated Extract outbound server first scn: 0.665884 (665884)

**TRANLOG LRI_number**

(DB2 LUW) You can use the LRI_number option for DB2 LUW systems to specify the LRI record value for the checkpoint transaction log.

**UPGRADE INTEGRATED TRANLOG**

Upgrades the Extract group from classic capture to integrated capture. To support the upgrade, the transaction log that contains the start of the oldest open transaction must be available on the source or downstream mining system. For instructions on making the transition from classic to integrated capture, see the full procedure in *Administering Oracle GoldenGate for Windows and UNIX*.

**DOWNGRADE INTEGRATED TRANLOG [THREADS number]**

Downgrades the Extract group from integrated capture to classic capture. When downgrading on a RAC system, the THREADS option must be used to specify the number of RAC threads. On a non-RAC system, you can optionally specify THREADS 1 to cause the downgraded classic Extract to run in threaded mode with one thread, which is similar to doing an ADD EXTRACT with THREADS 1 on a non-RAC system.

See *Administering Oracle GoldenGate for Windows and UNIX* for the full procedure for performing the transition from integrated to classic capture.

To support the downgrade, the transaction log that contains the start of the oldest open transaction must be available on the source or downstream mining system. For information about integrated capture, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

**THREAD number**

Valid for classic capture mode. In an Oracle RAC configuration, alters Extract only for the specified redo thread. Only one thread number can be specified.

**LSN value**

Valid for Informix. Repositions Extract to by the specified LSN to begin from the EOF in the logical log. This option is valid classic capture mode.

**SCN value**

Valid for Oracle. Repositions Extract to the transaction in the redo log that has the specified Oracle system change number (SCN). This option is valid both for integrated capture mode and classic capture mode.

**ETROLLOVER**

Causes Extract to increment to the next file in the trail sequence when restarting. For example, if the current file is ET000002, the current file will be ET000003 when Extract restarts. A trail can be incremented from 000001 through 999999, and then the sequence numbering starts over at 000000.
**CPU number**
Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1-15 and -1 is default, which is assigned 1 higher than the last Manager started.

**PRI number**
Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers are 1-199 and -1 is the default, and is the same as the manager process priority.

**HOMETERM device_name**
Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/xxxxx form. The default is $zhome or the current session Hometerm when $zhome is not defined.

**PROCESSNAME process_name**
Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/xxxxx form. The default is a system generated process name.

```
BEGIN {NOW | yyyy-mm-dd[ hh:mi:[ss[.cccccc]]}}
JOURNAL journal_library/journal_name
  [JRNRCV receiver_library/ receiver_name] |
, EOF [JOURNAL journal_library/journal_name
  [JRNRCV receiver_library/receiver_name] |]
, SEQNO sequence_number [JOURNAL journal_library/journal_name
  [JRNRCV receiver_library/receiver_name]]
```

These IBM for i options allow journal-specific Extract positioning after the global start point is issued with `ADD EXTRACT`. A specific journal position set with `ALTER EXTRACT` does not affect any global position that was previously set with `ADD EXTRACT` or `ALTER EXTRACT`; however a global position set with `ALTER EXTRACT overrides any specific journal positions that were previously set in the same Extract configuration.

---

**Note:** SEQNO, when used with a journal in `ALTER EXTRACT`, is the journal sequence number that is relative to that specific journal, not the system sequence number that is global across journals.

---

**Examples**

**Example 1**
The following alters Extract to start processing data from January 1, 2011.

```
ALTER EXTRACT finance, BEGIN 2011-01-01
```

**Example 2**
The following alters Extract to start processing at a specific location in the trail.

```
ALTER EXTRACT finance, EXTSEQNO 26, EXTRBA 338
```

**Example 3**
The following alters Extract in an Oracle RAC environment, and applies the new begin point only for redo thread 4.

```
ALTER EXTRACT accounts, THREAD 4, BEGIN 2011-01-01
```
Example 4
The following alters Extract in a SQL Server environment to start at a specific LSN.
ALTER EXTRACT sales, LSN 3454:875:445

Example 5
The following alters Extract to increment to the next file in the trail sequence.
ALTER EXTRACT finance, ETROLLOVER

Example 6
The following alters Extract to upgrade to integrated capture.
ALTER EXTRACT finance, UPGRADE INTEGRATED TRANLOG

Example 7
The following alters Extract to downgrade to classic capture in a RAC environment.
ALTER EXTRACT finance, DOWNGRADE INTEGRATED TRANLOG THREADS 3

Example 8
The following alters Extract in an Oracle environment to start processing data from source database SCN 778899.
ALTER EXTRACT finance, SCN 778899

Example 9
The following shows ALTER EXTRACT for an IBM for i journal start point.
ALTER EXTRACT finance, SEQNO 1234 JOURNAL accts/acctsjrn

Example 10
The following shows ALTER EXTRACT for an IBM for i journal and receiver start point.
ALTER EXTRACT finance, SEQNO 1234 JOURNAL accts/acctsjrn JRNRCV accts/jrnrcv0005

Example 11
The following alters an Extract on a SQL/MX NonStop platform.
ALTER EXTRACT exttcp, CPU 1, PRI 150, HOMETERM /G/zhome, PROCESSNAME $ose01

Example 12
The following example alters an Extract on a DB2 LUW system.
ALTER EXTRACT extcust, TRANLOG LRI 8066.322711
CLEANUP EXTRACT

Use CLEANUP EXTRACT to delete run history for the specified Extract group. The cleanup keeps the last run record intact so that Extract can resume processing from where it left off. Before using this command, stop Extract by issuing the STOP EXTRACT command.

Syntax

CLEANUP EXTRACT group_name [ , SAVE count]

group_name
The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* cleans up all Extract groups whose names start with T.

SAVE count
Excludes the specified number of the most recent records from the cleanup.

Examples

Example 1
The following deletes all but the last record.

CLEANUP EXTRACT finance

Example 2
The following deletes all but the most recent five records.

CLEANUP EXTRACT *, SAVE 5
DELETE EXTRACT

Use DELETE EXTRACT to delete an Extract group. This command deletes the checkpoint file that belongs to the group, but leaves the parameter file intact. You can then re-create the group or delete the parameter file as needed.

Before using DELETE EXTRACT, stop Extract with the STOP EXTRACT command.

To delete the trail files that are associated with the Extract group, delete them manually through the operating system.

Syntax

DELETE EXTRACT group_name [!]

*group_name*

The name of an Extract group or a wildcard specification (*) to specify multiple groups. For example, T* deletes all Extract groups whose names start with T.

*!*

(Exclamation point) Deletes all Extract groups associated with a wildcard without prompting.
INFO EXTRACT

Use **INFO EXTRACT** to view the following information.

- The status of Extract (STARTING, RUNNING, STOPPED or ABENDED). **STARTING** means that the process has started but has not yet locked the checkpoint file for processing.
- Approximate Extract lag.
- Checkpoint information.
- Process run history.
- The trail(s) to which Extract is writing.
- Status of upgrade to, or downgrade from, integrated capture

Extract can be running or stopped when **INFO EXTRACT** is issued. In the case of a running process, the status of **RUNNING** can mean one of the following:

- **Active**: Running and processing (or able to process) data. This is the normal state of a process after it is started.
- **Suspended**: The process is running, but suspended due to an **EVENTACTIONS SUSPEND** action. In a suspended state, the process is not active, and no data can be processed, but the state of the current run is preserved and can be continued by issuing the **SEND EXTRACT** command with the **RESUME** option in GGSCI. The RBA in the **INFO** command reflects the last checkpointed position before the suspend action. To determine whether the state is active or suspended, issue the **SEND EXTRACT** command with the **STATUS** option.

The basic command displays information only for online (continuous) Extract processes. Tasks are excluded.

**About Extract Lag**

The **Checkpoint Lag** field of the **INFO EXTRACT** output reflects the lag, in seconds, at the time that the last checkpoint was written to the trail. For example, if the following is true...

- Current time = 15:00:00
- Last checkpoint = 14:59:00
- Timestamp of the last record processed = 14:58:00

...then the lag is reported as 00:01:00 (one minute, the difference between 14:58 and 14:59).

A lag value of **UNKNOWN** indicates that the process could be running but has not yet processed records, or that the source system’s clock is ahead of the target system’s clock (due to clock imperfections, not time zone differences).

For more precise lag information, use **LAG EXTRACT** (see "LAG EXTRACT" on page 1-32).

**Syntax**

**INFO EXTRACT** group_name
[, SHOWCH [n]]
[, DETAIL]
[, TASKS | ALLPROCESSES]
INFO EXTRACT

[, UPGRADE | DOWNGRADE]

**group_name**
The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* shows information for all Extract groups whose names start with T.

**SHOWCH [n]**
The basic command shows information about the current Extract checkpoints. Extract checkpoint positions are composed of read checkpoints in the data source and write checkpoints in the trail. The trail type (RMTTRAIL or EXTRAIL) is also noted.

Optionally, specify a value for n to include the specified number of previous checkpoints as well as the current one.

---

**Note:** You might see irregular indents and spacing in the output. This is normal and does not affect the accuracy of the information.

---

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints, including descriptions of the types of checkpoints made by each process and the internal metadata entries that are included in the display.

**DETAIL**
Displays the following:
- Extract run history, including start and stop points in the data source, expressed as a time.
- Trails to which Extract is writing.

See Example 5 for sample output of **DETAIL**.

**TASKS**
Displays only Extract tasks. Tasks that were specified by a wildcard argument are not displayed by **INFO EXTRACT**.

**ALLPROCESSES**
Displays all Extract groups, including tasks.

**UPGRADE | DOWNGRADE**
Valid for an Oracle database only.
- **UPGRADE** displays whether the Extract can be upgraded from classic capture mode to integrated capture mode.
- **DOWNGRADE** displays whether the Extract can be downgraded from integrated capture mode to classic capture mode.

If Extract cannot be upgraded or downgraded, the reason why is displayed.
A wildcarded Extract name is not allowed with this option.

Before using this command, issue the **DBLOGIN** command.

**Examples**

**Example 1**

INFO EXTRACT fin*, SHOWCH
Example 2
INFO EXTRACT *, TASKS

Example 3 (Oracle only)
INFO EXTRACT finance UPGRADE

Example 4
The following example shows basic INFO EXTRACT output.

INFO EXTRACT EXTCUST Last Started 2011-01-05 16:09 Status RUNNING
Checkpoint Lag 00:01:30 (updated 97:16:45 ago)
Log Read Checkpoint File /rdms/data/oradata/redo03a.log
2011-01-05 16:05:17 Seqno 2952, RBA 7598080

Example 5
The following is an example of the output of INFO EXTRACT with DETAIL.

INFO EXTRACT ORAEXT Last Started 2011-01-15 16:16 Status STOPPED
Checkpoint Lag 00:00:00 (updated 114:24:48 ago)
Log Read Checkpoint File C:\ORACLE\ORADATA\ORA920\REDO03.LOG
2011-01-15 16:17:53 Seqno 46, RBA 3757568

KILL EXTRACT

Use KILL EXTRACT to kill an Extract process running in regular or PASSIVE mode. Use this command only if a process cannot be stopped gracefully with the STOP EXTRACT command. The Manager process will not attempt to restart a killed Extract process.

Syntax

KILL EXTRACT group_name

*group_name*

The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* kills all Extract processes whose group names start with T.

Example

KILL EXTRACT finance
LAG EXTRACT

Use LAG EXTRACT to determine a true lag time between Extract and the data source. LAG EXTRACT calculates the lag time more precisely than INFO EXTRACT because it communicates with Extract directly, rather than reading a checkpoint position in the trail.

For Extract, lag is the difference, in seconds, between the time that a record was processed by Extract (based on the system clock) and the timestamp of that record in the data source.

Syntax

LAG EXTRACT group_name

- group_name
  The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* determines lag time for all Extract groups whose names start with T.

Examples

Example 1
LAG EXTRACT *

Example 2
LAG EXTRACT *fin*

Example 3
The following is sample output for LAG EXTRACT.

Sending GETLAG request to EXTRACT CAPTPCC...
Last record lag: 2 seconds.
At EOF, no more records to process.
REGISTER EXTRACT

Use REGISTER EXTRACT to register a primary Extract group with an Oracle database to:

- Enable integrated capture mode
- Specify options for integrated capturing from a multitenant container database
- Enable Extract in classic capture mode to work with Oracle Recovery Manager to retain the archive logs needed for recovery

REGISTER EXTRACT is not valid for a data pump Extract.

To unregister an Extract group from the database, use the UNREGISTER EXTRACT command (see "UNREGISTER EXTRACT" on page 1-55).

See Installing and Configuring Oracle GoldenGate for Oracle Database for more information about using REGISTER EXTRACT.

Syntax

For classic Extract:

REGISTER EXTRACT group_name LOGRETENTION

For integrated Extract:

REGISTER EXTRACT group_name DATABASE
[CONTAINER (container[, ...]) | ADD CONTAINER (container[, ...]) | DROP CONTAINER (container[, ...])]
[SCN system_change_number]
{SHARE [ AUTOMATIC | extract | NONE]}

group_name
The name of the Extract group that is to be registered. Do not use a wildcard.

DATABASE
CONTAINER (container[, ...]) | ADD CONTAINER (container[, ...]) | DROP CONTAINER (container[, ...])

Without options, DATABASE enables integrated capture from a non-CDB database for the Extract group. In this mode, Extract integrates with the database logmining server to receive change data in the form of logical change records (LCR). Extract does not read the redo logs. Extract performs capture processing, transformation, and other requirements. The DML filtering is performed by the Logmining server. For support information and configuration steps, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Before using REGISTER EXTRACT with DATABASE, use the DBLOGIN command for all extracts with the privileges granted using the dbms_goldengate_auth.grant_admin_privilege procedure. If you have a downstream configuration, then you must also issue the MININGDBLOGIN command. If the source database you are registering is a CDB database and Extract will fetch data, then grant_admin_privilege must be called with the CONTAINER=>'ALL' parameter.
After using **REGISTER EXTRACT**, use **ADD EXTRACT** with the **INTEGRATED TRANLOG** option to create an Extract group of the same name. You must register an Extract group before adding it.

**CONTAINER** *(container[, ...])*  
Applies the registration to a list of one or more pluggable databases (containers) of a multitenant container database (CDB). Specify one or more pluggable databases as a comma-delimited list within parentheses, for example: **CONTAINER (pdb1, pdb2, pdb3)**. All of the pluggable databases must exist in the database, and all names must be explicit, not wildcarded.

**ADD CONTAINER** *(container[, ...])*  
Adds the specified pluggable database to an existing Extract capture configuration. Specify one or more pluggable databases as a comma-delimited list within parentheses, for example: **ADD CONTAINER (pdb1, pdb2, pdb3)**. Before issuing **REGISTER EXTRACT** with this option, stop the Extract group.

For Oracle, adding CONTAINERs at particular SCN on an existing Extract is not supported.

**DROP CONTAINER** *(container[, ...])*  
Drops the specified pluggable database from an existing Extract capture configuration. Specify one or more pluggable databases as a comma-delimited list within parentheses, for example: **DROP CONTAINER (pdb1, pdb2, pdb3)**. Before issuing **REGISTER EXTRACT** with this option, stop the Extract group.

**LOGRETENTION**  
Valid for classic Extract only. Enables an Extract group in classic capture mode to work with Oracle Recovery Manager (RMAN) to retain the logs that Extract needs for recovery. **LOGRETENTION** is ignored if the Extract group is configured for integrated capture.

**LOGRETENTION** creates an underlying Oracle Streams capture process that is dedicated to the Extract group and has a similar name. This capture is used only for the purpose of log retention.

The logs are retained from the time that **REGISTER EXTRACT** is issued, based on the current database SCN. The log-retention feature is controlled with the **LOGRETENTION** option of the **TRANLOGOPTIONS** parameter.

Before using **REGISTER EXTRACT** with **LOGRETENTION**, issue the **DBLOGIN** command with the privileges shown in "**DBLOGIN**" on page 1-116.

**SCN system_change_number**  
Registers Extract to begin capture at a specific system change number (SCN) in the past. Without this option, capture begins from the time that **REGISTER EXTRACT** is issued. The specified SCN must correspond to the begin SCN of a dictionary build operation in a log file. You can issue the following query to find all valid SCN values:

```sql
SELECT first_change#
FROM v$archived_log
WHERE dictionary_begin = 'YES' AND
  standby_dest = 'NO' AND
  name IS NOT NULL AND
  status = 'A';
```

When used alone, the SCN value is the beginning SCN of the dictionary build operation in a log file.
When used in conjunction with `SHARE AUTOMATIC` or `SHARE extract_name`, then the specified SCN is the start_scn for the capture session and has the following restrictions:

- Should be lesser than or equal to the current SCN.
- Should be greater than the minimum (first SCN) of the existing captures.

```
{SHARE [AUTOMATIC | extract | NONE]}
```

Registers the extract to return to an existing LogMiner data dictionary build with a specified SCN creating a clone. This allows for faster creation captures by leveraging existing dictionary builds.

SHARE cannot be used on a CDB.

The following GGSCI commands are supported:

```
REGISTER EXTRACT extract with database SCN ### SHARE AUTOMATIC
REGISTER EXTRACT extract with database SCN ### SHARE extract
REGISTER EXTRACT extract with database SHARE NONE
REGISTER EXTRACT extract with database SCN ### SHARE NONE
```

Or

```
REGISTER EXTRACT extract WITH DATABASE SHARE NONE
REGISTER EXTRACT extract WITH DATABASE SCN ### SHARE NONE
```

In contrast, the following GGSCI commands are *not* supported in a downstream configuration:

```
REGISTER EXTRACT extract WITH DATABASE SHARE AUTOMATIC
REGISTER EXTRACT extract WITH DATABASE SHARE extract
```

**AUTOMATIC**

Clone from the existing closest capture. If no suitable clone candidate is found, then a new build is created.

**extract**

Clone from the capture session associated for the specified extract. If this is not possible, then an error occurs the register does not complete.

**NONE**

Does not clone or create a new build; this is the default.

In a downstream configuration, the `SHARE` clause *must* be used in conjunction with the `SCN` clause when registering for Extract.

### Examples

**Example 1**

```
REGISTER EXTRACT sales LOGRETENTION
```

**Example 2**

```
REGISTER EXTRACT sales DATABASE
```
Example 3
REGISTER EXTRACT sales DATABASE CONTAINER (sales, finance, hr)

Example 4
REGISTER EXTRACT sales DATABASE ADD CONTAINER (customers)

Example 5
REGISTER EXTRACT sales DATABASE DROP CONTAINER (finance)

Example 6
REGISTER EXTRACT sales DATABASE SCN 136589
The beginning SCN of the dictionary build is 136589.

Example 7
REGISTER EXTRACT sales DATABASE SCN 67000 SHARE ext2
The valid start SCN, 67000 in this case; it is not necessarily the current SCN.

Example 8
REGISTER EXTRACT sales DATABASE CONTAINER (sales, finance, hr) SCN 136589
SEND EXTRACT

Use **SEND EXTRACT** to communicate with a running Extract process. The request is processed as soon as Extract is ready to accept commands from users.

**Syntax**

```
SEND EXTRACT group_name, { 
  BR {BRINTERVAL interval | 
    BRSTART | 
    BRSTOP | 
    BRCHECKPOINT {IMMEDIATE | IN n[H|M] | AT yyyy-mm-dd hh:mm[:ss]}} | 
  BR BRFSOPTION { MS_SYNC | MS_ASYNC } | 
  CACHEMGR {CACHESTATS | CACHEQUEUES | CACHEPOOL n} | 
  CACHEMGR CACHEFSOPTION { MS_SYNC | MS_ASYNC } | 
  FORCESTOP | 
  FORCETRANS transaction_ID [THREAD n] [FORCE] | 
  GETLAG | 
  GETTCPSTATS | 
  LOGEND | 
  LOGSTATS | 
  REPORT | 
  RESUME | 
  ROLLEROVER | 
  SHOWTRANS [transaction_ID] [THREAD n] [COUNT n] 
    [DURATION duration unit] [TABULAR] 
    [FILE file_name [DETAIL]] | 
  SKIPTRANS transaction_ID [THREAD n] [FORCE] | 
  STATUS | 
  STOP | 
  TRACE[2] file_name | 
  TRACE[2] OFF | 
  TRACE OFF file_name | 
  TRACEINIT | 
  TRANLOGOPTIONS {PREPAREFORUPGRADETOIE | NOPREPAREFORUPGRADETOIE} | 
  TRANLOGOPTIONS {PURGEORPHANEDTRANSACTIONS | NOPURGEORPHANEDTRANSACTIONS} | 
  TRANLOGOPTIONS TRANSCLEANUPFREQUENCY minutes | 
  VAMMESSAGE ‘Teradata_command’ | 
  VAMMESSAGE {‘ARSTATS’ | ‘INCLUDELIST [filter]’ | ‘FILELIST [filter]’ | ‘EXCLUDELIST [filter]’} | 
  VAMMESSAGE ‘OPENTRANS’ 
}
```

**group_name**
The name of the Extract group or a wildcard (*) to specify multiple groups. For example, T* sends the command to all Extract processes whose group names start with T. If an Extract is not running, an error is returned.

**BR**

```
BR {BRINTERVAL interval | BRSTART | BRSTOP | 
  BRCHECKPOINT {IMMEDIATE | IN n[H|M] | AT yyyy-mm-dd hh:mm[:ss]}}
```

Sends commands that affect the Bounded Recovery mode of Extract.

**BRINTERVAL interval**
Sets the time between Bounded Recovery checkpoints. Valid values are from 20 minutes to 96 hours specified as M for minutes or H for hours, for example 20M or 2H. The default interval is 4 hours.
**BRSTART**
Starts Bounded Recovery. This command should only be used under direction of Oracle Support.

**BRSTOP**
 Stops Bounded Recovery for the run and for recovery. Consult Oracle Support before using this option. In most circumstances, when there is a problem with Bounded Recovery, it turns itself off.

**BRCHECKPOINT {IMMEDIATE | IN n[H|M] | AT yyyy-mm-dd[ hh:mm[:ss]]}**
Sets the point at which a bounded recovery checkpoint is made. IMMEDIATE issues the checkpoint immediately when SEND EXTRACT is issued. IN issues the checkpoint in the specified number of hours or minutes from when SEND EXTRACT is issued. AT issues the checkpoint at exactly the specified time.

**BR BRFSOPTION {MS_SYNC | MS_ASYNC}**
Performs synchronous/asynchronous writes of the mapped data in Bounded Recovery.

**MS_SYNC**
Bounded Recovery writes of mapped data are synchronized for I/O data integrity completion.

**MS_ASYNC**
Bounded Recovery writes of mapped data are initiated or queued for servicing.

**CACHEMGR {CACHESTATS | CACHEQUEUES | CACHEPOOL n}**
Returns statistics about the Oracle GoldenGate memory cache manager. CACHESTATS should only be used as explicitly directed by Oracle Support.  

**CACHESTATS**
Returns statistics for virtual memory usage and file caching.

**CACHEQUEUES**
Returns statistics for the free queues only.

**CACHEPOOL n**
Returns statistics for the specified object pool only.

**CACHEMGR CACHEFSOPTION {MS_SYNC | MS_ASYNC}**
Performs synchronous or asynchronous writes of the mapped data in the Oracle GoldenGate memory cache manager.

**FORCESTOP**
Forces Extract to stop, bypassing any notifications. This command will stop the process immediately.

**FORCETRANST transaction_ID [THREAD n] [FORCE]**
Valid for MySQL, Oracle, SQL/MX, SQL Server, Sybase.

Forces Extract to write a transaction specified by its transaction ID number to the trail as a committed transaction. FORCETRANST does not commit the transaction to the source database. It only forces the existing data to the trail so that it is processed (with an implicit commit) by Replicat. You can repeat FORCETRANST for other transactions in order of their age. Note that forcing a transaction to commit to the trail (and therefore the target database) may cause data discrepancies if the transaction is rolled back by the source user applications.
After using `FORCETRANS`, wait at least five minutes if you intend to issue `SEND EXTRACT` with `FORCESTOP`. Otherwise, the transaction will still be present.

If `FORCETRANS` is used immediately after Extract starts, you might receive an error message that asks you to wait and then try the command again. This means that no other transactions have been processed yet by Extract. Once another transaction is processed, you will be able to force the transaction to trail.

**transaction_ID**

The ID of the transaction. Get the transaction ID number with `SHOWTRANS` or from an Extract runtime message. Extract ignores any data added to the transaction after this command is issued. A confirmation prompt must be answered unless `FORCE` is used. To use `FORCETRANS`, the specified transaction must be the oldest one in the list of transactions shown with `SHOWTRANS` with the exception of SQL/MX. For SQL/MX, the transaction does not have to be the oldest outstanding.

**THREAD n**

Valid only for Oracle.

Use `THREAD n` to specify which thread generated the transaction in an Oracle RAC environment if there are duplicate transaction IDs across threads.

**FORCE**

Valid for Oracle, SQL/MX, SQL Server, Sybase. Not valid for MySQL.

Use `FORCE` to bypass the confirmation prompt.

**GETLAG**

Determines a true lag time between Extract and the data source. Returns the same results as `LAG EXTRACT` (see "LAG EXTRACT" on page 1-32).

**GETTCPSTATS**

Displays statistics about network activity between Extract and the target system. The statistics include:

- Local and remote IP addresses.
- Inbound and outbound messages, in bytes and bytes per second.
- Number of receives (inbound) and sends (outbound). There will be at least two receives per inbound message: one for the length and one or more for the data.
- Average bytes per send and receive.
- Send and receive wait time: Send wait time is how long it takes for the write to TCP to complete. The lower the send wait time, the better the performance over the network. Receive wait time is how long it takes for a read to complete. Together, the send and receive wait times provide a rough estimate of network round trip time. These are expressed in microseconds.
- Status of data compression (enabled or not).
- Uncompressed bytes and compressed bytes: When compared (uncompressed to compressed), these comprise the compression ratio, meaning how many bytes there were before and after compression. You can compare the compression ratio with the bytes that are being compressed per second to determine if the compression rate is worth the cost in terms of resource and network consumption.

The `TCPBUFSIZE` option of `RMTHOST` and `RMTHOSTOPTIONS` controls the size of the TCP buffer for uncompressed data. What actually enters the network will be less than this size if compression is enabled. `GETTCPSTATS` shows post-compression throughput.
LOGEND
Confirms whether or not Extract has processed all of the records in the data source.

LOGSTATS
Valid only for Oracle.

Instructs Extract to issue a report about the statistics that are related to the processing of data from the Oracle redo log files. Extract uses an asynchronous log reader that reads ahead of the current record that Extract is processing, so that the data is available without additional I/O on the log files. The processing is done through a series of read/write queues. Data is parsed by a producer thread at the same time that additional data is being read from the log file by a reader thread. Thus, the reason for the term “read-ahead” in the statistics.

The statistics are:

- **AsyncReader.Buffers:** There is a field like this for each buffer queue that contains captured redo data. It shows the size, the number of records in it, and how long the wait time is before the data is processed. These statistics are given for write operations and read operations on the queue.

- **REDO read ahead buffers:** The number of buffers that are being used to read ahead asynchronously.

- **REDO read ahead buffer size:** The size of each buffer.

- **REDO bytes read ahead for current redo:** Whether read-ahead mode is on or off for the current redo log file (value of **ON** or **OFF**).

- **REDO bytes read:** The number of bytes read from all redo log files that are associated with this instance of Extract.

- **REDO bytes read ahead:** The number of bytes that were processed by the read-ahead mechanism.

- **REDO bytes unused:** The number of read-ahead bytes that were subsequently dropped as the result of Extract position changes or stale reads.

- **REDO bytes parsed:** The number of bytes that were processed as valid log data.

- **REDO bytes output:** The number of bytes that were written to the trail file (not including internal Oracle GoldenGate overhead).

REPORT
Generates an interim statistical report to the Extract report file. The statistics that are displayed depend upon the configuration of the **STATOPTIONS** parameter when used with the **RESETREPORTSTATS | NORESETREPORTSTATS** option. See “**STATOPTIONS**” on page 3-301.

RESUME
Resumes (makes active) a process that was suspended by an **EVENTACTIONS SUSPEND** event. The process resumes normal processing from the point at which it was suspended.

ROLLOVER
Causes Extract to increment to the next file in the trail when restarting. For example, if the current file is **ET000002**, the current file will be **ET000003** after the command executes. A trail can be incremented from **000001** through **999999**, and then the sequence numbering starts over at **000000**.
SHOWTRANS [transaction_ID] [THREAD n] [COUNT n] [DURATION duration unit] [TABULAR] | [FILE file_name [DETAIL]]
Valid for MySQL, Oracle, SQL/MX, SQL Server, Sybase.

Displays information about open transactions. SHOWTRANS shows any of the following, depending on the database type:

- Process checkpoint (indicating the oldest log needed to continue processing the transaction in case of an Extract restart). See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints.
- Transaction ID
- Extract group name
- Redo thread number
- Timestamp of the first operation that Oracle GoldenGate extracts from a transaction (not the actual start time of the transaction)
- System change number (SCN)
- Redo log number and RBA
- Status (Pending COMMIT or Running). Pending COMMIT is displayed while a transaction is being written after a FORCETRANS was issued.

Without options, SHOWTRANS displays all open transactions that will fit into the available buffer. See Example 7 for sample output of SHOWTRANS. To further control output, see the following options.

**transaction_ID**
Limits the command output to a specific transaction.

**THREAD n**
Valid only for Oracle.

Constrains the output to open transactions against a specific Oracle RAC thread. For *n*, use a RAC thread number that is recognized by Extract.

**COUNT n**
Constrains the output to the specified number of open transactions, starting with the oldest one. Valid values are 1 to 1000.

**DURATION duration unit**
Restricts the output to transactions that have been open longer than the specified time, where:

*duration* is the length of time expressed as a whole number.

*unit* is one of the following to express seconds, minutes, hours, or days:

S|SEC|SECS|SECOND|SECONDS
M|MIN|MINS|MINUTE|MINUTES
H|HOUR|HOURS
D|DAY|DAYS

For Sybase, which does not put a timestamp on each record, the duration is not always precise and depends on the time information that is stored in the transaction log for the BEGIN and COMMIT records.

**TABULAR**
Valid only for Oracle.
Generates output in tabular format similar to the default table printout from SQL*Plus. The default is field-per-row.

**FILE file_name [DETAIL]**
Valid only for Oracle and SQL Server. Not valid for MySQL, SQL/MX, Sybase.

Forces Extract to write the transaction information to the specified file. There is no output to the console.

For Oracle, you can write a hex and plain-character dump of the data by using **FILE** with **DETAIL**. This dumps the entire transaction from memory to the file. Viewing the data may help you decide whether to skip the transaction or force it to the trail.

---

**Note:** Basic detail information is automatically written to the report file at intervals specified by the **WARNLONGTRANS CHECKINTERVAL** parameter.

---

**SKIPTRANS transaction_ID [THREAD n] [FORCE]**
Valid for MySQL, Oracle, SQL/MX, SQL Server, Sybase.

Forces Extract to skip the specified transaction, thereby removing any current data from memory and ignoring any subsequent data. A confirmation prompt must be answered unless **FORCE** is used. After using **SKIPTRANS**, wait at least five minutes if you intend to issue **SEND EXTRACT** with **FORCESTOP**. Otherwise, the transaction will still be present. Note that skipping a transaction may cause data loss in the target database.

---

**Note:** To use **SKIPTRANS**, the specified transaction must be the oldest one in the list of transactions shown with **SHOWTRANS** with the exception of SQL/MX. For SQL/MX, the transaction does not have to be the oldest outstanding. You can repeat the command for other transactions in order of their age.

---

**transaction_ID**
The transaction ID number. Get the ID number with **SHOWTRANS** or from an Extract runtime message.

**THREAD n**
Valid only for Oracle.

Use **THREAD n** to specify which thread generated the transaction in an Oracle RAC environment if there are duplicate transaction IDs. **SKIPTRANS** specifies the checkpoint index number, not the actual thread number. To specify the correct thread, issue the **INFO EXTRACT group_name SHOWCH** command, and then specify the **READ** checkpoint index number that corresponds to the thread number that you want to skip. See the examples for details. See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints.

**FORCE**
Valid for Oracle, SQL/MX, SQL Server, Sybase. Not valid for MySQL.

Use **FORCE** to bypass the prompt that confirms your intent to skip the transaction.

---

**STATUS**
Returns a detailed status of the processing state, including current position and activity. Possible processing status messages on the **Current status** line are:
- Delaying – waiting for more data
- Suspended – waiting to be resumed
- Processing data – processing data
- Starting initial load – starting an initial load task
- Processing source tables – processing data for initial load task
- Reading from data source – reading from the data source, such as a source table or transaction log
- Adding record to transaction list – adding a record to the file memory transaction list
- At EOF (end of file) – no more records to process

In addition to the preceding statuses, the following status notations appear during an Extract recovery after an abend event. You can follow the progress as Extract continually changes its log read position over the course of the recovery.

- In recovery[1] – Extract is recovering to its checkpoint in the transaction log.
- In recovery[2] – Extract is recovering from its checkpoint to the end of the trail.
- Recovery complete – The recovery is finished, and normal processing will resume.

STOP
Stops Extract. If there are any long-running transactions (based on the WarnLongTrans parameter), the following message will be displayed:

Sending STOP request to EXTRACT JC108XT...
There are open, long-running transactions. Before you stop Extract, make the archives containing data for those transactions available for when Extract restarts. To force Extract to stop, use the SEND EXTRACT group, FORCESTOP command.
Oldest redo log file necessary to restart Extract is:
Redo Thread 1, Redo Log Sequence Number 150, SCN 31248005, RBA 2912272.

TRACE[2] {file_name | OFF}
Turns tracing on and off. Tracing captures information to the specified file to reveal processing bottlenecks. Contact Oracle Support for assistance if the trace reveals significant processing bottlenecks.

TRACE
Captures step-by-step processing information.

TRACE2
Identifies code segments rather than specific steps.

file_name
Specifies the name of the file to which the trace information is written. If a trace is already running when SEND EXTRACT is issued with TRACE, the existing trace file is closed and the trace is resumed to the new file specified with file_name.

OFF
Turns off tracing.

TRACE OFF file_name
Turns tracing off only for the specified trace file.
TRACEINIT
Resets tracing statistics back to 0 and then starts accumulating statistics again. Use this option to track the current behavior of processing, as opposed to historical.

TRANLOGOPTIONS {PREPAREFORUPGRADETOIE | NOPREPAREFORUPGRADETOIE}
(Oracle) Valid when upgrading from Classic to Integrated Extract on Oracle RAC.

When upgrading on Oracle RAC from Classic to Integrated Extract, you must set the PREPAREFORUPGRADETOIE option before stopping Classic Extract for the upgrade then wait for the information message in the report file that indicates that the parameter has taken effect before proceeding with the upgrade. For detailed upgrade instructions, see Upgrading Oracle GoldenGate for Windows and UNIX.

PREPAREFORUPGRADETOIE
Set PREPAREFORUPGRADETOIE in the Extract parameter file, which requires a restart of Extract, or you can set it dynamically for a running extract from GGSCI using this command:

SEND EXTRACT extract_name TRANLOGOPTIONS PREPAREFORUPGRADETOIE

NOPREPAREFORUPGRADETOIE
Dynamically turns off the PREPAREFORUPGRADETOIE option if necessary. The default is NOPREPAREFORUPGRADETOIE.

TRANLOGOPTIONS (PURGEORPHANEDTRANSACTIONS | NOPURGEORPHANEDTRANSACTIONS)
Valid for Oracle RAC. Enables or disables purging of orphaned transactions that occur when a node fails and Extract cannot capture the rollback. See "TRANLOGOPTIONS" on page 3-364 for descriptions.

TRANLOGOPTIONS TRANSCLEANUPFREQUENCY minutes
Valid for Oracle RAC. Specifies the interval, in minutes, after which Oracle GoldenGate scans for orphaned transactions and then re-scans to confirm and delete them. Valid values are from 1 to 43200 minutes. Default is 10 minutes. See "TRANLOGOPTIONS" on page 3-364.

VAMMESSAGE 'Teradata_command'
VAMMESSAGE { 'ARSTATS' | 'INCLUDELIST [filter]' | 'EXCLUDELIST [filter]' } VAMMESSAGE 'OPENTRANS'
Sends a command to the capture API that is used by Extract.

A Teradata command can be any of the following:

'control:terminate'
Stops a replication group. Required before dropping or altering a replication group in Teradata.

'control:suspend'
Suspends a replication group. Can be used when upgrading Oracle GoldenGate.

'control:resume'
Resumes a replication group after it has been suspended.

'control:copy database.table'
Copies a table from the source database to the target database.

A SQL/MX command can be any of the following. The module returns a response to GGSCI. The response can be either ERROR or OK along with a response message.
'ARSTATS'
Displays TMF audit reading statistics.

'FILELIST [filter]'
Displays the list of tables for which Extract has encountered data records in the audit trail that match the selection criteria in the TABLE parameters. The filter option allows use of a wildcard pattern to filter the list of tables returned. GETFILELIST can also be used in the same manner.

'EXCLUDELIST [filter]'
Displays the list of tables for which Extract has encountered data records in the audit trail that do not match the selection criteria in the TABLE parameters. The filter option allows use of a wildcard pattern to filter the list of tables returned. Certain system tables that are implicitly excluded will always be present in the list of excluded tables.

A SQL Server command can be the following:

'OPENTRANS'
Prints a list of open transactions with their transaction ID, start time, first LSN, and the number of operations they contain.

Examples

Example 1
SEND EXTRACT finance, ROLLOVER

Example 2
SEND EXTRACT finance, STOP

Example 3
SEND EXTRACT finance, VAMMESSAGE 'control:suspend'

Example 4
SEND EXTRACT finance, TRANLOGOPTIONS TRANSCLEANUPFREQUENCY 20

Example 5
This example explains SKIPTRANS. Start with the following SHOWCH output, which shows that thread 2 is at Read Checkpoint #3. See Administering Oracle GoldenGate for Windows and UNIX for more information about checkpoints.

INFO extract SHOWCH
Read Checkpoint #3
Oracle RAC Redo Log
Startup Checkpoint (starting position in the data source):
Thread #: 2
Sequence #: 17560
RBA: 65070096
Timestamp: 2011-07-30 20:04:47.000000
SCN: 1461.3499051750 (6278446271206)
Redo File: RAC4REDO/sss11g/onlinelog/group_4.292.716481937

Therefore, SKIPTRANS should be: SKIPTRANS xid THREAD 3.
Example 6
SEND EXTRACT finance, SHOWTRANS COUNT 2

Example 7
The following shows the default output of SHOWTRANS.

Oldest redo log file necessary to restart Extract is:
Redo Thread 1, Redo Log Sequence Number 148, SCN 30816254, RBA 17319664

<table>
<thead>
<tr>
<th>XID</th>
<th>Items</th>
<th>Extract</th>
<th>Redo Thread</th>
<th>Start Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.15.52582</td>
<td>30000</td>
<td>JC108XT</td>
<td>1</td>
<td>2011-01-18:12:51:27</td>
</tr>
</tbody>
</table>

Status: Running

Example 8
The following shows SHOWTRANS output with TABULAR in effect (view is truncated on right)

Dumping transaction memory at 2011-01-21 13:36:54.
Record #1:
Header (140 bytes):
Data (93 bytes):

1-46 Reference for Oracle GoldenGate for Windows and UNIX
When analyzing the summary output of `SHOWTRANS`, understand that it shows all currently running transactions on the database (as many as will fit into a predefined buffer). Extract must track every open transaction, not just those that contain operations on tables configured for Oracle GoldenGate, because it is not known whether operations on configured tables will be added to a transaction at some point in the future.

The `Items` field of the `SHOWTRANS` output shows the number of operations in the transaction that have been captured by Oracle GoldenGate so far, not the total number of operations in the transaction. If none of the operations are for configured tables, or if only some of them are, then `Items` could be 0 or any value less than the total number of operations.

The `Start Time` field shows the timestamp of the first operation that Oracle GoldenGate extracts from a transaction, not the actual start time of the transaction itself.

---

**Note:** Command output may vary somewhat from the examples shown due ongoing enhancements of the Oracle GoldenGate software.
Use `START EXTRACT` to start the Extract process. To confirm that Extract has started, use the `INFO EXTRACT` or `STATUS EXTRACT` command. Extract can be started at its normal start point (from initial or current checkpoints) or from an alternate, user-specified position in the data source.

**Normal Start Point**
Without options, `START EXTRACT` directs a primary Extract and a data pump Extract to start processing at one of the following locations in the data source to maintain data integrity:

- After graceful or abnormal termination: At the first unprocessed transaction in the data source from the previous run, as represented by the current read checkpoint.
- First-time startup after the group was created: At the start point specified with the `ADD EXTRACT` command.

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints.

Extract also can be started from the command line of the operating system for certain synchronization configurations. For more information on the proper configuration and startup method to use for your purposes, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Alternate Start Point**
The `ATCSN` and `AFTERCSN` options enable you to establish a logical starting point for a primary Extract or a data pump, after you establish an approximate physical starting point with the `ADD EXTRACT` or `ALTER EXTRACT` command. For example, in an initial-load scenario, after a backup is applied to the target, the serial identifier of the last transaction (such as an Oracle SCN) can be mapped to an Oracle GoldenGate CSN (*commit sequence number*) value, which can be used to start Extract with the `AFTERCSN` option. By starting with the first transaction after the specified CSN, Extract omits the transactions that were included in the backup, which would otherwise cause duplicate-record and missing-record errors.

Before starting Extract with `ATCSN` or `AFTERCSN`, you must establish a physical starting location with one of the following commands:

- `ADD EXTRACT` with the `BEGIN` option set to a timestamp that is earlier than the CSN value specified with `ATCSN` or `AFTERCSN`. The transaction log that contains the timestamp and every log thereafter must be available on the system before Extract is started.
- `ALTER EXTRACT` to the sequence number of the log that contains the CSN specified with `ATCSN` or `AFTERCSN`.

**Note:** See *Administering Oracle GoldenGate for Windows and UNIX* for more information about the values that comprise a CSN for a given database.

**Syntax**

```
START EXTRACT group_name [ATCSN csn | AFTERCSN csn]
```
**group_name**
The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* starts all Extract groups whose names begin with T.

**ATCSN csn | AFTERCSN csn**
Specifies an alternate start point. (See “Alternate Start Point” for usage instructions.)

**ATCSN**
Directs Extract to position its start point at the first transaction that has the specified CSN. Any transactions in the data source that have CSN values less than the specified one are skipped.

**AFTERCSN**
Directs Extract to position its start point at the beginning of the first transaction after the one that has the specified CSN. Any transactions in the data source that have CSN values that are less than, or equal to, the specified one are skipped.

**csn**
Specifies a CSN value. Enter the CSN value in the format that is valid for the database. See *Administering Oracle GoldenGate for Windows and UNIX* for CSN formats and descriptions. Extract abends if the format is invalid and writes a message to the report file. To determine the CSN to supply after an initial load is complete, use the serial identifier at which the load utility completed. Otherwise, follow the instructions in the initial load procedure for determining when to start Extract.

The following are additional guidelines to observe when using **ATCSN** and **AFTERCSN**:

- To support starting at, or after, a CSN, the trail must be of Oracle GoldenGate version 10.0.0 or later, because the CSN is stored in the file header so that it is available to downstream processes.

- When a record that is specified with a CSN is found, Extract issues a checkpoint. The checkpoint ensures that subsequent Extract startups begin from the requested location, and not from a point prior to the requested CSN.

- You must establish a physical start point in the transaction log or trail for Extract with **ADD EXTRACT** or **ALTER EXTRACT** before using **ATCSN** or **AFTERCSN**. These options are intended to be an additional filter after Extract is positioned to a physical location in the data source.

### Examples

**Example 1**

```
START EXTRACT finance
```

**Example 2**

```
START EXTRACT finance ATCSN 684993
```

**Example 3**

```
START EXTRACT finance AFTERCSN 684993
```
Use **STATS EXTRACT** to display statistics for one or more Extract groups. The output includes DML and DDL operations that are included in the Oracle GoldenGate configuration.

To get the most accurate number of operations per second that are being processed, do the following.

1. Issue the **STATS EXTRACT** command with the **RESET** option.
2. Issue the **STATS EXTRACT REPORTRATE** command. The **LATEST STATISTICS** field shows the operations per second.

---

**Note:** The actual number of DML operations executed on a DB2 database might not match the number of extracted DML operations reported by Oracle GoldenGate. DB2 does not log update statements if they do not physically change a row, so Oracle GoldenGate cannot detect them or include them in statistics.

---

To get accurate statistics on a Teradata source system where Oracle GoldenGate is configured in maximum protection mode, issue **STATS EXTRACT** to the VAM-sort Extract, not the primary Extract. The primary Extract may contain statistics for uncommitted transactions that could be rolled back; whereas the VAM-sort Extract reports statistics only for committed transactions.

**Syntax**

```sql
STATS EXTRACT group_name
[,, statistic]
[,, TABLE [container. | catalog.]schema.table]
[,, TOTALONLY [container. | catalog.]schema.table]
[,, REPORTCHARCONV]
[,, REPORTFETCH | NOREPORTFETCH]
[,, REPORTDATES time_units]
[,, ... ]
```

**group_name**
The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* returns statistics for all Extract groups whose names start with T.

**statistic**
The statistic to be displayed. More than one statistic can be specified by separating each with a comma, for example **STATS EXTRACT finance, TOTAL, DAILY**.

Valid values:

- **TOTAL**
  Displays totals since process startup.

- **DAILY**
  Displays totals since the start of the current day.

- **HOURLY**
  Displays totals since the start of the current hour.
LATEST
Displays totals since the last RESET command.

RESET
Resets the counters in the LATEST statistical field.

TABLE [container. | catalog.]schema.table
Displays statistics only for the specified table or a group of tables specified with a wildcard (*). The table name or wildcard specification must be fully qualified with the two-part or three-part name, for example hr.emp or *.*.*.

TOTALSONLY [container. | catalog.]schema.table
Summarizes the statistics for the specified table or a group of tables specified with a wildcard (*). The table name or wildcard specification must be fully qualified with the two-part or three-part name, for example hr.emp or *.*.*.

REPORTCHARCONV
Use only when TABLE parameters have a TARGET clause and character-set conversion is performed. The following statistics are added to the STATS output:

Total column character set conversion failure: the number of validation or conversion failures in the current Extract run.

Total column data truncation: the number of times that column data was truncated in the current Extract run as the result of character set conversion

REPORTFETCH | NOREPORTFETCH
Controls whether or not statistics about fetch operations are included in the output. The default is NOREPORTFETCH. See "STATOPTIONS" on page 3-301 for defaults that control fetching and options for altering fetch behavior. The output of REPORTFETCH is as follows:

- row fetch attempts: The number of times Extract attempted to fetch a column value from the database when it could not obtain the value from the transaction log.
- fetch failed: The number of row fetch attempts that failed.
- row fetch by key: Valid for Oracle. The number of row fetch attempts that were made by using the primary key. The default is to fetch by row ID.

REPORTRATE time_units
Displays statistics in terms of processing rate rather than absolute values.

Valid values:

HR
MIN
SEC

Example

Example 1
The following example displays total and hourly statistics per minute for a specific table, and it also resets the latest statistics and outputs fetch statistics.

STATS EXTRACT finance, TOTAL, HOURLY, TABLE hr.acct,
REPORTRATE MIN, RESET, REPORTFETCH
Example 2

The following is sample output using the LATEST and REPORTFETCH options

STATS EXTRACT ext, LATEST, REPORTFETCH
Sending STATS request to EXTRACT GGSEXT...
Start of Statistics at 2011-01-08 11:45:05.
DDL replication statistics (for all trails):
*** Total statistics since extract started ***
  Operations                        3.00
  Mapped operations                 3.00
  Unmapped operations               0.00
  Default operations                0.00
  Excluded operations               0.00
Output to ./dirdat/aa:
Extracting from HR.EMPLOYEES to HR.EMPLOYEES:
*** Latest statistics since 2011-01-08 11:36:55 ***
  Total inserts                     176.00
  Total updates                     0.00
  Total deletes                     40.00
  Total discards                    0.00
  Total operations                  216.00
Extracting from HR.DEPARTMENTS to HR.DEPARTMENTS:
*** Latest statistics since 2011-01-08 11:36:55 ***
No database operations have been performed.
End of Statistics.
STATUS EXTRACT

Use STATUS EXTRACT to determine whether or not Extract is running. A status of RUNNING can mean one of the following:

- **Active**: Running and processing (or able to process) data. This is the normal state of a process after it is started.
- **Suspended**: The process is running, but suspended due to an \texttt{EVENTACTIONS SUSPEND} action. In a suspended state, the process is not active, and no data can be processed, but the state of the current run is preserved and can be continued by issuing the \texttt{RESUME} command in GGSCI. The RBA in the \texttt{INFO} command reflects the last checkpointed position before the suspend action. To determine whether the state is active or suspended, issue the \texttt{SEND EXTRACT} command with the \texttt{STATUS} option.

Syntax

```
STATUS EXTRACT group_name [ , TASKS | ALLPROCESSES] [UPGRADE | DOWNGRADE]
```

\texttt{group_name}

The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* returns status for all Extract groups whose names begin with T.

\texttt{TASKS}

Displays status only for Extract tasks. By default, tasks are not displayed unless you specify a single Extract group (without wildcards).

\texttt{ALLPROCESSES}

Displays status for all Extract groups, including tasks.

\texttt{UPGRADE} | \texttt{DOWNGRADE}

Valid for an Oracle database only. If Extract cannot be upgraded or downgraded, the reason why is displayed. A wildcarded Extract name is not allowed with this option. Before using this command, issue the \texttt{DBLOGIN} command.

\texttt{UPGRADE}

Displays whether the Extract can be upgraded from classic capture mode to integrated capture mode.

\texttt{DOWNGRADE}

Displays whether the Extract can be downgraded from integrated capture mode to classic capture mode.

Examples

**Example 1**

```
STATUS EXTRACT finance
```

**Example 2**

```
STATUS EXTRACT fin*
```
STOP EXTRACT

Use STOP EXTRACT to stop Extract gracefully. The command preserves the state of synchronization for the next time Extract starts, and it ensures that Manager does not automatically start Extract.

If there are open, long-running transactions when you issue STOP EXTRACT, you might be advised of the oldest transaction log file that will be needed for that transaction when Extract is restarted. You can use the SEND EXTRACT option of SHOWTRANS to view details and data of those transactions and then, if desired, use the SKIPTRANS or FORCETRANS options to skip the transaction or force it to be written as a committed transaction to the trail. See “SEND EXTRACT” on page 1-37.

Syntax

```
STOP EXTRACT group_name
```

**group_name**
The name of an Extract group or a wildcard (*) to specify multiple groups. For example, T* stops all Extract processes for groups whose names begin with T.

```
STOP EXTRACT finance
```
UNREGISTER EXTRACT

Use UNREGISTER EXTRACT to remove the registration of an Extract group from an Oracle database. UNREGISTER EXTRACT is valid only for a primary Extract group. Do not use it for a data pump Extract.

To register an Extract group with the database, use the REGISTER EXTRACT command.

To upgrade an Extract from classic capture mode to integrated capture mode, use the ALTER EXTRACT command.

See Installing and Configuring Oracle GoldenGate for Oracle Database for more information about configuring and registering Oracle GoldenGate for an Oracle database.

Syntax

UNREGISTER EXTRACT group_name
   {DATABASE  | LOGRETENTION}

(group_name)
The name of the Extract group that is to be unregistered from the database. Do not use a wildcard. This group must currently be registered with the database.

DATABASE
Disables integrated capture mode for the Extract group.

This command removes the database capture (mining) server that has the same name as the Extract group. For additional information about support for, and configuration of, the Extract capture modes, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Before using UNREGISTER EXTRACT with DATABASE, do the following:

1. Stop Extract with the STOP EXTRACT command.
2. Log in to the mining database with the DBLOGIN or MININGDBLOGIN command with the privileges granted in the dbms_goldengate_auth.grant_admin_privilege procedure. For local capture, DBLOGIN is required. For downstream capture, DBLOGIN and MININGDBLOGIN are both required.
3. Delete the Extract group with DELETE EXTRACT.

LOGRETENTION
Disables log retention for the specified Extract group and removes the underlying Oracle Streams capture process. Use UNREGISTER EXTRACT with LOGRETENTION only if you no longer want to capture changes with this Extract group. The log-retention feature is controlled with the LOGRETENTION option of the TRANLOGOPTIONS parameter.

Before using UNREGISTER EXTRACT with LOGRETENTION, stop Extract with the STOP EXTRACT command. Next, issue the DBLOGIN command with the privileges shown in 1–2.

Examples

Example 1
UNREGISTER EXTRACT sales LOGRETENTION
Example 2

UNREGISTER EXTRACT sales DATABASE
ADD REPLICAT

Use ADD REPLICAT to create a Replicat group. Unless SPECIALRUN is specified, ADD REPLICAT creates an online process group that creates checkpoints so that processing continuity is maintained from run to run.

This command cannot exceed 500 bytes in size for all keywords and input, including any text that you enter for the DESC option.

Oracle GoldenGate supports up to 5,000 concurrent Extract and Replicat groups per instance of Oracle GoldenGate Manager. At the supported level, all groups can be controlled and viewed in full with GGSCI commands such as the INFO and STATUS commands. Oracle GoldenGate recommends keeping the number of Extract and Replicat groups (combined) at the default level of 300 or below in order to manage your environment effectively.

(Oracle) Unless the INTEGRATED option is used, this command creates a Replicat group in non-integrated mode. For more information about Replicat modes, see "Deciding Which Apply Method to Use" in Installing and Configuring Oracle GoldenGate for Oracle Database and “BATCHSQL” on page 3-26.

Syntax

ADD REPLICAT group_name
[. INTEGRATED | COORDINATED [MAXTHREADS number]]
[. SPECIALRUN |
  , EXTFILE file_name |
  , EXTRAIL trail_name]
[. BEGIN {NOW | yyyy-mm-dd hh:mm:ss[.cccccc]} | |
  , EXTSEQNO sequence_number, EXTRBA rba]
[. CHECKPOINTTABLE owner.table | NODBCHECKPOINT]
[. PARAMS file_name]
[. REPORT file_name]
[. DESC 'description']
[. CPU number]
[. PRI number]
[. HOMETERM device_name]
[. PROCESSNAME process_name]

**group_name**
The name of the Replicat group. The name of a coordinated Replicat group can contain a maximum of five characters. The name of a regular Replicat group can contain up to eight characters. See Administering Oracle GoldenGate for Windows and UNIX for more information about naming conventions for process groups.

**INTEGRATED**
(Oracle) Creates the Replicat in integrated mode. Without this option, ADD REPLICAT creates the Replicat in non-integrated (classic) mode. In this mode, the Replicat process leverages the apply processing functionality that is available within the Oracle database. In this mode, Replicat operates as follows:

- Reads the Oracle GoldenGate trail.
- Performs data filtering, mapping, and conversion.
- Constructs logical change records (LCR) that represent source database DML or DDL transactions (in committed order).
- Attaches to a background process in the target database known as a database inbound server by means of a lightweight streaming interface.

- Transmits the LCRs to the inbound server, which applies the data to the target database.

Do not use INTEGRATED with the SPECIALRUN or EXTFILE options. INTEGRATED must be used for an online change-synchronization Replicat that reads from a local EXTTRAIL-specified trail.

Integrated Replicat does not require a checkpoint table (ADD CHECKPOINTTABLE command and CHECKPOINTTABLE parameter) or a trace table (TRACETABLE parameter). Integrated Replicat does not maintain either of these tables.

When in integrated mode, Replicat does not support the following parameters:

- BULKLOAD (Do not use integrated Replicat as an initial-load Replicat.)
- SPECIALRUN
- GENLOADFILES
- SHOWSYNTAX
- MAXTRANSOPS (is ignored)

See Installing and Configuring Oracle GoldenGate for Oracle Database for more information about configuring and using integrated Replicat.

COORDINATED [MAXTHREADS number]

Creates the Replicat in coordinated mode. A coordinated Replicat is multithreaded to enable parallel processing. This option adds the coordinator (identified by the group name itself) and the maximum number of processing threads that are specified by default or with MAXTHREADS. Dependencies are computed and coordinated by the coordinator, and the SQL processing is performed by the threads.

Do not use COORDINATED with the SPECIALRUN or EXTFILE options. COORDINATED must be used for an online change-synchronization Replicat that reads from a local EXTTRAIL-specified trail. For more information about coordinated Replicat, see Administering Oracle GoldenGate for Windows and UNIX.

**Note:** Note that the group name of a coordinated Replicat can contain only five characters. See Administering Oracle GoldenGate for Windows and UNIX for more information about naming conventions for process groups.

**MAXTHREADS number**

Specifies the maximum number of processing threads that this Replicat group can spawn. These threads are all created on startup, but depending on what is specified in the MAP statements in the parameter file, some or all of these threads will process the workload at any given time. As a general rule, specify twice the number of threads that you specify in the MAP statements when you partition the workload. This allows you to add threads in the event that the workload increases, without having to drop and recreate the Replicat group.

See TABLE | MAP for more information about how to partition the workload across threads.

The default number of threads is 25 if MAXTHREADS is omitted. The maximum number of threads is 500.
MAXTHREADS has a relationship to the MAXGROUPS parameter. MAXGROUPS controls the maximum number of process groups (Extract and Replicat) allowed per instance of Oracle GoldenGate. Each Replicat thread is considered a Replicat group in the context of MAXGROUPS. Therefore, the number of Extract and Replicat groups in the Oracle GoldenGate instance, plus the value of MAXTHREADS, cannot exceed the value of MAXGROUPS. For more information, see MAXGROUPS.

**SPECIALRUN**
Creates a Replicat special run as a task. Either SPECIALRUN, EXTFILE, or EXTTRAIL is required. When Extract is in SPECIALRUN mode, do not start Replicat with the START REPLICAT command in GGSCI. Do not use this option with the INTEGRATED or COORDINATED option.

**EXTFILE file_name**
Specifies the relative or fully qualified name of an extract file that is specified with RMTFILE in the Extract parameter file. Do not use this option with the INTEGRATED option.

**EXTTRAIL trail_name**
Specifies the relative or fully qualified name of a trail that was created with the ADD RMTTRAIL or ADD EXTTRAIL command.

**BEGIN {NOW | yyyy-mm-dd[ hh:mm[:ss[.cccccc]]]}**
Defines an initial checkpoint in the trail. See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints.

**NOW**
Begins replicating changes from the time when the group is created.

**yyyy-mm-dd[ hh:mm[:ss[.cccccc]]]**
Begins extracting changes from a specific time.

**EXTSEQNO sequence_number**
Specifies the sequence number of the file in a trail in which to begin processing data. Specify the sequence number, but not any zeroes used for padding. For example, if the trail file is c:\ggs\dirdat\aa000026, you would specify EXTSEQNO 26.

By default, processing begins at the beginning of a trail unless this option is used. To use EXTSEQNO, you must also use EXTRBA. Contact Oracle Support before using this option.

**EXTRBA rba**
Specifies the relative byte address within the trail file that is specified by EXTSEQNO. Contact Oracle Support before using this option.

**CHECKPOINTTABLE owner.table**
Specifies that this Replicat group will write checkpoints to the specified table in the database. Include the owner and table name, as in hr.hr_checkpoint. This argument overrides any default CHECKPOINTTABLE specification in the GLOBALS file. The table must first be added with the ADD CHECKPOINTTABLE command. Do not use this option with the INTEGRATED option.

**NODBCHECKPOINT**
Specifies that this Replicat group will not write checkpoints to a checkpoint table. This argument overrides any default CHECKPOINTTABLE specification in the GLOBALS file. This argument is required if you do not want to use a checkpoint table with the
Replicat group that is being created. Do not use this option with the INTEGRATED option.

**PARAMS file_name**
Specifies a parameter file in a location other than the default of dirprm within the Oracle GoldenGate directory. Specify the fully qualified path name.

**REPORT file_name**
Specifies the full path name of a process report file in a location other than the default of dirrpt within the Oracle GoldenGate directory.

**DESC 'description'**
Specifies a description of the group, such as 'Loads account_tab on Serv2'. Enclose the description within quotes. You can use either the abbreviated keyword DESC or the full word DESCRIPTION.

**CPU number**
Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1 - 15 and -1 is default, which is assigned 1 higher than the last Manager started.

**PRI number**
Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers are 1 - 199 and -1 is the default, and is the same as the manager process priority.

**HOMETERM device_name**
Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/xxxxxx form. The default is $zhome or the current session HOMETERM when $zhome is not defined.

**PROCESSNAME process_name**
Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/xxxxxx form. The default is a system generated process name.

### Examples

**Example 1**
ADD REPLICAT sales, EXTRAIL dirdat/rt

**Example 2**
ADD REPLICAT sales, INTEGRATED, EXTRAIL dirdat/rt

**Example 3**
This example creates Replicat in coordinated mode. It indicates that up to 100 threads can be employed in parallel at any given point in processing.

ADD REPLICAT sales, COORDINATED MAXTHREADS 100, EXTRAIL dirdat/rt

**Example 4**
This example creates Replicat on a SQL/MX platform.

ADD REPLICAT reptcp, CPU 2, PRI 148, HOMETERM $ZTN0.#P79BP32, PROCESSNAME $repl
**ALTER REPLICAT**

Use **ALTER REPLICAT** to change the attributes of a Replicat group that was created with the **ADD REPLICAT** command. Before using this command, stop Replicat by issuing the **STOP REPLICAT** command. If this is a coordinated Replicat group, the **ALTER** takes effect for all threads unless the **threadID** option is used.

**Note:** **ALTER REPLICAT** does not support switching from regular Replicat mode to coordinated mode. You must stop processes, make certain all of the en route data is applied to the target, roll the trail to a new trail, drop and recreate the Replicat group in coordinated mode, and then start the processes again.

**Syntax**

```sql
ALTER REPLICAT group_name[threadID], { 
  ADD REPLICAT option [, ...] | 
  INTEGRATED | NONINTEGRATED, CHECKPOINTTABLE owner.table 
} [, CPU number] 
[, PRI number] 
[, HOMETERM device_name] 
[, PROCESSNAME process_name]
```

**group_name[threadID]**
The name of the Replicat group or a thread of a coordinated Replicat that is to be altered. To specify a thread, use the full thread name, such as **ALTER REPLICAT fin003, EXTSEQNO 53**. If a thread ID is not specified, the **ALTER** takes effect for all threads of the Replicat group.

**ADD REPLICAT option**
An **ADD REPLICAT** option. For a non-integrated Replicat, you can change the description or any service option that was configured with the **ADD REPLICAT** command, except for the **CHECKPOINT** and **NODBCHECKPOINT** options.

**INTEGRATED**
Switches Replicat from non-integrated mode to integrated mode. Transactions currently in process are applied before the switch is made. See *Administering Oracle GoldenGate for Windows and UNIX* for the full procedure for performing the transition from non-integrated to integrated Replicat.

**NONINTEGRATED, CHECKPOINTTABLE owner.table**
(Oracle) Switches Replicat from integrated mode to non-integrated mode.

For **CHECKPOINTTABLE**, specify the owner and name of a checkpoint table. This table must be created with the **ADD CHECKPOINTTABLE** command before issuing **ALTER EXTRACT** with **NONINTEGRATED**.

See *Administering Oracle GoldenGate for Windows and UNIX* for the full procedure for performing the transition from integrated Replicat to non-integrated Replicat.

See *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about integrated Replicat.
CPU number
Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1 - 15 and -1 is default, which is assigned 1 higher than the last Manager started.

PRI number
Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers are 1 - 199 and -1 is the default, and is the same as the manager process priority.

HOMETERM device_name
Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/xxxxx form. The default is $zhome or the current session HOMETERM when $zhome is not defined.

PROCESSNAME process_name
Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/xxxxx form. The default is a system generated process name.

Examples

Example 1
ALTER REPLICAT finance, EXTSEQNO 53

Example 2
ALTER REPLICAT finance, EXTRBA 0

Example 3
ALTER REPLICAT finance, BEGIN 2011-01-07 08:00:00

Example 4
ALTER REPLICAT finance, INTEGRATED

Example 5
ALTER REPLICAT finance, NONINTEGRATED, CHECKPOINTTABLE ogg.checkpt

Example 6
ALTER REPLICAT fin001, EXTSEQNO 53

Example 7
The following alters a Replicat on a SQL/MX NonStop platform.

ALTER REPLICAT reptcp, CPU 3, PRI 150, HOMETERM /G/zhome, PROCESSNAME default
CLEANUP REPLICAT

Use CLEANUP REPLICAT to delete run history for a specified Replicat group. The cleanup keeps the last run record intact so that Replicat can resume processing from where it left off.

Before using this command, stop Replicat by issuing the STOP REPLICAT command.

**Syntax**

CLEANUP REPLICAT group_name[threadID] [, SAVE count]

*group_name[threadID]*

One of the following:

- *group_name*: The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* cleans up all Replicat groups whose names begin with T. If the specified group (or groups) is a coordinated Replicat, the cleanup applies to all threads.

- *group_name[threadID]*: A thread of a coordinated Replicat, identified by its full name (group name plus threadID), such as finance003.

*SAVE count*

Excludes the specified number of the most recent records from the cleanup.

**Examples**

**Example 1**
The following deletes all but the last record.

CLEANUP REPLICAT finance

**Example 2**
The following deletes all but the most recent five records.

CLEANUP REPLICAT *, SAVE 5

**Example 3**
The following deletes all but the most recent five records for thread 3 of coordinated Replicat group fin.

CLEANUP REPLICAT fin003, SAVE 5
DELETE REPLICAT

Use DELETE REPLICAT to delete a Replicat group. This command deletes the checkpoint file but leaves the parameter file intact. Then you can re-create the group or delete the parameter file as needed. This command frees up trail files for purging by Manager, because the checkpoints used by the deleted group are removed (assuming no other processes are reading the file).

Before using DELETE REPLICAT, stop Replicat with the STOP REPLICAT command.

If this is an integrated Replicat (Oracle only) or a non-integrated Replicat that uses a checkpoint table, do the following after you stop Replicat:

1. Log into the database by using the DBLOGIN command. DBLOGIN enables DELETE REPLICAT to delete the checkpoints from the checkpoint table of a non-integrated Replicat or to delete the inbound server that an integrated Replicat uses. For more information, see "DBLOGIN" on page 1-116.

2. Issue DELETE REPLICAT.

Syntax

DELETE REPLICAT group_name [!]

`group_name`
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* deletes all Replicat groups whose names begin with T.

`!`
Use this option to force the Replicat group to be deleted if the DBLOGIN command is not issued before the DELETE REPLICAT command is issued. If the group is a nonintegrated Replicat, this option deletes the group’s checkpoints from the checkpoint file on disk, but not from the checkpoint table in the database. If using this option to delete an integrated Replicat group, you must use the UNREGISTER REPLICAT command to delete the inbound server from the target database. This option can also be used to ignore the prompt that occurs when a wildcard specifies multiple groups.

---

**Note:** The basic DELETE REPLICAT command commits an existing Replicat transaction, but the `!` option prevents the commit.

---

Example

DELETE REPLICAT finance
INFO REPLICAT

Use **INFO REPLICAT** to retrieve the processing history of a Replicat group. The output of this command includes:

- The status of Replicat (**STARTING**, **RUNNING**, **STOPPED** or **ABENDED**). **STARTING** means that the process has started but has not yet locked the checkpoint file for processing.
- (Oracle database) The Replicat mode: non-integrated or integrated.
- Whether or not Replicat is in coordinated mode and, if so, how many threads it currently uses.
- Approximate Replicat lag.
- The trail from which Replicat is reading.
- Replicat run history, including checkpoints in the trail.
- Information about the Replicat environment.

The basic command displays information only for online (continuous) Replicat groups. Tasks are excluded.

Replicat can be stopped or running when **INFO REPLICAT** is issued. In the case of a running process, the status of **RUNNING** can mean one of the following:

- **Active**: Running and processing (or able to process) data. This is the normal state of a process after it is started.
- **Suspended**: The process is running, but suspended due to an `EVENTACTIONS SUSPEND` action. In a suspended state, the process is not active, and no data can be processed, but the state of the current run is preserved and can be continued by issuing the `RESUME` command in GGSCI. The RBA in the **INFO** command reflects the last checkpointed position before the suspend action. To determine whether the state is active or suspended, issue the `SEND REPLICAT` command with the **STATUS** option.

**About lag**

Checkpoint Lag is the lag, in seconds, at the time the last checkpoint was written to the trail. For example, consider the following example.

- Current time = 15:00:00
- Last checkpoint = 14:59:00
- Timestamp of the last record processed = 14:58:00

Assuming these values, the lag is reported as 00:01:00 (one minute, the difference between 14:58 and 14:59).

A lag value of **UNKNOWN** indicates that Replicat could be running but has not yet processed records, or that the source system’s clock is ahead of the target system’s clock (due to clock imperfections, not time zone differences). For more precise lag information, use **LAG REPLICAT** (see "LAG REPLICAT" on page 1-70).

**Syntax**

```
INFO REPLICAT [group_name[|threadID]]
[ , DETAIL]
[ , SHOWCH [n]]
```
INFO REPLICAT

[ TASKS | ALLPROCESSES ]

group_name[threadID]
The name of:

- A Replicat group or a wildcard (*) to specify multiple groups. For example, T* shows information for all Replicat groups whose names begin with T.
- A thread of a coordinated Replicat, identified by its full name. For example, fin003 shows information only for thread 3 of the fin group.

DETAIL
Displays detail information. For an Oracle target, DETAIL displays the name of the inbound server when Replicat is in integrated mode. See Example 4.

To view LOGBSN information with the DETAIL output, issue the DBLOGIN command before you issue INFO REPLICAT. If the command is issued for a specific thread ID of a coordinated Replicat, only the LOGBSN for that thread is displayed. Otherwise, the LOGBSNs for all threads are displayed. For more information about recovering Extract by using the LOGBSN, see Administering Oracle GoldenGate for Windows and UNIX.

If Replicat is in coordinated mode, DETAIL will display only the active threads. For example, if a Replicat named CR was created with a maximum of 15 threads, but only threads 7-9 are running, INFO REPLICAT group_name with DETAIL will show only the coordinator thread (CR), CR007, CR008, and CR009. Checkpoints will exist for the other threads, but they will not be shown in the command output. See the examples for sample output.

SHOWCH [n]
Displays current checkpoint details, including those recorded to the checkpoint file and those recorded to the checkpoint table, if one is being used. The database checkpoint display includes the table name, the hash key (unique identifier), and the create timestamp.

Specify a value for n to include the specified number of previous checkpoints as well as the current one.

See Administering Oracle GoldenGate for Windows and UNIX for more information about checkpoints.

TASKS
Displays only Replicat tasks. Tasks that were specified by a wildcard argument are not displayed by INFO REPLICAT.

ALLPROCESSES
Displays all Replicat groups, including tasks.

Examples

Example 1
INFO REPLICAT *, DETAIL, ALLPROCESSES

Example 2
INFO REPLICAT *, TASKS

Example 3
INFO REPLICAT fin003, SHOWCH
Example 4
The following shows sample output of INFO REPLICAT with DETAIL.

```

KILL REPLICAT

Use KILL REPLICAT to kill a Replicat process. Killing a process leaves the most recent checkpoint in place, and the current transaction is rolled back by the database, guaranteeing that no data is lost when the process is restarted. The Manager process will not attempt to restart a killed Replicat process. Use this command only if Replicat cannot be stopped gracefully with the STOP REPLICAT command.

Syntax

KILL REPLICAT group_name

*group_name*
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* kills all Replicat processes whose group names begin with T.

Example

KILL REPLICAT finance
LAG REPLICAT

Use LAG REPLICAT to determine a true lag time between Replicat and the trail. LAG REPLICAT estimates the lag time more precisely than INFO REPLICAT because it communicates with Replicat directly rather than reading a checkpoint position.

For Replicat, lag is the difference, in seconds, between the time that the last record was processed by Replicat (based on the system clock) and the timestamp of the record in the trail.

Syntax

LAG REPLICAT group_name[threadID]

Group_name[threadID]
The name of:

- A Replicat group or a wildcard (*) to specify multiple groups. For example, T* shows lag for all Replicat groups whose names begin with T.
- A thread of a coordinated Replicat, identified by its full name. For example, fin003 shows lag for thread 3 of coordinated Replicat fin.

Examples

Example 1
LAG REPLICAT *

Example 2
LAG REPLICAT *fin*
REGISTER REPLICAT

Use the REGISTER REPLICAT command to register a Replicat group with a target Oracle database to support integrated Replicat mode. This command should not be necessary under normal Replicat conditions. The startup registers Replicat with the target database automatically. Use this command only if Oracle GoldenGate returns a message that an integrated Replicat is not registered with the database.

Before issuing this command, issue the DBLOGIN command as the Replicat database user with privileges granted through dbms_goldengate_auth.grant_admin_privilege.

For more information about integrated Replicat, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Syntax

REGISTER REPLICAT group_name DATABASE

*group_name*

The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* registers all Replicat groups whose names begin with T.

DATABASE

Required keyword to register with the target database. Creates a database inbound server and associates it with the specified Replicat group.

Example

REGISTER REPLICAT sales DATABASE
Send Replicat

Use SEND REPLICAT to communicate with a starting or running Replicat process. The request is processed as soon as Replicat is ready to accept commands from users.

Syntax

SEND REPLICAT group_name[threadID],

GROUP_NAME[THREAD_ID]

The name of the Replicat group or the name of a specific thread of a coordinated Replicat, for example fin003. If the command is issued for a specific thread, then an option that is used applies only to that thread. As an alternative, you can issue SEND REPLICAT with the THREADS option instead of including threadID with the group name.

If Replicat is not running, an error is returned.

CACHEMGR {CACHESTATS | CACHEQUEUES | CACHEPOOL n}

Returns statistics about the Oracle GoldenGate memory cache manager. CACHEMGR should only be used as explicitly directed by Oracle Support.

CACHESTATS

Returns statistics for virtual memory usage and file caching.

CACHEQUEUES

Returns statistics for the free queues only.

CACHEPOOL n

Returns statistics for the specified object pool only.

FORCESTOP

Forces Replicat to stop, bypassing any notifications. This command will roll back any active transaction and stop the process immediately. This command applies to Replicat as a whole and cannot be used for a specific Replicat thread.

GETLAG

Shows a true lag time between Replicat and the trail. Lag time is the difference, in seconds, between the time that the last record was processed by Replicat and the timestamp of the record in the trail. The results are the same as LAG REPLICAT.
HANDLECOLLISIONS | NOHANDLECOLLISIONS [table_spec]
Control HANDLECOLLISIONS behavior. Instead of using this option, you can specify the
HANDLECOLLISIONS or NOHANDLECOLLISIONS parameter in the Replicat parameter file.
See "HANDLECOLLISIONS | NOHANDLECOLLISIONS" on page 3-162 for more
information about HANDLECOLLISIONS. This command can be sent directly to an
individual thread by means of SEND REPLICAT group_name[threadID] or you can use
the THREADS option to send the command through the coordinator thread to affect
multiple threads.

HANDLECOLLISIONS
Use HANDLECOLLISIONS to enable automatic error handling when performing
initial data loads while the source database is active. Make certain to disable
HANDLECOLLIONSES, either by issuing SEND REPLICAT with the
NOHANDLECOLLISIONS option or by removing the parameter from the parameter
file, after the initial load is complete and online data changes have been applied to
the target tables.

Note: The message returned by SEND REPLICAT with
HANDLECOLLISIONS, when issued for a specific Replicat thread, shows
that the command set HANDLECOLLISIONS for all MAP statements, not
only the one handled by the specified thread. This is a known issue.
The command actually affects only the MAP statement that includes the
specified thread.

NOHANDLECOLLISIONS
Turns off the HANDLECOLLISIONS parameter but does not remove it from the
parameter file. To avoid enabling HANDLECOLLISIONS the next time Replicat starts,
remove it from the parameter file.

table_spec

table_spec restricts HANDLECOLLISIONS or NOHANDLECOLLISIONS to a specific target
table or a group of target tables specified with a standard wildcard (*).

INTEGRATEDPARAMS(parameter_specification)
(Oracle) Supports an integrated Replicat. Sends a parameter specification to the
database inbound server while Replicat is running in integrated mode. Only one
parameter specification can be send at a time with this command. To send multiple
parameter changes, issue multiple SEND REPLICAT commands as in the following
example.

SEND REPLICAT myrep INTEGRATEDPARAMS ( parallelism 4 )
SEND REPLICAT myrep INTEGRATEDPARAMS ( max_sga_size 250)

To preserve the continuity of processing, the parameter change is made at a transaction
boundary. For a list of supported inbound server parameters, see Installing and
Configuring Oracle GoldenGate for Oracle Database.

REPORT [HANDLECOLLISIONS [table_spec]]
Generates an interim statistical report to the Extract report file. The statistics that are
displayed depend upon the configuration of the STATOPTIONS parameter when used
with the RESETREPORTSTATS | NORESETREPORTSTATS option. See "STATOPTIONS" on
page 3-301.

HANDLECOLLISIONS
Shows tables for which HANDLECOLLISIONS has been enabled.
**table spec**
Restricts the output to a specific target table or a group of target tables specified with a standard wildcard (*).

**RESUME**
Resumes (makes active) a process that was suspended by an `EVENTACTIONS SUSPEND` event. The process resumes normal processing from the point at which it was suspended.

**STATUS**
Returns the current location within the trail and information regarding the current transaction. Fields output are:

- Processing status (per thread, if Replicat is coordinated)
- Position in the trail file (per thread, if Replicat is coordinated)
- Trail sequence number (per thread, if Replicat is coordinated)
- RBA in trail
- Trail name

Possible processing status messages are:

- Delaying – waiting for more data
- Suspended – waiting to be resumed
- Waiting on deferred apply – delaying processing based on the `DEFERAPPLYINTERVAL` parameter.
- Processing data – processing data
- Skipping current transaction – `START REPLICAT with SKIPTRANSACTION` was used.
- Searching for `START ATCSN csn` – `START REPLICAT with ATCSN` was used.
- Searching for `START AFTERCSN csn` – `START REPLICAT with AFTERCSN` was used.
- Performing transaction timeout recovery – Aborting current incomplete transaction and repositioning to start new one (see the `TRANSACTIONTIMEOUT` parameter).
- Waiting for data at logical EOF after transaction timeout recovery – Waiting to receive remainder of incomplete source transaction after a `TRANSACTIONTIMEOUT` termination.
- At EOF (end of file) – no more records to process

Possible thread status messages when `THREADS` is used or the command is issued for a specific thread are:

- Waiting for consensus stop point: This indicates that the threads are attempting to synchronize for a barrier transaction.
- Waiting for Watermark: Indicates that all threads are attempting to stop at the same transaction boundary in the trail, known as the global watermark.
- Waiting on all threads to start up: Indicates that the thread is waiting for all of the threads to start after a successful barrier transaction or a Replicat startup.

Possible coordinator thread status messages are:

- Waiting for all threads to register: Indicates that the `MAP` statements are all being parsed to determine the thread IDs that are specified in them.
- Processing data: Indicates that data is being processed normally.
- Suspended, waiting to be resumed: Indicates that a `SEND REPLICAT` command with a `SUSPEND` request was sent to Replicat.
- At EOF: Indicates that there is no more data in the trail to process.
- Waiting to register MAP statistics: Indicates that Replicat is collecting processing statistics to send to the report file.

**STOP**
Stops Replicat gracefully. This command applies to Replicat as a whole and cannot be used for a specific Replicat thread.

**THREADS (threadID[, threadID][, ...][, thread_range[, thread_range]][, ...])**
Issues the command only for the specified thread or threads of a coordinated Replicat. You can use this option or you can use `groupname` with `threadID`. Without either of those options, the command applies to all active threads.

- `threadID[, threadID][, ...]`
  Specifies a thread ID or a comma-delimited list of threads in the format of `threadID`, `threadID`, `threadID`.

- `thread_range[, thread_range][, ...]`
  Specifies a range of threads in the form of `threadIDlow-threadIDhigh` or a comma-delimited list of ranges in the format of `threadIDlow-threadIDhigh`, `threadIDlow-threadIDhigh`.

A combination of these formats is permitted, such as `threadID`, `threadID`, `threadIDlow-threadIDhigh`.

**TRACE[2] [DDLINCLUDE | DDL[ONLY]] file_name**
Turns tracing on and off. Tracing captures information to the specified file to reveal processing bottlenecks. Tracing also can be enabled by means of the Replicat parameters `TRACE` and `TRACE2`.

If the Replicat is in coordinated mode and `TRACE` is used with a `THREADS` list or range, a trace file is created for each currently active thread. Each file name is appended with its associated thread ID. This method of identifying trace files by thread ID does not apply when `SEND REPLICAT` is issued by `groupname` with `threadID` (as in `SEND REPLICAT fin003 TRACE...`) or when only one thread is specified with `THREADS`.

Contact Oracle Support for assistance if the trace reveals significant processing bottlenecks.

- **TRACE**
  Captures step-by-step processing information.

- **TRACE2**
  Identifies code segments rather than specific steps.

**DDLINCLUDE | DDLONLY**
(Replicat only) Enables DDL tracing and specifies how DDL tracing is included in the trace report.

- **DDLINCLUDE** includes DDL tracing in addition to regular tracing of transactional data processing.
- **DDL[ONLY]** excludes the tracing of transactional data processing and only traces DDL. This option can be abbreviated to **DDL**.
**file_name**

`file_name` specifies the relative or fully qualified name of a file to which Oracle GoldenGate logs the trace information. If a trace is already in progress, the existing trace file is closed and the trace resumes to the file specified with `file_name`. For example:

```
SEND REPLICAT group_name TRACE file_name DDLINCLUDE
```

If no other options will follow the file name, the `FILE` keyword can be omitted, for example:

```
SEND REPLICAT group_name TRACE DDLINCLUDE file_name
```

**TRACE[2] OFF**

Turns off tracing.

**TRACE OFF file_name**

Turns tracing off only for the specified trace file. This option supports the `EVENTACTIONS` feature, where there can be multiple trace files due to multiple `EVENTACTIONS` statements.

**TRACEINIT**

Resets tracing statistics back to 0 and then starts accumulating statistics again. Use this option to track the current behavior of processing, as opposed to historical.

### Examples

**Example 1**

```
SEND REPLICAT finance, HANDLECOLLISIONS
```

**Example 2**

```
SEND REPLICAT finance, REPORT HANDLECOLLISIONS fin_`
```

**Example 3**

```
SEND REPLICAT finance, GETLAG
```

**Example 4**

```
SEND REPLICAT finance, INTEGRATEDPARAMS(parallelism 10)
```

**Example 5**

The following gets lag for thread 3 of a coordinated Replicat.

```
SEND REPLICAT fin003, GETLAG
```

**Example 6**

The following enables tracing for only thread 1 of a coordinated Replicat. In this case, because only one thread is being traced, the trace file will not have a `threadID` extension. The file name is `trace.trc`.

```
SEND REPLICAT fin, TRACE THREADS(1) FILE ./dirrpt/trace.trc
```

**Example 7**

The following enables tracing for threads 1, 2, and 3 of a coordinated Replicat. Assuming all threads are active, the tracing produces files `trace001`, `trace002`, and `trace003`. 

```
SEND REPLICAT fin, TRACE THREADS(1,2,3) FILE ./dirrpt/trace.trc
```
SEND REPLICAT fin TRACE THREADS(1-3) FILE ./dirrpt/trace.trc

Example 8
The following enables tracing only for thread 1 of a coordinated Replicat. Because the command was issued directly for thread 1 without the use of a THREAD clause, the trace file is named trace (without a thread ID suffix).

SEND REPLICAT fin001 TRACE FILE ./dirrpt/trace.trc
Use **START REPLI CAT** to start Replicat. To confirm that Replicat has started, use the **INFO REPLI CAT** or **STATU S REPLI CAT** command.

When starting an integrated Replicat group for an Oracle target database, **START REPLI CAT** automatically registers Replicat with the target database. See *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about integrated Replicat.

A coordinated Replicat can only be started as a whole. There is no option to start individual threads. If the prior shutdown of a coordinated Replicat was not clean, the threads may have stopped at different positions in the trail file. If this happens, **START REPLI CAT** writes a warning if the parameter file was changed since the prior run and raises an error if the number of threads was changed. To resolve these problems and start Replicat again, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Normal Start Point**

Replicat can be started at its normal start point (from initial or current checkpoints) or from an alternate, user-specified position in the trail.

**START REPLI CAT**, without any options, causes Replicat to start processing at one of the following points to maintain data integrity:

- After graceful or abnormal termination: At the first unprocessed transaction in the trail from the previous run, as represented by the current read checkpoint.
- First-time startup after the group was created: From the beginning of the active trail file (seqno 0, rba 0).

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about checkpoints.

**Alternate Start Point**

The **SKIP TRANSACTION**, **ATCSN**, and **AFTERCSN** options of **START REPLI CAT** cause Replicat as a whole, or specific threads of a coordinated Replicat, to begin processing at a transaction in the trail other than the normal start point. Use these options to:

- Specify a logical recovery position when an error prevents Replicat from moving forward in the trail. Replicat can be positioned to skip the offending transaction or transactions, with the understanding that the data will not be applied to the target.
- Skip replicated transactions that will cause duplicate-record and missing-record errors after a backup is applied to the target during an initial load. These options cause Replicat to discard transactions that occurred earlier than the most recent set of changes that were captured in the backup. You can map the value of the serial identifier that corresponds to the completion of the backup to a CSN value, and then start Replicat to begin applying transactions from the specified CSN onward.
Note: Skipping a transaction, or starting at or after a CSN, might cause Replicat to start more slowly than normal, depending on how much data in the trail must be read before arriving at the appropriate transaction record. To view the startup progress, use the SEND REPPLICAT command with the STATUS option. To omit the need for Replicat to read through transactions that ultimately will be skipped, you can use the ATCSN or AFTERCSN option when starting Extract and the data pumps, so that those transactions are omitted from the trail. See "START EXTRACT" on page 1-48.

See Administering Oracle GoldenGate for Windows and UNIX for more information about performing an initial load.

Syntax

START_REPLICAT  group_name
[SKIPTRANSACTION | {ATCSN  csn | AFTERCSN  csn}]
[FILTERDUPTRANSACTIONS]
[THREADS (threadID[, threadID][, ...][, thread_range[, thread_range]][, ...])]

group_name
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* starts all Replicat groups whose names begin with T.

SKIPTRANSACTION
Causes Replicat to skip the first transaction after its expected startup position in the trail. All operations from that first transaction are excluded.

If the MAXTRANSOPS parameter is also being used for this Replicat, it is possible that the process will start to read the trail file from somewhere in the middle of a transaction. In that case, the remainder of the partial transaction is skipped, and Replicat resumes normal processing from the next begin-transaction record in the file. The skipped records are written to the discard file if the DISCARDFILE parameter is being used; otherwise, a message is written to the report file that is similar to:

User requested START SKIPTRANSACTION. The current transaction will be skipped. Transaction ID txid, position Seqno seqno, RBA rba

SKIPTRANSACTION is valid only when the trail that Replicat is reading is part of an online change synchronization configuration (with checkpoints). Not valid for task-type initial loads (where SPECIALRUN is used with ADD REPLICAT).

ATCSN  csn | AFTERCSN  csn
Sets a user-defined start point at a specific CSN. When ATCSN or AFTERCSN is used, a message similar to one of the following is written to the report file:

User requested start at commit sequence number (CSN) csn-string
User requested start after commit sequence number (CSN) csn-string

General information about these options:

- Valid only when the trail that Replicat is reading is part of an online change synchronization configuration (with checkpoints). Not valid for task-type initial loads (where SPECIALRUN is used with ADD REPLICAT).

- To support starting at, or after, a CSN, the trail must be of Oracle GoldenGate version 10.0.0 or later, because the CSN is stored in the first trail record of each transaction. If Replicat is started with AFTERCSN against an earlier trail version,
Replicat will abend and write an error to the report stating that the trail format is not supported.

**ATCSN**
Causes Replicat to start processing at the transaction that has the specified CSN. Any transactions in the trail that have CSN values that are less than the specified one are skipped.

**AFTERCSN**
Causes Replicat to start processing at the transaction that occurred after the one with the specified CSN. Any transactions in the trail that have CSN values that are less than, or equal to, the specified one are skipped.

**csn**
Specifies a CSN value. Enter the CSN value in the format that is valid for the database. See *Administering Oracle GoldenGate for Windows and UNIX* for CSN formats and descriptions. Replicat abends if the format is invalid and writes a message to the report file. To determine the CSN to supply after an initial load is complete, use the commit identifier at which the load utility completed the load. Otherwise, follow the instructions in the initial load procedure for determining when to start Replicat.

**FILTERDUPTRANSACTIONS**
Causes Replicat to ignore transactions that it has already processed. Use when Extract was repositioned to a new start point (see the ATCSN or AFTERCSN option of "START EXTRACT" on page 1-48) and you are confident that there are duplicate transactions in the trail that could cause Replicat to abend. This option requires the use of a checkpoint table. If the database is Oracle, this option is valid only for Replicat in nonintegrated mode. Integrated mode handles duplicate transactions transparently.

**THREADS (threadID[, threadID][, ...][, thread_range[, thread_range]][, ...])**
Valid for SKIPTRANSACTION, ATCSN, and AFTERCSN when Replicat is in coordinated mode. Not valid for START REPLICAT without those options. Starts the specified Replicat thread or threads at the specified location.

- **threadID[, threadID][, ...]**
  Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

- **thread_range[, thread_range][, ...]**
  Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

**Examples**

**Example 1**
START REPLICAT finance

**Example 2**
The following starts Replicat at an Oracle-specific CSN.

START REPLICAT finance, ATCSN 6488359
Example 3
The following starts Replicat at a SQL Server-specific CSN after the one with the specified CSN.

START REPLICAT finance, AFTERCSN 0X0000002:000162E:0009

Example 4
The following causes threads 4 and 5 of a coordinated Replicat to skip the first transaction after their last checkpoint when Replicat is started. If this were a 10-thread coordinated Replicat, threads 0-3 and 6-10 would all start at the normal start point, that of their last checkpoint.

START REPLICAT fin SKIPTRANSACTION THREADS(4-5)

Example 5
The following example causes threads 1-3 of a coordinated Replicat to start at CSN 6488359, threads 9-10 to start after CSN 6488360, and threads 7 and 8 to skip the first transaction after its last checkpoint.

START REPLICAT fin ATCSN 6488359 THREADS(1-3), AFTERCSN 6488360 THREADS(9-10), SKIPTRANSACTION THREADS(7,8)
Use `STATS REPLICAT` to display statistics for one or more Replicat groups. Thread statistics for a coordinated Replicat group are provided as follows.

**Thread Lag Gap**
The difference between the maximum lag and the minimum lag among all threads.

**Coordinated Total DDLs**
The total number of coordinated DDL transactions.

**Coordinated Total PK-Update Transactions**
The total number of coordinated transactions that involved an update to a primary key.

**Coordinated Total EMI Transactions**
The total number of coordinated `EVENTACTIONS` events.

**Total Transactions with User-requested Coordination**
The total number of coordinations that were explicitly requested in the configuration by means of the `COORDINATED` option of the `MAP` parameter.

**Average Coordination Time**
The average time (in seconds) spent in coordination among all threads.

### Syntax

```markdown
STATS REPLICAT  group_name
[, statistic]
[, TABLE [container. | catalog.]schema.table]
[, TOTALONLY [container. | catalog.]schema.table]
[, REPORTCDR]
[, REPORTCHARCONV]
[, REPORTDETAIL | NOREPORTDETAIL]
[, REPORTRATE {HR | MIN | SEC}]
[, ... ]
```

**group_name**
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* shows statistics for all Replicat groups whose names begin with T.

**statistic**
The statistic to be displayed. More than one statistic can be specified by separating each with a comma, for example `STATS REPLICAT finance, TOTAL, DAILY`.

Valid values are:

- **TOTAL**
  Displays totals since process startup.

- **DAILY**
  Displays totals since the start of the current day.

- **HOURLY**
  Displays totals since the start of the current hour.
LATEST
Displays totals since the last RESET command.

RESET
Resets the counters in the LATEST statistical field.

TABLE [container. | catalog.]schema.table]
Displays statistics only for the specified table or a group of tables specified with a wildcard (*). The table name or wildcard specification must be fully qualified with the two-part or three-part name, for example hr.emp or *.*.*.

TOTALONLY [container. | catalog.]schema.table]
Summarizes the statistics for the specified table or a group of tables specified with a wildcard (*). The table name or wildcard specification must be fully qualified with the two-part or three-part name, for example hr.emp or *.*.*.

REPORTCDR
Shows statistics for Conflict Detection and Resolution. Statistics include:
- Total CDR conflicts
- CDR resolutions succeeded
- CDR resolutions failed
- CDR INSERTROWEXISTS conflicts
- CDR UPDATEROWEXISTS conflicts
- CDR DELROWEXISTS conflicts
- CDR DELROWMISSING conflicts

REPORTCHARCONV
Reports statistics for character validation when character-set conversion is performed. The following statistics are added to the STATS output:
Total column character set conversion failure: the number of validation or conversion failures in the current Replicat run.
Total column data truncation: the number of times that column data was truncated in the current Replicat run as the result of character set conversion.

REPORTDETAIL | NOREPORTDETAIL
Controls whether or not the output includes operations that were not replicated as the result of collision errors. These operations are reported in the regular statistics (inserts, updates, and deletes performed) plus as statistics in the detail display, if enabled. For example, if 10 records were insert operations and they were all ignored due to duplicate keys, the report would indicate that there were 10 inserts and also 10 discards due to collisions. The default is REPORTDETAIL. See also “STATOPTIONS” on page 3-301.

REPORTRATE (HR | MIN | SEC)
Displays statistics in terms of processing rate rather than absolute values.

HR
Sets the processing rate in terms of hours.

MIN
Sets the processing rate in terms of minutes.
**SEC**
Sets the processing rate in terms of seconds.

**Examples**

**Example 1**
The following example displays total and hourly statistics per minute for a specific table, and it also resets the latest statistics. Statistics for discarded operations are not reported.

```plaintext
STATS REPLICAT finance, TOTAL, HOURLY, TABLE sales.acct,
REPORTRATE MIN, RESET, NOREPORTDETAIL
```

**Example 2**
The following example displays the same statistics as the previous example, but for thread 3 of a coordinated Replicat group.

```plaintext
STATS REPLICAT fin003, TOTAL, HOURLY, TABLE sales.acct,
REPORTRATE MIN, RESET, NOREPORTDETAIL
```
STATUS REPLICAT

Use STATUS REPLICAT to determine whether or not Replicat is running. There are the following four possible statuses:

**Abended**
The process has abnormally ended.

**Running**
Means one of the following:
- **Active**: Running and processing (or able to process) data. This is the normal state of a process after it is started.
- **Suspended**: The process is running, but suspended due to an EVENTACTIONS SUSPEND action. In a suspended state, the process is not active, and no data can be processed, but the state of the current run is preserved and can be continued by issuing the RESUME command in GGSCI. The RBA in the INFO command reflects the last checkpointed position before the suspend action. To determine whether the state is active or suspended, issue a SEND EXTRACT|REPLICAT group_name STATUS command. For more information, see SEND EXTRACT or SEND REPLICAT.

**Starting**
The process is starting.

**Stopped**
The process was stopped.

Syntax

```plaintext
STATUS REPLICAT group_name
[, TASKS]
[, ALLPROCESSES]
```

**group_name**
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* shows status for all Replicat groups whose names begin with T.

**TASKS**
Displays status only for Replicat tasks. By default, tasks are not displayed unless you specify a single Replicat group (without wildcards).

**ALLPROCESSES**
Displays status for all Replicat groups, including tasks.

Examples

**Example 1**
STATUS REPLICAT finance

**Example 2**
STATUS REPLICAT fin*
STOP REPLICAT

Use **STOP REPLICAT** to stop Replicat cleanly. This command preserves the state of synchronization for the next time Replicat starts, and it ensures that Manager does not automatically start Replicat.

In a clean shutdown of a coordinated Replicat, the coordinator thread attempts to stop all of the threads on the same transaction boundary. If the shutdown of a coordinated Replicat is not clean, the threads may stop at different positions in the trail file. If this happens, **START REPLICAT** writes a warning if the parameter file was changed since the prior run and raises an error if the number of threads was changed. To resolve these problems and start Replicat again, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Syntax**

```
STOP REPLICAT  group_name  [!]  
```

*group_name*

The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* stops all Replicat groups whose names begin with T.

! (Exclamation point) Stops Replicat immediately. The transaction is aborted and the process terminates.

**Example**

```
STOP REPLICAT  finance
```
SYNCHRONIZE REPLICAT

Use `SYNCHRONIZE REPLICAT` to return all of the threads of a coordinated Replicat to the same position in the trail file after an unclean shutdown. This position is the maximum checkpoint position of all of the threads, in other words, the most recent trail record processed among all of the threads. When `SYNCHRONIZE REPLICAT` is issued, all threads are started and allowed to process transactions until they reach the maximum checkpoint position, and then Replicat stops.

For more information about how to use `SYNCHRONIZE REPLICAT` to recover a coordinated Replicat after an unclean shutdown, or to enable repartitioning of data among different threads, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Syntax**

```
SYNCHRONIZE REPLICAT group_name
```

*group_name*

The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* synchronizes the threads of all Replicat groups whose names begin with T. The threads synchronize to the same position within their group, not to the same position across all Replicat groups being synchronized with this command.

**Example**

```
SYNCHRONIZE REPLICAT repA
```
UNREGISTER REPLICAT

Use the UNREGISTER REPLICAT command to unregister a Replicat group from a target Oracle database to disable integrated Replicat mode. Use this command only if you forcibly deleted the Replicat group. UNREGISTER REPLICAT should not be used when deleting Replicat in the normal manner, where you first stop Replicat and then issue the DELETE REPLICAT command.

Before issuing this command, issue the DBLOGIN command as the Replicat database user with privileges granted through dbms_goldengate_auth.grant_admin_privilege.

For more information about integrated Replicat, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Syntax

UNREGISTER REPLICAT group_name DATABASE

group_name
The name of a Replicat group or a wildcard (*) to specify multiple groups. For example, T* unregisters all Replicat groups whose names begin with T.

DATABASE
Required keyword to unregister from the target database. Removes the database inbound server that is associated with this Replicat.

Example

UNREGISTER REPLICAT sales DATABASE
ER

Use the ER commands to control multiple Extract and Replicat groups as a unit. Use them with wildcards to affect every Extract and Replicat group that satisfies the wildcard.

Syntax

```
COMMAND ER wildcard_specification
```

**COMMAND**
Can be any of the following:

- INFO
- KILL
- LAG
- SEND
- START
- STATS
- STATUS
- STOP

For descriptions and optional documentation. For a list of command categories, see "Summary of Oracle GoldenGate Commands" on page 1-1.

**ER**
A required keyword indicating that the command affects both Extract (E) and Replicat (R).

**wildcard_specification**
The wildcard specification for the groups that you want to affect with the command. Oracle GoldenGate will automatically increase internal storage to track up to 100,000 wildcard entries.

Example

The following example starts and then stops the Extract and Replicat groups whose names contain the letter X.

```
START ER *X*
STOP ER *X*
```
CREATE WALLET

Use the CREATE WALLET command to create a master-key wallet. This wallet stores the master key that is used by Oracle GoldenGate processes to encrypt the encryption keys that secure data over the network and in trail files and other Oracle GoldenGate files that store sensitive data.

This command creates an empty wallet that remains open for the duration of the GGSCI session. The GGSCI console returns messages similar to the following, indicating that the wallet is present and open.

Created wallet at location './dirwlt'.
Opened wallet at location './dirwlt'.

The wallet is created as an autologin wallet (file extension .sso) to support automated restarts of Oracle GoldenGate processes without requiring human intervention to supply the necessary decryption passwords. The wallet file is created in the directory specified by the GLOBALS parameter WALLETLOCATION, if present, or otherwise in the default location of dirwlt in the Oracle GoldenGate installation directory.

The wallet is in a platform-independent format. It must either be stored on a shared file system that is accessible by all systems in the Oracle GoldenGate environment, or it must be copied to all of those systems initially and every time the master key changes.

The wallet is permanent within Oracle GoldenGate, but can be manually deleted with the appropriate command in the operating system, if that becomes necessary.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

See "ADD MASTERKEY" on page 1-93 to add a master key value to the wallet.

Syntax

CREATE WALLET
OPEN WALLET

Use the OPEN WALLET command to open a master-key wallet. Opening a wallet decrypts the contents and loads them into the GGSCI memory. This command must be used before using any of the commands that add, renew, or delete the master keys in the wallet.

The wallet remains open for the rest of the GGSCI session. The name of the wallet to be opened is taken from the GLOBALS parameter WALLETLOCATION, if present, or otherwise it is opened from the default location in the Oracle GoldenGate installation directory.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

Syntax

OPEN WALLET
PURGE WALLET

Use the PURGE WALLET command to permanently remove master key versions from the master-key wallet. Only the versions that are marked for deletion by the DELETE MASTERKEY command are removed. The purge is not reversible.

Note: For Oracle GoldenGate deployments using a shared wallet, the older versions of the master key should be retained after the master key is renewed until all processes are using the newest version. The time to wait depends on the topology, latency, and data load of the deployment. A minimum wait of 24 hours is a conservative estimate, but you may need to perform testing to determine how long it takes for all processes to start using a new key. To determine whether all of the processes are using the newest version, view the report file of each Extract immediately after renewing the master key to confirm the last SCN that was mined with the old key. Then, monitor the Replicat report files to verify that this SCN was applied by all Replicat groups. At this point, you can delete the older versions of the master key.

The OPEN WALLET command must be used before using this command or any of the commands that add, renew, or delete the master keys in the wallet.

After purging a wallet that is not maintained centrally on shared storage, the updated wallet can be copied to all of the other systems in the Oracle GoldenGate configuration that use this wallet, so that no purged keys remain in the configuration. Before doing so, Extract must be stopped and then all of the downstream Oracle GoldenGate processes must be allowed to finish processing their trails and then be stopped. After the wallet is copied into place, the processes can be started again. For detailed instructions, see Administering Oracle GoldenGate for Windows and UNIX.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

Syntax

PURGE WALLET
Use the ADD MASTERKEY command to add a master key to a master-key wallet. The master key is used by Extract and Replicat to encrypt the encryption keys that secure data being sent across the network and in the trail files, so that those keys can be sent to, and used, by downstream processes. The master key omits the need to use wallet storage for the keys that actually encrypt the data.

The master-key wallet must be open to add a key. Use the CREATE WALLET or OPEN WALLET command to open a wallet. The wallet remains open throughout the same GGSCI session in which the command was issued.

The master key is generated as a random sequence of bits. The length is 256 bits by default. The key name is OGG_DEFAULT_MASTERKEY.

The successful completion of this command returns a message similar to the following:

```
Masterkey 'OGG_DEFAULT_MASTERKEY' added to wallet at location './dirwlt'.
```

After adding a master key to a wallet that is not maintained centrally on shared storage, the updated wallet must be copied to all of the other systems in the Oracle GoldenGate configuration that use this wallet. Before doing so, Extract must be stopped and then all of the downstream Oracle GoldenGate processes must be allowed to finish processing their trails and then be stopped. After the wallet is copied into place, the processes can be started again. For detailed instructions, see Administering Oracle GoldenGate for Windows and UNIX.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

**Syntax**

```
ADD MASTERKEY
```

**Example**

This example creates a new master key.

```
ADD MASTERKEY
```
INFO MASTERKEY

Use the INFO MASTERKEY command to view the contents of a currently open master-key wallet. The default output shows the version history of the master key, with the creation date of a version and the status of the version. The status can be one of the following:

- **Current**: Indicates this is the active version of the master key.
- **Available**: Indicates this version is not the current one but can be made active, if needed.
- **Deleted**: Indicates that this version is marked to be deleted when the PURGE WALLET command is issued.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

**Syntax**

INFO MASTERKEY [VERSION version]

**VERSION version**
Shows detailed information about a specific version of the master key. The output includes the original creation date, the latest renewal date, the status, and the hash of AES (Advanced Encryption Standard) Key).

**Examples**

**Example 1**
The following example shows the default input without any options.

INFO MASTERKEY

<table>
<thead>
<tr>
<th>Masterkey Name:</th>
<th>OGG_DEFAULT_MASTERKEY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation Date:</td>
<td>Mon Aug 27 10:00:40 2012</td>
</tr>
<tr>
<td>Version:</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>Mon Aug 27 10:00:40 2012</td>
</tr>
<tr>
<td>2</td>
<td>Mon Aug 27 10:00:46 2012</td>
</tr>
<tr>
<td>3</td>
<td>Mon Aug 27 10:02:58 2012</td>
</tr>
<tr>
<td>4</td>
<td>Mon Aug 27 10:03:02 2012</td>
</tr>
<tr>
<td>5</td>
<td>Mon Aug 27 10:03:05 2012</td>
</tr>
<tr>
<td>6</td>
<td>Mon Aug 27 10:03:09 2012</td>
</tr>
<tr>
<td>7</td>
<td>Mon Aug 27 10:03:16 2012</td>
</tr>
</tbody>
</table>

**Example 2**
The following example shows the results of INFO MASTERKEY with VERSION. The status of Current in the output shows that version 7 is the active version.

INFO MASTERKEY VERSION 7

<table>
<thead>
<tr>
<th>Masterkey Name:</th>
<th>OGG_DEFAULT_MASTERKEY</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creation Date:</td>
<td>Mon Aug 27 10:00:40 2012</td>
</tr>
<tr>
<td>Version:</td>
<td>7</td>
</tr>
<tr>
<td>Renew Date:</td>
<td>Mon Aug 27 10:03:16 2012</td>
</tr>
<tr>
<td>Status:</td>
<td>Current</td>
</tr>
<tr>
<td>Key Hash (SHA1):</td>
<td>0xC65ADFA1CF42F9DB2CED3BC39A53F661CDED3304</td>
</tr>
</tbody>
</table>
RENEW MASTERKEY

Use the RENEW MASTERKEY command to create a new version of the master encryption key in the master-key wallet. The key name remains the same, but the bit ordering is different. All versions of a master key remain in the wallet until they are marked for deletion with the DELETE MASTERKEY command and then the wallet is purged with the PURGE WALLET command.

The OPEN WALLET command must be used before using this command or any of the commands that add or delete the master keys or purge the wallet.

A message similar to the following indicates that the command succeeded.

Masterkey 'OGG_DEFAULT_MASTERKEY' renewed to version 2 in wallet at location './dirwlt'.

After renewing a master key in a wallet that is not maintained centrally on shared storage, the updated wallet must be copied to all of the other systems in the Oracle GoldenGate configuration that use this wallet. Before doing so, Extract must be stopped and then all of the downstream Oracle GoldenGate processes must be allowed to finish processing their trails and then be stopped. After the wallet is copied into place, the processes can be started again. For detailed instructions, see Administering Oracle GoldenGate for Windows and UNIX.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

Syntax

RENEW MASTERKEY

Example

This example creates a new version of the master key.

RENEW MASTERKEY
DELETE MASTERKEY

Use the DELETE MASTERKEY command to mark a version of a master key for deletion. Routinely deleting older versions of a master key ensures that they cannot be used maliciously.

The OPEN WALLET command must be used before using this command or any of the commands that add or renew the master keys or purge the wallet.

To view the version of a master key, use the INFO MASTERKEY command.

This command marks a version for deletion but does not physically remove it from the wallet. See "PURGE WALLET" on page 1-92 to remove the master key version permanently.

**Note:** For Oracle GoldenGate deployments using a shared wallet, the older versions of the master key should be retained after the master key is renewed until all processes are using the newest version. The time to wait depends on the topology, latency, and data load of the deployment. A minimum wait of 24 hours is a conservative estimate, but you may need to perform testing to determine how long it takes for all processes to start using a new key. To determine whether all of the processes are using the newest version, view the report file of each Extract immediately after renewing the master key to confirm the last SCN that was mined with the old key. Then, monitor the Replicat report files to verify that this SCN was applied by all Replicat groups. At this point, you can delete the older versions of the master key.

See "UNDELETE MASTERKEY" on page 1-98 to reverse a deletion made by DELETE MASTERKEY.

Once a version number is used, the wallet reserves it forever, and no other key of the same version can be generated. For example, you cannot mark version 2 of a key for deletion, then purge the wallet to remove it, and then issue RENEW MASTERKEY to add a version 2 again. Even though only version 1 of the key remains in the wallet after the purge, the renewal generates version 3, not version 2.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

**Syntax**

```
DELETE MASTERKEY
{VERSION version | RANGE FROM begin_value TO end_value | ALL}

VERSION version
Specifies a single version to be marked for deletion.

RANGE FROM begin_value TO end_value
Specifies a range of versions to be marked for deletion. The versions must be contiguous. For example, specifying RANGE FROM 3 TO 6 marks versions 3, 4, 5, and 6.

ALL
Marks all versions of the master key for deletion, including the currently active one. When this option is used, it should always be followed by a RENEW MASTERKEY command to create a new, current version of the master key.
```
Examples

Example 1
This command marks one version of the master key for deletion and returns a message similar to the one shown.

DELETE MASTERKEY VERSION 10
Version 10 of Masterkey 'OGG_DEFAULT_MASTERKEY' deleted from wallet at location './dirwlt'.

Example 2
This command marks versions 3, 4, 5, and 6 for deletion and returns a message similar to the one shown.

DELETE MASTERKEY RANGE FROM 3 TO 6

Version 3 of Masterkey 'OGG_DEFAULT_MASTERKEY' deleted from wallet at location './dirwlt'.
Version 4 of Masterkey 'OGG_DEFAULT_MASTERKEY' deleted from wallet at location './dirwlt'.
Version 5 of Masterkey 'OGG_DEFAULT_MASTERKEY' deleted from wallet at location './dirwlt'.
Version 6 of Masterkey 'OGG_DEFAULT_MASTERKEY' deleted from wallet at location './dirwlt'.

UNDELETE MASTERKEY

Use the UNDELETE MASTERKEY command to remove the deletion mark from a master key version, thus retaining that version if the PURGE WALLET command is used. Only one version can be unmarked per UNDELETE MASTERKEY command. See "DELETE MASTERKEY" on page 1-96 to mark a version of a master key for deletion.

The OPEN WALLET command must be used before using this command or any of the commands that add, renew, or delete the master keys in the wallet.

The use of a wallet and master key is not supported for the iSeries, z/OS, and NonStop platforms.

Syntax

UNDELETE MASTERKEY VERSION version

VERSION version
The version that is to be unmarked for deletion.

Example

This command unmarks version 3 of the master key and returns a message similar to the one shown.

UNDELETE MASTERKEY VERSION 3
Version 3 of Masterkey 'OGG_DEFAULT_MASTERKEY' undeleted from wallet at location './dirwlt'.
ADD CREDENTIALSTORE

Use the ADD CREDENTIALSTORE command to create a credential store. The credential store manages user IDs and their encrypted passwords (together known as credentials) that are used by Oracle GoldenGate processes to interact with the local database. The credential store eliminates the need to specify user names and clear-text passwords in the Oracle GoldenGate parameter files. An optional alias can be used in the parameter file instead of the user ID to map to a userid-password pair in the credential store.

The credential store is implemented as an autologin wallet within the Oracle Credential Store Framework (CSF). The use of an LDAP directory is not supported for the Oracle GoldenGate credential store. The autologin wallet supports automated restarts of Oracle GoldenGate processes without requiring human intervention to supply the necessary passwords.

ADD CREDENTIALSTORE creates an empty credentials store in the location that is specified with the CREDENTIALSTORELOCATION parameter in the GLOBALS file, if used, or otherwise in the default location of dircrd in the Oracle GoldenGate installation directory. A credential store can be shared by multiple instances (installations) of Oracle GoldenGate on the same or different systems. Store a shared credential store in a shared file system, and specify this location in each Oracle GoldenGate instance by using the CREDENTIALSTORELOCATION parameter in each GLOBALS parameter file.

Only one credential store can be used at a time by any given instance of Oracle GoldenGate. For example, you can have a credential store named /home/ogg/credentials and a credential store named /test/ogg/credentials, but only one can be used at runtime by a given instance of Oracle GoldenGate. You can stop the processes to switch to a different credential store, but make certain to update the CREDENTIALSTORELOCATION parameter in each GLOBALS parameter file, and change the USERIDALIAS parameters to specify different aliases if needed.

See "ALTER CREDENTIALSTORE" on page 1-100 to add credentials to the credentials store.

The use of a credential store is not supported for the iSeries, z/OS, and NonStop platforms.

For more information about Oracle GoldenGate security options, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

ADD CREDENTIALSTORE
Use the `ALTER CREDENTIALSTORE` command to manage user ID and password pairs in the credential store. This command enables you to add credentials to the credential store and to specify different aliases for a user. Upon successful completion, the command returns a message similar to the following:

Credential store altered.

The use of a credential store is not supported for the iSeries, z/OS, and NonStop platforms.

For more information about Oracle GoldenGate security options, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Syntax**

```
ALTER CREDENTIALSTORE { 
  ADD USER userid | 
  REPLACE USER userid | 
  DELETE USER userid 
} 
[PASSWORD password] 
[ALIAS alias] 
[DOMAIN domain]
```

**ADD USER userid**

Adds the specified user and its alias to the credential store. If the `ALIAS` option is not used, the alias defaults to the user name. A credential can only be entered once unless the `ALIAS` option is used to specify a different alias for each one. Unless the `PASSWORD` option is used, the command prompts for the password of the specified user. The user can be an actual user name or a SQL*Net connect string.

**REPLACE USER userid**

Changes the password of the specified user. If the `ALIAS` option is not used, the alias defaults to the user name. You cannot change the alias or domain of a user with this option, but you can use the `ADD USER` option to add a new entry for the user under the desired `ALIAS` or `DOMAIN`. Unless the `PASSWORD` option is used, the command prompts for the new password for the specified user.

**DELETE USER userid**

Removes the credential for the specified user from the credential store. If the `ALIAS` option is not used, the alias defaults to the user name.

**PASSWORD password**

The user’s password. The password is echoed (not obfuscated) when this option is used. If this option is omitted, the command prompts for the password, which is obfuscated as it is typed (recommended as more secure).

```
ALTER CREDENTIALSTORE ADD USER scott 
Password: ********
```

**ALIAS alias**

Specifies an alias for the user name. Use this option if you do not want the user name to be in a parameter file or command. If `ALIAS` is not used, the alias defaults to the `USER` name, which then must be used in parameter files and commands where a login is required. You can create multiple entries for a user, each with a different alias, by using the `ADD USER` option with `ALIAS`.

---

1-100  Reference for Oracle GoldenGate for Windows and UNIX
DOMAIN domain
Saves the credential user under the specified domain name. Enables the same alias to
be used by multiple Oracle GoldenGate installations that use the same credential store.
The default domain is Oracle GoldenGate. For example, the administrators of system
1 might not want system 2 to have access to the same credentials that are used on
system 1. Those credentials can be stored as ALIAS extract, for example, under
DOMAIN system1, while a different set of credentials can be stored for ALIAS extract
under DOMAIN system2. See “ADD CREDENTIALSTORE” on page 1-99 for information
about how to use a shared credential store.

Examples

Example 1
This example adds a user named scott but omits the PASSWORD specification, so the
command prompts for Scott’s password.

ALTER CREDENTIALSTORE ADD USER scott
Password: ********

Example 2
This example adds the user scott with his password tiger and specifies an alias for
scott that is named scsm2.

ALTER CREDENTIALSTORE ADD USER scott PASSWORD tiger ALIAS scsm2

Example 3
This example adds the user scott under the domain of support.

ALTER CREDENTIALSTORE ADD USER scott ALIAS scsm3 DOMAIN support
Password: ********

Example 4
This example issues two ALTER CREDENTIALSTORE commands, each of which adds a
scott entry, but with a different alias.

ALTER CREDENTIALSTORE ADD USER scott ALIAS scsm2
Password: ********
ALTER CREDENTIALSTORE ADD USER scott ALIAS scsm3
Password: ********

Example 5
The following shows how the DELETE USER option works with and without the ALIAS
option.
The following command deletes the user1 entry for which the ALIAS is the same as the
user name.

ALTER CREDENTIALSTORE DELETE USER user1
Alias: user1
Userid: user1

The following command deletes the entry for user user1 that is associated with the
alias alias1.

ALTER CREDENTIALSTORE DELETE USER user1 ALIAS alias1
Alias: alias1
Userid: user1
Example 6

This example uses a SQL*Net connect string as the user value. In this case, the PASSWORD option is omitted. The person issuing the command will be prompted for the password, which is obfuscated.

```
ALTER CREDENTIALSTORE ADD USER oggext1@oral ALIAS oral
```
INFO CREDENTIALSTORE

Use the INFO CREDENTIALSTORE command to get information about an Oracle GoldenGate credential store. This information includes the aliases that a credential store contains and the user IDs that correspond to them. The encrypted passwords in the credential store are not returned.

The credential store location is identified by the CREDENTIALSTORELOCATION parameter in the GLOBALS file, if one exists, or otherwise by the default location of dircrd in the Oracle GoldenGate installation directory.

The use of a credential store is not supported for the iSeries, z/OS, and NonStop platforms.

For more information about Oracle GoldenGate security options, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

INFO CREDENTIALSTORE [DOMAIN domain]

DOMAIN domain
Returns the aliases and user IDs for a specific domain. For security purposes, if the DOMAIN option is omitted, only the aliases and user IDs under the default domain of OracleGoldenGate are shown. It is not possible to see DOMAIN credentials unless the person issuing the INFO CREDENTIALSTORE command knows the name of the domain. See "ALTER CREDENTIALSTORE" on page 1-100 for more information about domains.

Examples

Example 1
The following example shows the default output of INFO CREDENTIALSTORE.

INFO CREDENTIALSTORE
Domain: OracleGoldenGate
  Alias: support1
  Userid: scott
  Alias: sales1
  Userid: scott

Example 2
The following example shows the output when DOMAIN is used.

INFO CREDENTIALSTORE DOMAIN support
Domain: Support
  Alias: support1
  Userid: scott
DELETE CREDENTIALSTORE

Use the `DELETE CREDENTIALSTORE` command to remove a credential store from the system. The credential store wallet and its contents are permanently deleted.

The use of a credential store is not supported for the iSeries, z/OS, and NonStop platforms.

For more information about Oracle GoldenGate security options, see *Administering Oracle GoldenGate for Windows and UNIX*.

Syntax

```
DELETE CREDENTIALSTORE
```
ADD EXTTRAIL

Use ADD EXTTRAIL to create a trail for online processing on the local system and:

- Associate it with an Extract group.
- Assign a maximum file size.

Syntax

ADD EXTTRAIL trail_name, EXTRACT group_name
[, MEGABYTES n]
[SEQNO n]

trail_name
The relative or fully qualified path name of the trail. The trail name can contain only two characters. Oracle GoldenGate appends this name with a six-digit sequence number whenever a new file is created. For example, a trail named dirdat/tr would have files named dirdat/tr000001, dirdat/tr000002, and so forth.

group_name
The name of the Extract group to which the trail is bound. Only one Extract process can write data to a trail.

MEGABYTES n
The maximum size, in megabytes, of a file in the trail. The default is 100.

SEQNO n
Specifies that the first file in the trail will start with the specified trail sequence number. Do not include any zero padding. For example, to start at sequence 3 of a trail named tr, specify SEQNO 3. The actual file would be named /ggs/dirdat/tr000003. This option can be used during troubleshooting when Replicat needs to be repositioned to a certain trail sequence number. It eliminates the need to alter Replicat to read the required sequence number.

Examples

Example 1
ADD EXTTRAIL dirdat\aa, EXTRACT finance, MEGABYTES 200

Example 2
ADD EXTTRAIL /ggs/dirdat/tr000003
ADD RMTTRAIL

Use `ADD RMTTRAIL` to create a trail for online processing on a remote system and:

- Assign a maximum file size.
- Associate the trail with an Extract group.

In the parameter file, specify a `RMTHOST` entry before any `RMTTRAIL` entries to identify the remote system and TCP/IP port for the Manager process.

**Syntax**

```
ADD RMTTRAIL trail_name, EXTRACT group_name
[, MEGABYTES n]
[, SEQNO n]
```

**trail_name**
The relative or fully qualified path name of the trail. The actual trail name can contain only two characters. Oracle GoldenGate appends this name with a six-digit sequence number whenever a new file is created. For example, a trail named `./dirdat/tr` would have files named `./dirdat/tr000001`, `./dirdat/tr000002`, and so forth.

**group_name**
The name of the Extract group to which the trail is bound. Only one primary Extract process can write data to a remote trail.

**MEGABYTES n**
The maximum size, in megabytes, of a file in the trail. The default is 100.

**SEQNO n**
Specifies that the first file in the trail will start with the specified trail sequence number. Do not include any zero padding. For example, to start at sequence 3 of a trail named `tr`, specify `SEQNO 3`. The actual file would be named `/ggs/dirdat/tr000003`. This option can be used during troubleshooting when Replicat needs to be repositioned to a certain trail sequence number. It eliminates the need to alter Replicat to read the required sequence number.

**Example**

**Example 1**

```
ADD RMTTRAIL dirdat\aa, EXTRACT finance, MEGABYTES 200
```

**Example 2**

```
ADD RMTTRAIL /ggs/dirdat/tr000003
```
ALTER EXTTRAIL

Use ALTER EXTTRAIL to change the attributes of a trail that was created with the ADD EXTTRAIL command (a trail on the local system). The change takes effect the next time that Extract starts.

Syntax

```
ALTER EXTTRAIL trail_name, EXTRACT group_name
[, MEGABYTES n]
```

`trail_name`
The relative or fully qualified path name of the trail. For example, `dirdat\aa`.

`group_name`
The name of the Extract group to which the trail is bound.

`MEGABYTES n`
The maximum size of a file, in megabytes. The default is 100. After using this option, issue the `SEND EXTRACT` command with the ROLLOVER option to close the current trail file and open a new one.

Example

```
ALTER EXTTRAIL dirdat\aa, EXTRACT finance, MEGABYTES 200
```
ALTER RMTTRAIL

Use ALTER RMTTRAIL to change the attributes of a trail that was created with the ADD RMTTRAIL command (a trail on a remote system). The change takes effect the next time that Extract starts.

Syntax

ALTER RMTTRAIL trail_name, EXTRACT group_name
[ , MEGABYTES n ]

trail_name
The relative or fully qualified path name of the trail. For example, dirdat\aa.

group_name
The name of the Extract group to which the trail is bound.

MEGABYTES n
The maximum size of a file, in megabytes. The default is 100. The default is 100. After using this option, issue the SEND EXTRACT command with the ROLLOVER option to close the current trail file and open a new one.

Example

ALTER RMTTRAIL dirdat\aa, EXTRACT finance, MEGABYTES 200
DELETE EXTTRAIL

Use DELETE EXTTRAIL to delete the record of checkpoints associated with a trail on a local system. Checkpoints are maintained in a file bearing the same name as the group in the dirchk sub-directory of the Oracle GoldenGate directory.

This command only deletes references to the specified trail from the checkpoint file. It does not delete the trail files themselves. To delete the trail files, use standard operating system commands for removing files.

See Administering Oracle GoldenGate for Windows and UNIX for more information about checkpoints.

**Syntax**

```
DELETE EXTTRAIL trail_name
```

`trail_name`

The relative or fully qualified path name of the trail, including the two-character trail prefix.

**Example**

```
DELETE EXTTRAIL dirdat/et
```
DELETE RMTTRAIL

Use DELETE RMTTRAIL to delete the record of checkpoints associated with a trail on a remote system. Checkpoints are maintained in a file bearing the same name as the group in the dirchk sub-directory of the Oracle GoldenGate directory.

This command only deletes references to the specified trail from the checkpoint file. It does not delete the trail files themselves. To delete the trail files, use standard operating system commands for removing files.

See Administering Oracle GoldenGate for Windows and UNIX for more information about checkpoints.

Syntax

DELETE RMTTRAIL trail_name[,EXTRACT group_name]

**trail_name**
The relative or fully qualified path name of the trail, including the two-character trail prefix.

**group_name**
The name of the Extract group to which the trail is bound. If not specified, DELETE RMTTRAIL deletes the trail reference from all Extract groups that write to the specified trail.

Example

DELETE RMTTRAIL dirdat/et
INFO EXTTRAIL

Use `INFO EXTTRAIL` to retrieve configuration information for a local trail. It shows the name of the trail, the Extract that writes to it, the position of the last data processed, and the assigned maximum file size.

**Syntax**

`INFO EXTTRAIL trail_name`

*trail_name*

The relative or fully qualified path name of the trail or a wildcard designating multiple trails.

**Examples**

**Example 1**

`INFO EXTTRAIL dirdat\aa`

**Example 2**

`INFO EXTTRAIL *`

**Example 3**

The following is sample output of `INFO EXTTRAIL`.

Extract Trail: c:\gg_81\dirdat\md
  Extract: GGSEXT8
    Seqno: 2
    RBA: 51080
    File Size: 100M
INFO RMTTRAIL

Use INFO RMTTRAIL to retrieve configuration information for a remote trail. It shows the name of the trail, the Extract that writes to it, the position of the last data processed, and the assigned maximum file size.

Syntax

INFO RMTTRAIL trail_name

trail_name
The relative or fully qualified path name of the trail or a wildcard designating multiple trails.

Examples

Example 1
INFO RMTTRAIL dirdat\aa

Example 2
INFO RMTTRAIL *

Example 3
The following is a sample of INFO RMTTRAIL output.

Extract Trail: /gg_81/dirdat/rt
Extract: GGEEXT
Seqno: 4
RBA: 78066
File Size: 100M
EDIT PARAMS

Use EDIT PARAMS to create or change a parameter file. By default, this command launches Notepad on Windows systems or the vi editor on UNIX systems. You can change the editor with the SET EDITOR command.

---

**Caution:** Do not use this command to view or edit an existing parameter file that is in a character set other than that of the local operating system (such as one where the CHARSET option was used to specify a different character set). The contents may become corrupted. View the parameter file from outside GGSCI.

---

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about how to work with parameter files.

**Syntax**

```
EDIT PARAMS (MGR | group_name | file_name)
```

**MGR**

Opens a parameter file for the Manager process.

**group_name**

Opens a parameter file for the specified Extract or Replicat group.

**file_name**

Opens the specified file. When you create a parameter file with EDIT PARAMS in GGSCI, it is saved to the dirprm sub-directory of the Oracle GoldenGate directory. You can create a parameter file in a directory other than dirprm by specifying the full path name, but you must also specify the full path name with the PARAMS option of the ADD EXTRACT or ADD REPPLICAT command when you create the process group.

**Examples**

**Example 1**

```
EDIT PARAMS finance
```

**Example 2**

```
EDIT PARAMS c:\lpparms\replp.prm
```
Use `SET EDITOR` to change the default text editor for the current session of GGSCI. The default editors are Notepad for Windows and vi for UNIX. GGSCI input, including to create parameter files, takes the character set of the local operating system.

**Syntax**

```
SET EDITOR program_name
```

* `program_name`  
Any text editor.

**Example**

The following example changes the default editor to Wordpad.

```
SET EDITOR wordpad
```
VIEW PARAMS

Use `VIEW PARAMS` to view the contents of a parameter file.

---

**Caution:** Do not use this command to view a parameter file that is in a character set other than that of the local operating system (such as one where the `CHARSET` option was used to specify a different character set). The contents may become corrupted. View the parameter file from outside GGSCI.

---

**Syntax**

```
VIEW PARAMS {MGR | group_name | file_name}
```

*MGR*

Shows the Manager parameter file.

*group_name*

Shows the parameter file for the specified Extract or Replicat group.

*file_name*

Shows the specified file. By default, the subdirectory `dirprm` is used if no path is specified. If the parameter file resides in a directory other than `dirprm`, specify the full path name.

**Examples**

**Example 1**

```
VIEW PARAMS finance
```

**Example 2**

```
VIEW PARAMS c:\lpparms\replp.prm
```
DBLOGIN

Use DBLOGIN to establish a database connection through GGSCI in preparation to issue other Oracle GoldenGate commands that affect the database. The user who issues DBLOGIN should have the appropriate database privileges to perform the functions that are enacted by those commands. Any other special privileges that are required for a GGSCI command are listed with the reference documentation for that command.

Requirements When Configuring Extract or Replicat in Integrated Mode (Oracle)
If using DBLOGIN to issue ADD EXTRACT, ALTER EXTRACT, or REGISTER EXTRACT to initiate integrated capture or ADD REPLICAT, ALTER REPLICAT, or REGISTER REPLICAT to initiate integrated Replicat against an Oracle database, the user who issues DBLOGIN must:

- Have privileges granted through the Oracle dbms_goldengate_auth.grant_admin_privilege procedure.
- Not be changed while Extract or Replicat is in integrated mode.

Special Database Privileges to Use Log Retention in Classic Capture Mode
When in classic capture mode for an Oracle database, Extract supports the log-retention feature, whereby the database retains the logs that Extract needs. (See Installing and Configuring Oracle GoldenGate for Oracle Database for more information about classic capture.) To enable the log-retention feature, DBLOGIN must be issued with special privileges before using REGISTER EXTRACT with the LOGRETENTION option. For simplicity, you can log in as the Extract database user if the correct privileges were granted to that user when Oracle GoldenGate was installed. Otherwise, log in as a user with the privileges shown in Table 1–16.

Table 1–16  Oracle Privileges for Log Retention

<table>
<thead>
<tr>
<th>Oracle EE version</th>
<th>How to Grant Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.1 and 11.2.0.1</td>
<td>1. Run package to grant Oracle GoldenGate admin privilege.</td>
</tr>
<tr>
<td></td>
<td>exec dbms_streams_auth.grant_admin_privilege('user')</td>
</tr>
<tr>
<td></td>
<td>2. Grant the 'become user' privilege.</td>
</tr>
<tr>
<td></td>
<td>grant become user to user;</td>
</tr>
<tr>
<td>11.2.0.2 and later</td>
<td>Run package to grant Oracle GoldenGate admin privilege.</td>
</tr>
<tr>
<td></td>
<td>exec dbms_goldengate_auth.grant_admin_privilege('user')</td>
</tr>
</tbody>
</table>

Syntax

DBLOGIN {
[SOURCEDB data_source] |
[], database@host:port] |
USERID {/ | userid}[, PASSWORD password]
   [algorithm ENCRYPTKEY {keyname | DEFAULT}] |
USERIDALIAS alias [DOMAIN domain] |
[SYSDBA | SQLID sqlid]
[SESSIONCHARSET character_set] }

SOURCEDB data_source

SOURCEDB specifies a data source name. This option is required to identify one of the following:
- The source or target login database for Sybase, MySQL, and databases that use ODBC
- The source or target SQL/MX catalog

database@host:port
(MYSQL) Specifies a connection string that contains the database name, host name, and database port number. Can be used to specify a port other than the default that is specified in the database configuration.

USERID
Supplies a database login credential, if required. Can be used if an Oracle GoldenGate credential store is not in use. (See the USERIDALIAS option.) Input varies, depending on the database, as follows:

userid
Specifies the name of a database user or a schema, depending on the database configuration. For Oracle, a SQL*Net connect string can be used. To log into a pluggable database in an Oracle multitenant container database, specify userid as a connect string, such as OGGUSER@FINANCE. To log into the root container, specify userid as a common user, including the C++ prefix, such as C##GGADMIN@FINANCE.

/ (Oracle) Directs Oracle GoldenGate to use an operating-system login for Oracle, not a database user login. Use this argument only if the database allows authentication at the operating-system level. To use this option, the correct user name must exist in the database, in relation to the value of the Oracle OS_AUTHENT_ PREFIX initialization parameter. For more information, see the USERID parameter.

PASSWORD password
Use when authentication is required to specify the password for the database user. If the password was encrypted by means of the ENCRYPT PASSWORD command, supply the encrypted password; otherwise, supply the clear-text password. If the password is case-sensitive, type it that way.

algorithm
If the password was encrypted with the ENCRYPT PASSWORD command, specify the encryption algorithm that was used:

AES128
AES192
AES256
BLOWFISH

ENCRYPTKEY (keyname | DEFAULT)
Specifies the encryption key that was specified with the ENCRYPT PASSWORD command. Use one of the following:

ENCRYPTKEY keyname
Specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if ENCRYPT PASSWORD was used with the KEYNAME keyname option.
ENCRYPTKEY DEFAULT
Directs Oracle GoldenGate to generate a Blowfish key. Use if the ENCRYPT PASSWORD command was used with the KEYNAME DEFAULT option.

USERIDALIAS alias [DOMAIN domain]
Supplies a database login credential, if required. Can be used instead of the USERID option if there is a local Oracle GoldenGate credential store that contains a credential with the required privileges for this DBLOGIN command. For more information about using a credential store, see Administering Oracle GoldenGate for Windows and UNIX.

alias
Specifies the alias of a database user credential that is stored in the Oracle GoldenGate credential store. To log into a pluggable database in an Oracle multitentant container database, the user must be stored as a connect string, such as OGGUSER@FINANCE. To log into the root container, the user must be stored as a common user, including the C++ prefix, such as C##GGADMIN@FINANCE. For more information about configuring Oracle GoldenGate for a CDB, see Installing and Configuring Oracle GoldenGate for Oracle Database.

DOMAIN domain
Specifies the credential store domain for the specified alias. A valid domain entry must exist in the credential store for the specified alias.

SYSDBA
(Oracle) Specifies that the user logs in as sysdba. This option can be used for USERID and USERIDALIAS.

SQLID sqlid
(DB2 on z/OS) Issues the SQL command SET CURRENT SQLID = 'sqlid' after the USERID login (with PASSWORD, if applicable) is completed. If the SET command fails, the entire DBLOGIN command fails as a unit.

SESSIONCHARSET character_set
(Sybase, Teradata and MySQL) Sets a database session character set for the GGSCI connection to the database. All subsequent commands will use the specified session character set. This command option overrides any SESSIONCHARSET that is specified in theGLOBALS file.

(Sybase) To display the language information in the process report file when using this option for a Sybase database, make certain that locale.dat is set properly in the Sybase installation directory. If the character set is not found in the supported Sybase database character set, then it is validated against the Oracle GoldenGate supported character set list. The character-set information is displayed with the LOCALE INFORMATION entry in the report output. When issuing the DBLOGIN command, the Sybase environment variable is examined to see if the language (LANG) is set. If the language is not set, Oracle GoldenGate automatically sets it to US English.

Examples

Example 1
DBLOGIN USERID ogg@ora1.ora, PASSWORD AACAAAAAAAAAAAJAUEUGODSCVGJEEIUGKJDJTFNDKEJFFFTC AES128, ENCRYPTKEY securekey1

Example 2
DBLOGIN SOURCEDB msqldb@host1:3305, USERID ogg@ora1.ora, PASSWORD AACAAAAAAAAAAAJAUEUGODSCVGJEEIUGKJDJTFNDKEJFFFTC AES128, ENCRYPTKEY securekey1
Example 3
DBLOGIN SOURCEDB msqldb@host1:3305, USERID ogg@ora1.ora, PASSWORD
AACAAAAAAAJAIEUGODSCVGJEEIUUGKJDAJTFNDEJPFPTC AES128, ENCRYPTKEY securekey1,
SESSIONCHARSET ISO-8859-11

Example 4
DBLOGIN SOURCEDB pdb1 USERIDALIAS alias1 DOMAIN domain1

Example 5
DBLOGIN SOURCEDB pdb1 USERIDALIAS alias1 DOMAIN domain1 SYSDBA
ENCRYPT PASSWORD

Use ENCRYPT PASSWORD to encrypt a password that is used in an Oracle GoldenGate parameter file or command.

Syntax

ENCRYPT PASSWORD password
[AES128 | AES192 | AES256 | BLOWFISH]
ENCRYPTKEY {key_name | DEFAULT}

password
The login password. Do not enclose the password within quotes. If the password is
case-sensitive, type it that way.

AES128 | AES192 | AES256 | BLOWFISH
Specifies the encryption algorithm to use.

- AES128 uses the AES-128 cipher, which has a key size of 128 bits.
- AES192 uses the AES-192 cipher, which has a key size of 192 bits.
- AES256 uses the AES-256 cipher, which has a key size of 256 bits.
- BLOWFISH uses Blowfish encryption with a 64-bit block size and a variable-length
  key size from 32 bits to 128 bits. Use BLOWFISH only for backward compatibility
  with earlier Oracle GoldenGate versions.

If no algorithm is specified, AES128 is the default for all database types except DB2 on
z/OS and NonStop SQL/MX, where BLOWFISH is the default. AES is not supported for
those platforms.

All of the AES ciphers have a 128-bit block size.

To use AES encryption for any database other than Oracle, the path of the lib
sub-directory of the Oracle GoldenGate installation directory must be specified as an
environment variable before starting any processes:

- UNIX: Specify the path as an entry to the LD_LIBRARY_PATH or SHLIB_PATH
  variable. For example:
    setenv LD_LIBRARY_PATH ./lib:$LD_LIBRARY_PATH
- Windows: Add the path to the PATH variable.

You can use the SETENV parameter to set it as a session variable for the process.

ENCRYPTKEY {key_name | DEFAULT}
Specifies the encryption key.

key_name
Specifies the logical name of a user-created encryption key in a local ENCKEYS
lookup file. The key name is used to look up the actual key in the ENCKEYS file. A
user-created key and an associated ENCKEYS file is required when using AES
encryption; optional, but recommended, for Blowfish encryption. To use key_name,
generate the key with KEYSGEN or another utility, then store it in an ENCKEYS file on
the source and target systems. For more information, see the security guidelines in
the Administering Oracle GoldenGate for Windows and UNIX.
**DEFAULT**
Directs Oracle GoldenGate to generate a random key that is stored in the trail so that decryption can be performed by the downstream process. This type of key is insecure and should not be used in a production environment. Use this option only when BLOWFISH is specified. ENCRYPT PASSWORD returns an error if DEFAULT is used with any AES algorithm.

**Examples**

**Example 1**
```
ENCRYPT PASSWORD ny14072 BLOWFISH ENCRYPTKEY DEFAULT
```

**Example 2**
```
ENCRYPT PASSWORD ny14072 BLOWFISH ENCRYPTKEY superkey3
```

**Example 3**
```
ENCRYPT PASSWORD ny14072 AES192 ENCRYPTKEY superkey2
```
Use the DUMPDDL command to view the data in the Oracle GoldenGate DDL history table. This information is the same information that is used by the Extract process. It is stored in proprietary format, but can be exported in human-readable form to the screen or to a series of SQL tables that can be queried by using regular SQL.

DUMPDDL always dumps all of the records in the DDL history table. Use SQL queries or search redirected standard output to view information about particular objects and the operations you are interested in. Because the history table contains large amounts of data, only the first 4000 bytes (approximately) of a DDL statement are displayed in order to maintain efficient performance. The format of the metadata is string based. It is fully escaped and supports table and column names in their native character set.

Because the information is historical data that is provided by the DDL before trigger, it reflects the state of an object before a DDL change. Consequently, there will not be any data for CREATE operations.

---

**Note:** The default name of the before trigger is GGS_DDL_TRIGGER_BEFORE.

---

Before using DUMPDDL, log into the database as the owner of the history table by using the DBLOGIN command.

The basic DUMPDDL command outputs metadata to the following tables.

**Table 1–17  DUMPDDL Tables**

<table>
<thead>
<tr>
<th>Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GGS_DDL_OBJECTS</td>
<td>Information about the objects for which DDL operations are being synchronized. SEQNO is the primary key. All of the other tables listed here contain a SEQNO column that is the foreign key to GGS_DDL_OBJECTS.</td>
</tr>
<tr>
<td>GGS_DDL_COLUMNS</td>
<td>Information about the columns of the objects involved in DDL synchronization.</td>
</tr>
<tr>
<td>GGS_DDL_LOG_GROUPS</td>
<td>Information about the supplemental log groups involved in DDL synchronization.</td>
</tr>
<tr>
<td>GGS_DDL_PARTITIONS</td>
<td>Information about the partitions for objects involved in DDL synchronization.</td>
</tr>
<tr>
<td>GGS_DDL_PRIMARY_KEYS</td>
<td>Information about the primary keys of the objects involved in DDL synchronization.</td>
</tr>
</tbody>
</table>

The SEQNO column is the DDL sequence number that is listed in the Extract and Replicat report files. It also can be obtained by querying the DDL history table (default name is GGS_DDL_HIST).

All of these tables are owned by the schema that was designated as the Oracle GoldenGate DDL schema during the installation of the DDL objects. To view the structure of these tables, use the DESC command in SQL*Plus.

**Syntax**

DUMPDDL  [SHOW]
SHOW
Dumps the information contained in the history table to the screen in standard output format. No output tables are produced. All records in the DDL history table are shown.
FLUSH SEQUENCE

Use FLUSH SEQUENCE immediately after you start Extract for the first time during an initial synchronization or a re-synchronization. This command updates an Oracle sequence so that initial redo records are available at the time that Extract starts to capture transaction data. Normally, redo is not generated until the current cache is exhausted. The flush gives Replicat an initial start point with which to synchronize to the correct sequence value on the target system. From then on, Extract can use the redo that is associated with the usual cache reservation of sequence values.

To Use FLUSH SEQUENCE

1. The following Oracle procedures are used by FLUSH SEQUENCE:

<table>
<thead>
<tr>
<th>Database</th>
<th>Procedure</th>
<th>User and Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source</td>
<td>updateSequence</td>
<td>Grants EXECUTE to the owner of the Oracle GoldenGate DDL objects, or other selected user if not using DDL support.</td>
</tr>
<tr>
<td>Target</td>
<td>replicateSequence</td>
<td>Grants EXECUTE to the Oracle GoldenGate Replicat user.</td>
</tr>
</tbody>
</table>

The sequence.sql script installs these procedures. Normally, this script is run as part of the Oracle GoldenGate installation process, but make certain that was done before using FLUSH SEQUENCE. If sequence.sql was not run, the flush fails and an error message similar to the following is generated:

Cannot flush sequence {0}. Refer to the Oracle GoldenGate for Oracle documentation for instructions on how to set up and run the sequence.sql script. Error {1}.

2. The GLOBALS file must contain a GGSCHEMA parameter that specifies the schema in which the procedures are installed. This user must have CONNECT, RESOURCE, and DBA privileges.

3. Before using FLUSH SEQUENCE, issue the DBLOGIN command as the database user that has EXECUTE privilege on the updateSequence procedure. If logging into a multitentant container database, log into the pluggable database that contains the sequence that is to be flushed.

Note: For full instructions on configuring Oracle GoldenGate to support sequences, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Syntax

FLUSH SEQUENCE owner.sequence

owner.sequence
The owner and name of an Oracle sequence. The schema name cannot be null. You can use an asterisk (*) wildcard for the sequence name but not for the owner name.

Example

FLUSH SEQUENCE scott.seq*
LIST TABLES

Use LIST TABLES to list all tables in the database that match the specification provided with the command argument. Use the DBLOGIN command to establish a database connection before using this command. If logging into an Oracle multitentant container database, log in to the pluggable database that contains the tables that you want to list.

Syntax

LIST TABLES table

table
The name of a table or a group of tables specified with a wildcard (*).

Example

The following shows a LIST TABLES command and sample output.

list tables tcust*

TCUSTMER
TCUSTORD
**MININGDBLOGIN**

Use `MININGDBLOGIN` to establish a connection to a downstream Oracle database logmining server in preparation to issue other Oracle GoldenGate commands that affect this database, such as `REGISTER EXTRACT`. Use this command only if establishing Extract in integrated capture mode for an Oracle database.

To log into a source Oracle database that serves as the database logmining server, use the `DBLOGIN` command. `MININGDBLOGIN` is reserved for login to a downstream mining database.

The user who issues `MININGDBLOGIN` must:

- Have privileges granted through the Oracle `dbms_goldengate_auth.grant_admin_privilege` procedure.
- Be the user that is specified with the `TRANLOGOPTIONS MININGUSER` parameter for the Extract group that is associated with this `MININGDBLOGIN`.
- Not be changed while Extract is in integrated capture mode.

For support and configuration information for integrated capture, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

**Syntax**

```
MININGDBLOGIN {
    USERID {/ | userid}[, PASSWORD password]
        [algorithm ENCRYPTKEY {keyname | DEFAULT}] |
    USERIDALIAS alias [DOMAIN domain] |
    [SYSDBA]
}
```

**USERID**

Supplies a database login credential. Can be used if an Oracle GoldenGate credential store is not in use. (See the `USERIDALIAS` option.) Input varies, depending on the database, as follows:

`userid`

Specifies the name of a database user or a SQL*Net connect string. To log into a pluggable database in an Oracle multitenant container database, specify `userid` as a connect string, such as `OGGUSER@FINANCE`. To log into the root container, specify `userid` as a common user, including the C++ prefix, such as `C##GGADMIN@FINANCE`. For more information about configuring Oracle GoldenGate for a CDB, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

`/`

(Oracle) Directs Oracle GoldenGate to use an operating-system login for Oracle, not a database user login. Use this argument only if the database allows authentication at the operating-system level. To use this option, the correct user name must exist in the database, in relation to the value of the Oracle `OS_AUTHENT_PREFIX` initialization parameter. For more information, see the `USERID` parameter.

**PASSWORD password**

Use when authentication is required to specify the password for the database user. If the password was encrypted by means of the `ENCRYPT PASSWORD` command,
supply the encrypted password; otherwise, supply the clear-text password. If the password is case-sensitive, type it that way.

If the PASSWORD clause is omitted, you are prompted for a password, and the password is not echoed.

**algorithm**
If the password was encrypted with the ENCRYPT PASSWORD command, specify the encryption algorithm that was used:

- AES128
- AES192
- AES256
- BLOWFISH

**ENCRYPTKEY (keyname | DEFAULT)**
Specifies the encryption key that was specified with the ENCRYPT PASSWORD command. Use one of the following:

- ENCRYPTKEY keyname
  Specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if ENCRYPT PASSWORD was used with the KEYNAME keyname option.

- ENCRYPTKEY DEFAULT
  Directs Oracle GoldenGate to generate a Blowfish key. Use if the ENCRYPT PASSWORD command was used with the KEYNAME DEFAULT option.

**USERIDALIAS alias [DOMAIN domain]**
Supplies the alias of a database login credential. Can be used instead of the USERID option if there is a local Oracle GoldenGate credential store that contains a credential with the required privileges for this MININGDBLOGIN command. For more information about using a credential store, see Administering Oracle GoldenGate for Windows and UNIX.

To log into a pluggable database in an Oracle multitenant container database, the user must be stored as a connect string, such as OGGUSER@FINANCE. To log into the root container, the user must be stored as a common user, including the C++ prefix, such as C##GGADMIN@FINANCE. For more information about configuring Oracle GoldenGate for a CDB, see Installing and Configuring Oracle GoldenGate for Oracle Database.

- **alias**
  Specifies the alias of a database user credential that is stored in the Oracle GoldenGate credential store. The user that is specified with USERIDALIAS must be the common database user.

- **DOMAIN domain**
  Specifies the credential store domain for the specified alias. A valid domain entry must exist in the credential store for the specified alias.

**SYSDBA**
(Oracle) Specifies that the user logs in as sysdba. This option can be used for USERID and USERIDALIAS.
Examples

Example 1
MININGDBLOGIN USERID ogg@ora1.ora, PASSWORD
AACCAAAAAAAAJAEUX0DSCVGJEEIUGKJDJTFNDFKEJFFFTC AES128, ENCRYPTKEY securekey1

Example 2
MININGDBLOGIN SOURCEDB msqldb@host1:3305, USERID ogg@ora1.ora, PASSWORD
AACCAAAAAAAAJAEUX0DSCVGJEEIUGKJDJTFNDFKEJFFFTC AES128, ENCRYPTKEY securekey1

Example 3
MININGDBLOGIN SOURCEDB msqldb@host1:3305, USERID ogg@ora1.ora, PASSWORD
AACCAAAAAAAAJAEUX0DSCVGJEEIUGKJDJTFNDFKEJFFFTC AES128, ENCRYPTKEY securekey1,
SESSIONCHARSET ISO-8859-11

Example 4
MININGDBLOGIN SOURCEDB pdb1 USERIDALIAS alias1 DOMAIN domain1
SET NAMECCSID

Use NAMECCSID to set the CCSID (coded character set identifier) of the GGSCI session when you need to issue commands for tables in a DB2 for i database. This command is required if the CCSID of the object names stored in the SQL catalog tables is different from the CCSID of the system. The SQL catalog tables are created with the CCSID of the system, but the actual database object names could be represented with a different CCSID. The catalog does not indicate this difference when queried, and therefore Oracle GoldenGate could retrieve the name incorrectly unless NAMECCSID is present to supply the correct CCSID value.

To set the CCSID for GLOBALS, Extract, Replicat, or DEFGEN, use the NAMECCSID parameter.

SET NAMECCSID is not valid if the DBLOGIN command was previously issued, because that command affects the GGSCI session. To issue SET NAMECCSID after a DBLOGIN command, restart GGSCI.

To view the current CCSID, use the SHOW command. If the CCSID is not set through the GGSCI session or through the parameter NAMECCSID, the SHOW value will be DEFAULT.

Syntax

SET NAMECCSID {CCSID | DEFAULT}

CCSID
A valid DB2 for i coded character set identifier that is to be used for the GGSCI session.

DEFAULT
Indicates that the system CCSID is to be used for the GGSCI session.

Example

SET NAMECCSID 1141
**ADD SCHEMATRANDATA**

Valid for Oracle. Use **ADD SCHEMATRANDATA** to enable schema-level supplemental logging for a table. **ADD SCHEMATRANDATA** acts on all of the current and future tables in a given schema to automatically log a superset of available keys that Oracle GoldenGate needs for row identification.

**ADD SCHEMATRANDATA** is valid for both integrated and classic capture and does the following:

- Enables Oracle supplemental logging for new tables created with a `CREATE TABLE`.
- Updates supplemental logging for tables affected by an `ALTER TABLE` to add or drop columns.
- Updates supplemental logging for tables that are renamed.
- Updates supplemental logging for tables for which unique or primary keys are added or dropped.

By default, **ADD SCHEMATRANDATA** logs the key columns of a table in the following order of priority:

1. Primary key
2. In the absence of a primary key, all of the unique keys of the table, including those that are disabled, unusable or invisible. Unique keys that contain ADT member columns are also logged. Only unique keys on virtual columns (function-based indexes) are not logged.
3. If none of the preceding exists, all scalar columns of the table are logged. (System-generated row-OIDs are always logged.)

**ADD SCHEMATRANDATA** also supports the conditional or unconditional logging requirements for using integrated Replicat.

---

**Note:** Apply Oracle Patch 10423000 to the source database if the Oracle version is earlier than 11.2.0.2.

---

**When to Use ADD SCHEMATRANDATA**

**ADD SCHEMATRANDATA** must be used in the following cases:

- For all tables that are part of an Extract group that is to be configured for integrated capture. **ADD SCHEMATRANDATA** ensures that the correct key is logged by logging all of the keys.
- For all source tables that will be processed in an integrated Replicat group. Options are provided that enable the logging of the primary, unique, and foreign keys to support the computation of dependencies among relational tables being processed through different apply servers.
- When DDL replication is active and DML is concurrent with DDL that creates new tables or alters key columns. It best handles scenarios where DML can be applied to objects very shortly after DDL is issued on them. **ADD SCHEMATRANDATA** causes the appropriate key values to be logged in the redo log atomically with each DDL operation, thus ensuring metadata continuity for the DML when it is captured from the log, despite any lag in Extract processing.
Database-level Logging Requirements for Using ADD SCHEMATRANDATA
Oracle strongly encourages putting the source database into forced logging mode and enabling minimal supplemental logging at the database level when using Oracle GoldenGate. This adds row chaining information, if any exists, to the redo log for update operations. See *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about configuring logging to support Oracle GoldenGate.

Additional Considerations for Using ADD SCHEMATRANDATA

- Before using `ADD SCHEMATRANDATA`, issue the `DBLOGIN` command. The user who issues the command must be granted the Oracle Streams administrator privilege.
  ```sql
  SQL> exec dbms_streams_auth.grant_admin_privilege('user')
  ```

- `ADD SCHEMATRANDATA` can be used instead of the `ADD TRANDATA` command when DDL replication is not enabled. Note, however, that if a table has no primary key but has multiple unique keys, `ADD SCHEMATRANDATA` causes the database to log all of the unique keys. In such cases, `ADD SCHEMATRANDATA` causes the database to log more redo data than does `ADD TRANDATA`. To avoid the extra logging, designate one of the unique keys as a primary key, if possible.

- For tables with a primary key, with a single unique key, or without a key, `ADD SCHEMATRANDATA` adds no additional logging overhead, as compared to `ADD TRANDATA`. For more information, see "ADD TRANDATA" on page 1-133.

- If you must log additional, non-key columns of a specific table (or tables) for use by Oracle GoldenGate, such as those needed for `FILTER` statements and `KEYCOLS` clauses in the `TABLE` and `MAP` parameters, issue an `ADD TRANDATA` command for those columns. That command has a `COLS` option to issue table-level supplemental logging for the columns, and it can be used in conjunction with `ADD SCHEMATRANDATA`.

Syntax

```
ADD SCHEMATRANDATA schema {
[ALLOWNONVALIDATEDKEYS] [NOSCHEDULINGCOLS | ALLCOLS]}
```

`schema`

The schema for which you want the supplementary key information to be logged. Do not use a wildcard. To issue `ADD SCHEMATRANDATA` for schemas in more than one pluggable database of a multitenant container database, log in to each pluggable database separately with `DBLOGIN` and then issue `ADD SCHEMATRANDATA`. See `DBLOGIN` for more information.

`ALLOWNONVALIDATEDKEYS`

This option is valid for Oracle 11.2.0.4 and later 11g versions and Oracle 12.1.0.2 and later 12c versions. (Not valid for Oracle 11.2.0.3 or 12.1.0.1.) It includes `NON VALIDATED` and `NOT VALID` primary keys in the supplemental logging. These keys override the normal key selection criteria that is used by Oracle GoldenGate. If the `GLOBALS ALLOWNONVALIDATEDKEYS` parameter is being used, `ADD SCHEMATRANDATA` runs with `ALLOWNONVALIDATEDKEYS` whether or not it is specified. By default `NON VALIDATED` and `NOT VALID` primary keys are not logged. For more information, see the `GLOBALS ALLOWNONVALIDATEDKEYS` parameter.

`NOSCHEDULINGCOLS | ALLCOLS`

These options control supplemental logging for an Oracle target database. You can use these options together though the latter option is used. For example, with the `ADD
SCHEMATRANDATA oggadm_ext ALLCOL NOSCHEDULINGCOLS command the
NOSCHEDULINGCOLS option would be used.

NOSCHEDULINGCOLS
Disables the logging of scheduling columns. By default, ADD SCHEMATRANDATA
enables the unconditional logging of the primary key and the conditional
supplemental logging of all unique key(s) and foreign key(s) of all current and
future tables in the given schema. Unconditional logging forces the primary key
values to the log whether or not the key was changed in the current operation.
Conditional logging logs all of the column values of a foreign or unique key if at
least one of them was changed in the current operation. The integrated Replicat
primary key, unique keys, and foreign keys must all be available to the inbound
server to compute dependencies. For more information about integrated Replicat,
see Installing and Configuring Oracle GoldenGate for Oracle Database.

ALLCOLS
Enables the unconditional supplemental logging of all supported key and non-key
columns for all current and future tables in the given schema. This option enables
the logging of the keys required to compute dependencies, plus columns that are
required for filtering, conflict resolution, or other purposes. Columns like LOB,
LONG, and ADT are not included.

Example

Example 1
The following enables supplemental logging for the schema scott.
ADD SCHEMATRANDATA scott

Example 2
The following example logs all supported key and non-key columns for all current and
future tables in the schema named scott.
ADD SCHEMATRANDATA scott ALLCOLS
ADD TRANDATA

Use **ADD TRANDATA** to enable Oracle GoldenGate to acquire the transaction information that it needs from the transaction records.

Before using this command, use the **DBLOGIN** command to establish a database connection.

**ADD TRANDATA** is valid only for the databases that are listed here. For other supported databases, this functionality may exist already or must be configured through the database interface. See the Oracle GoldenGate installation guide for your database for any special requirements that apply to making transaction information available.

**DB2 for i** Databases

Use **ADD TRANDATA** to start the journaling of data. The **ADD TRANDATA** command calls **STRJRNPF** and is the recommended method to start journaling for tables, because it ensures that the required journal image attribute of Record Images (IMAGES): *BOTH is set on the **STRJRNPF** command.

**DB2 LUW Database**

Use **ADD TRANDATA** to enable **DATA CAPTURE CHANGES** on specified tables. By default, **ADD TRANDATA** issues the following command to the database:

```
ALTER TABLE name DATA CAPTURE CHANGES INCLUDE LONGVAR COLUMNS;
```

You can exclude the **LONGVAR** clause by using **ADD TRANDATA** with the **EXCLUDELONG** option.

**DB2 z/OS Database**

Use **ADD TRANDATA** to enable **DATA CAPTURE CHANGES** on specified tables. By default, **ADD TRANDATA** issues the following command to the database:

```
ALTER TABLE name DATA CAPTURE CHANGES;
```

**Oracle Database**

By default, **ADD TRANDATA** for Oracle enables the unconditional logging of the primary key and the conditional supplemental logging of all unique key(s) and foreign key(s) of the specified table. See *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about how Oracle GoldenGate handles supplemental logging for Oracle databases.

If possible, use the **ADD SCHEMATRANDATA** command rather than the **ADD TRANDATA** command. The **ADD SCHEMATRANDATA** command ensures replication continuity should DML occur on an object for which DDL has just been performed. You can exclude objects from the schema specification by using the exclusion parameters. See "Summary of Wildcard Exclusion Parameters" on page 3-12 for more information.

To use the Oracle GoldenGate DDL replication feature, you must use the **ADD SCHEMATRANDATA** command to log the required supplemental data.

When using **ADD SCHEMATRANDATA**, you can use **ADD TRANDATA** with the **COLS** option to log any non-key columns, such as those needed for **FILTER** statements and **KEYCOLS** clauses in the **TABLE** and **MAP** parameters.
Note: It is possible to use ADD TRANDATA for Oracle when DDL support is enabled, but only if you can stop DML on all tables before DDL is performed on them or, if that is not possible, you can guarantee that no users or applications will issue DDL that adds new tables whose names satisfy an object specification in a TABLE or MAP statement. There must be no possibility that users or applications will issue DDL that changes the key definitions of any tables that are already in the Oracle GoldenGate configuration.

For more information, see “ADD SCHEMATRANDATA” on page 1-130.

Oracle strongly encourages putting the source database into forced logging mode and enabling minimal supplemental logging at the database level when using Oracle GoldenGate. This adds row chaining information, if any exists, to the redo log for update operations. See Installing and Configuring Oracle GoldenGate for Oracle Database for more information about configuring logging to support Oracle GoldenGate.

Take the following into account when using ADD TRANDATA for an Oracle database:

- If any of the logging details change after Oracle GoldenGate starts extracting data, you must stop and then start the Extract process that is reading from the affected table before any data is changed.
- When creating a supplemental log group with ADD TRANDATA, Oracle GoldenGate appends the object ID to a prefix of GGS_, for example GGS_18342.

**SQL Server Database**

Use ADD TRANDATA to provide the extended logging information that Oracle GoldenGate needs to reconstruct SQL operations. The SQL Server transaction log does not provide enough information by default.

**Sybase Database**

ADD TRANDATA marks a Sybase table for replication by executing the Sybase sp_setreptable and sp_setrepcol system procedures. ADD TRANDATA options employ database features to control how the database propagates LOB data for the specified table. See the ADD TRANDATA options list.

**Syntax**

ADD TRANDATA {
  | [container.]owner.table | schema.table [JOURNAL library/journal] |
  | library/file [JOURNAL library/journal] |
  [, NOSCHEDULINGCOLS | ALLCOLS]
  [, COLS (columns)]
  [, INCLUDELONG | EXCLUDELONG]
  [, LOBSNEVER | LOBSALWAYS | LOBSIFCHANGED | LOBSALWAYSNOINDEX]
  [, NOKEY]
}

[container.]owner.table
Valid for DB2 LUW, DB2 for z/OS, Oracle, SQL Server, and Sybase.

The two-part or three-part name specification. Use a two-part name of owner.table for all supported databases except an Oracle multitentant container database. Use a three-part name of container.owner.table for an Oracle multitentant container database. A wildcard can be used for any component. Used with a wildcard, ADD TRANDATA filters out names that match the names of system objects. To use ADD TRANDATA for objects that are not system objects but have names that match those of
system objects in a wildcard pattern, issue ADD TRANDATA for those objects without using a wildcard.

```
  schema.table [JOURNAL library/journal] |
  library/file [JOURNAL library/journal]
```

Valid for DB2 for i.

Specifies the SQL schema and name of a table or the native library and file name. If a default journal is set with the DEFAULTJOURNAL command, you can omit the JOURNAL option; otherwise it is required.

**NOSCHEDULINGCOLS | ALLCOLS**

Valid for Oracle

These options satisfy the logging requirements of an integrated Replicat that will be processing the tables that you are specifying with ADD TRANDATA.

**NOSCHEDULINGCOLS**

Disables the logging of scheduling columns. By default, ADD TRANDATA enables the unconditional logging of the primary key and the conditional supplemental logging of all unique key(s) and foreign key(s) of the specified table. Unconditional logging forces the primary key values to the log whether or not the key was changed in the current operation. Conditional logging logs all of the column values of a foreign or unique key if at least one of them was changed in the current operation. The primary key, unique keys, and foreign keys must all be available to the inbound server to compute dependencies. For more information about integrated Replicat, see Installing and Configuring Oracle GoldenGate for Oracle Database.

**ALLCOLS**

Enables the unconditional supplemental logging of all of the key and non-key columns of the table. This option enables the logging of the keys required to compute dependencies, plus all other columns for use in filtering, conflict resolution, or other purposes.

**COLS (columns)**

Valid for all databases supported by ADD TRANDATA.

Use the COLS option to log specific non-key columns. Can be used to log columns specified in a KEYCOLS clause and to log columns that will be needed for filtering or manipulation purposes, which might be more efficient than fetching those values with a FETCHCOLS clause in a TABLE statement. Separate multiple columns with commas, for example NAME, ID, DOB.

**INCLUDELONG | EXCLUDELONG**

Valid for DB2 LUW.

Controls whether or not the ALTER TABLE issued by ADD TRANDATA includes the INCLUDE LONGVAR COLUMNS attribute. INCLUDELONG is the default. When ADD TRANDATA is issued with this option, Oracle GoldenGate issues the following statement:

```
  ALTER TABLE name DATA CAPTURE CHANGES INCLUDE LONGVAR COLUMNS;
```

When EXCLUDELONG is used, the following is the command:

```
  ALTER TABLE name DATA CAPTURE CHANGES;
```
When `EXCLUDELONG` is used, Oracle GoldenGate does not support functionality that requires before images of tables that include `LONGVAR` columns. Examples of this functionality are the `GETUPDATEBEFORES`, `NOCOMPRESSUPDATES`, and `NOCOMPRESSDELETES` parameters. To support this functionality, changes to `LONGVAR` columns in the transaction logs must include both the before and after images of the column value.

**LOBSNEVER | LOBSALWAYS | LOBSIFCHANGED | LOBSALWAYSNOINDEX**

Valid for Sybase.

Controls how the database propagates LOB data for the specified table.

---

**Note:** The `ADD TRANDATA` command will overwrite the LOB setting that is currently set for the table. To change the setting afterwards, you must use the `sp_setrepcol` script.

---

**LOBSNEVER**

Prevents LOB data from being propagated. Note this exception: If the LOB column is inserted with a `NULL` value, or if it is skipped in an `INSERT` operation, then Extract will write that column to the trail with `NULL` data.

**LOBSALWAYS**

Does two things: it uses `sp_setrepcol` to set LOB replication to `ALWAYS_REPLICATE` (always replicate LOB data whether or not it has changed in a transaction), and it marks the table to use an index on replication (by means of the `USE_INDEX` option of `sp_setreptable`). Because a LOB is marked for replication in a single transaction, this can take a long time, and `USE_INDEX` reduces that time by creating a global nonclustered index for every LOB. A shared-table lock is held while the global nonclustered index is created.

**LOBSIFCHANGED**

Replicates LOB data only if it was changed during a transaction. This reduces replication overhead but does not protect against inconsistencies that could occur on the target outside the replication environment. This is the default.

**LOBSALWAYSNOINDEX**

Sets LOB replication to `ALWAYS_REPLICATE` (always replicate LOB data whether or not it has changed in a transaction). This adds overhead, but protects against inconsistencies that could occur on the target outside the replication environment. `LOBSALWAYSNOINDEX` does not mark the table to use an index on replication. The benefit is that no lock is held while `ADD TRANDATA` is being executed. `LOBSALWAYSNOINDEX` is the default for Sybase databases earlier than version 15.

---

**Note:** When using the `ALWAYS_REPLICATE` option, if a LOB column contains a `NULL` value, and then another column in the table gets updated (but not the LOB), that LOB will not be captured even though `ALWAYS_REPLICATE` is enabled.

---

You can check the LOB settings of a table with the `INFO TRANDATA` command, after `ADD TRANDATA` has been used for that table. It shows the LOB settings for all of the LOB columns. You can use the Sybase system procedures to change the LOB settings for any given column as needed.

**NOKEY**

Valid for all databases supported by `ADD TRANDATA`. 

---
Suppresses the supplemental logging of primary key columns. If using NOKEY, use the COLS option to log alternate columns that can serve as keys, and designate those columns as substitute keys by using the KEYCOLS option of the TABLE or MAP parameter.

**Examples**

**Example 1**
The following example causes one of the following: the primary key to be logged for an Oracle table; supplemental data to be logged for a SQL Server table; or a Sybase table to be marked for replication.

```
ADD TRANDATA finance.acct
```

**Example 2**
The following example enables the unconditional supplemental logging of all of the key and non-key columns for the table named acct.

```
ADD TRANDATA acct ALLCOLS
```

**Example 3**
The following Oracle example causes the primary key to be logged plus the non-key columns name and address.

```
ADD TRANDATA finance.acct, COLS (name, address)
```

**Example 4**
The following Oracle example prevents the primary key from being logged, but logs the non-key columns name and pid instead.

```
ADD TRANDATA finance.acct, NOKEY, COLS (name, pid)
```

**Example 5**
The following Sybase example marks the acct table for replication and specifies to log LOB data only if it was changed during a transaction.

```
ADD TRANDATA finance.acct, LOBSIFCHANGED
```

**Example 6**
The following example enables the any in-flight transactions to be finished and acquires a lock on the interested table object, acct.

```
ADD TRANDATA acct PREPARECSN(LOCK)
```
DELETE SCHEMATRANDATA

Use DELETE SCHEMATRANDATA to remove the Oracle schema-level supplemental logging that was added with the ADD SCHEMATRANDATA command. Use the DBLOGIN command to establish a database connection before using this command. The user that is specified with this command must have the privilege to remove supplemental log groups.

By default, this command attempts to remove the supplemental logging of the key columns that are used by Oracle GoldenGate (can be the primary key, a unique key, KEYCOLS columns, or all columns) and also the scheduling columns. The scheduling columns are the primary key, all of the unique keys, and all of the foreign keys. To delete the logging of the Oracle GoldenGate key columns, but not the scheduling columns, include the NOSCHEDULINGCOLS option with DELETE SCHEMATRANDATA. If ADD SCHEMATRANDATA was issued with the ALLCOLS option, use DELETE SCHEMATRANDATA with the ALLCOLS option to remove the supplemental logging of all of the columns, including the Oracle GoldenGate key columns.

Syntax

DELETE SCHEMATRANDATA schema [NOSCHEDULINGCOLS | ALLCOLS]

schema
The schema for which you want supplemental logging to be removed. Do not use a wildcard. If the source is an Oracle multitentant container database, make certain to log into the pluggable database that contains the schema for which you want to remove the logging. See DBLOGIN for more information.

NOSCHEDULINGCOLS
Prevents the command from removing the supplemental logging of the scheduling columns of the tables in the specified schema. The scheduling columns are the primary key, all of the unique keys, and all of the foreign keys of a table.

ALLCOLS
Removes the supplemental logging of all of the columns of the tables in the specified schema.

Examples

Example 1
DELETE SCHEMATRANDATA scott

Example 2
DELETE SCHEMATRANDATA scott ALLCOLS
DELETE TRANDATA

Use `DELETE TRANDATA` to do one of the following:

- DB2 LUW and DB2 on z/OS: Alters the table to `DATA CAPTURE NONE`.
- Oracle: Disable supplemental logging.
- Sybase: Disable replication.
- SQL Server: Stop extended logging.

By default, this command attempts to remove the supplemental logging of the key columns that are used by Oracle GoldenGate (can be the primary key, a unique key, `KEYCOLS` columns, or all columns) and also the scheduling columns. The scheduling columns are the primary key, all of the unique keys, and all of the foreign keys. To delete the logging of the Oracle GoldenGate key columns, but not the scheduling columns, include the `NOSCHEDULINGCOLS` option with `DELETE TRANDATA`. If `ADD TRANDATA` was issued with the `ALLCOLS` option, use `DELETE TRANDATA` with the `ALLCOLS` option to remove the supplemental logging of all of the columns, including the Oracle GoldenGate key columns.

Use the `DBLOGIN` command to establish a database connection before using this command. The user specified with this command must have the same privileges that are required for `ADD TRANDATA`.

**Syntax**

```bash
DELETE TRANDATA [container.]owner.table [NOSCHEDULINGCOLS | ALLCOLS]
```

`[container.]owner.table`

The pluggable database (if this is an Oracle multitentant container database), owner and name of the table or file. A wildcard can be used for any name component.

`NOSCHEDULINGCOLS`

Prevents the command from removing the supplemental logging of the scheduling columns of the specified table. The scheduling columns are the primary key, all of the unique keys, and all of the foreign keys of a table.

`ALLCOLS`

Removes the supplemental logging of all of the columns of the specified table.

**Examples**

**Example 1**

`DELETE TRANDATA finance.acct`

**Example 2**

`DELETE TRANDATA finance.ac*t`

**Example 3**

`DELETE TRANDATA finance.acct ALLCOLS`
Use **INFO SCHEMATRANDATA** to determine whether Oracle schema-level supplemental logging is enabled for the specified schema. Use the **DBLOGIN** command to establish a database connection before using this command.

**Syntax**

```
INFO SCHEMATRANDATA schema
```

*schema*

The schema for which you want to confirm supplemental logging. Do not use a wildcard. To get information on the appropriate schema in an Oracle multitentant container database, make certain to log into the correct pluggable database with **DBLOGIN**.

**Example**

```
INFO SCHEMATRANDATA scott
```
INFO TRANDATA

Use **INFO TRANDATA** to get the following information:

- **DB2 LUW and DB2 on z/OS**: Determine whether **DATA CAPTURE** is enabled or not.
- **Oracle**: Determine whether supplemental logging is enabled, and to show the names of columns that are being logged supplementally. If all columns are being logged, the notation **ALL** is displayed instead of individual column names.
- **Sybase**: Determine whether replication is enabled or not, and whether all LOB columns have identical logging settings (as specified with the **ADD TRANDATA LOB** options).
- **SQL Server**: Determine whether or not extended logging is enabled.

Use the **DBLOGIN** command to establish a database connection before using this command.

**Syntax**

```
INFO TRANDATA [container.]owner.table

[container.]owner.table
```

The pluggable database (if this is an Oracle multitentant container database), owner and name of the table or file for which you want to view trandata information. The owner is not required if it is the same as the login name that was specified by the **DBLOGIN** command. A wildcard can be used for the table name but not the owner name.

**Examples**

**Example 1**

```
INFO TRANDATA finance.acct
```

**Example 2**

```
INFO TRANDATA finance.ac*
```
ADD CHECKPOINTTABLE

Use ADD CHECKPOINTTABLE to create a checkpoint table in the target database. Replicat uses the table to maintain a record of its read position in the trail for recovery purposes.

The use of a checkpoint table is strongly recommended, because it causes checkpoints to be part of the Replicat transaction. This allows Replicat to recover more easily in certain circumstances than when a checkpoint file alone is used. However, do not use a checkpoint table when configuring Replicat to operate in integrated mode against an Oracle target database. It is not required in that mode.

One table can serve as the default checkpoint table for all Replicat groups in an Oracle GoldenGate instance if you specify it with the CHECKPOINTTABLE parameter in a GLOBALS file. More than one instance of Oracle GoldenGate (multiple installations) can use the same checkpoint table. Oracle GoldenGate keeps track of the checkpoints even when the same Replicat group name exists in different instances.

Use the DBLOGIN command to establish a database connection before using this command. Do not change the names or attributes of the columns in this table. You may, however, change table storage attributes.

For more information about using a checkpoint table, see Administering Oracle GoldenGate for Windows and UNIX.

See Administering Oracle GoldenGate for Windows and UNIX for more information about checkpoints.

Syntax

ADD CHECKPOINTTABLE [[container. | catalog.]owner.table]

container. | catalog.
The Oracle pluggable database or SQL/MX catalog, if applicable. If this option is omitted, the catalog or pluggable database defaults to the one that is associated with the SOURCEDB, USERID, or USERIDALIAS portion of the DBLOGIN command (depending on the database).

owner.table
The owner and name of the checkpoint table to be created. The name cannot contain any special characters, such as quotes, backslash, dollar sign, and percent symbol. The name of a MySQL checkpoint table can contain no more than 30 characters.

The owner and name can be omitted if you are using this table as the default checkpoint table and it is listed with CHECKPOINTTABLE in the GLOBALS file.

It is recommended, but not required, that the table be created in a schema dedicated to Oracle GoldenGate. If an owner and name are not specified, a default table is created based on the CHECKPOINTTABLE parameter in the GLOBALS parameter file.

Record the name of the table, because you will need it to view statistics or delete the table if needed.
Examples

Example 1
The following adds a checkpoint table with the default name specified in the `GLOBALS` file.

```
ADD CHECKPOINTTABLE
```

Example 2
The following adds a checkpoint table with a user-defined name.

```
ADD CHECKPOINTTABLE ggs.fin_check
```
CLEANUP CHECKPOINTTABLE

Use CLEANUP CHECKPOINTTABLE to remove checkpoint records from the checkpoint table when there is no checkpoint file associated with it in the working Oracle GoldenGate directory (from which GGSCI was started). The purpose of this command is to remove checkpoint records that are not needed any more, either because groups were changed or files were moved.

Use the DBLOGIN command to establish a database connection before using this command.

Syntax

CLEANUP CHECKPOINTTABLE [[container. | catalog.]|owner.table]

container. | catalog.
The Oracle pluggable database or SQL/MX catalog, if applicable. If this option is omitted, the catalog or pluggable database defaults to the one that is associated with the SOURCEDB, USERID, or USERIDALIAS portion of the DBLOGIN command (depending on the database).

owner.table
The owner and name of the checkpoint table to be cleaned up. If an owner and name are not specified, the table that is affected is the one specified with the CHECKPOINTTABLE parameter in theGLOBALS parameter file.

Example

CLEANUP CHECKPOINTTABLE ggs.fin_check
DELETE CHECKPOINTTABLE

Use DELETE CHECKPOINTTABLE to drop a checkpoint table from the database. Use the DBLOGIN command to establish a database connection before using this command.

To stop using a checkpoint table while the associated Replicat group remains active, follow these steps:

1. Run GGSCI.
2. Stop Replicat.
   STOP REPLICAT group
3. Delete the Replicat group and then add it back with the following commands.
   DELETE REPLICAT group
   ADD REPLICAT group, EXTRAIL trail, NODBCHECKPOINT
4. Exit GGSCI, then start it again.
5. Start Replicat again.
   START REPLICAT group
6. Log into the database with the DBLOGIN command, using the appropriate authentication options for the database. See "DBLOGIN" on page 1-116.
7. Delete the checkpoint table with DELETE CHECKPOINTTABLE.

If the checkpoint table is deleted while Replicat is still running and transactions are occurring, Replicat will abend with an error that the checkpoint table could not be found. However, the checkpoints are still maintained on disk in the checkpoint file. To resume processing, add the checkpoint table back under the same name. Data in the trail resumes replicating. Then, you can delete the checkpoint table.

Syntax

DELETE CHECKPOINTTABLE [([container | catalog]owner.table) | !]

container | catalog.
The Oracle pluggable database or SQL/MX catalog, if applicable. If this option is omitted, the catalog or pluggable database defaults to the one that is associated with the SOURCEDB, USERID, or USERIDALIAS portion (depending on the database) of the DBLOGIN command.

owner.table
The owner and name of the checkpoint table to be deleted. An owner and name are not required if they are the same as those specified with the CHECKPOINTTABLE parameter in the GLOBALS file.

!
Bypasses the prompt that confirms intent to delete the table.

Example

DELETE CHECKPOINTTABLE ggs.fin_check
Use INFO CHECKPOINTTABLE to confirm the existence of a checkpoint table and view the date and time that it was created. It returns a message similar to the following:

Use the DBLOGIN command to establish a database connection before using this command.

Syntax

```
INFO CHECKPOINTTABLE [[container. | catalog.]owner.table]
```

**container. | catalog.**
The Oracle pluggable database or SQL/MX catalog, if applicable. If this option is omitted, the catalog or pluggable database defaults to the one that is associated with the SOURCEDB, USERID, or USERIDALIAS portion of the DBLOGIN command (depending on the database).

**owner.table**
The owner and name of the checkpoint table. An owner and name are not required if they are the same as those specified with the CHECKPOINTTABLE parameter in the GLOBALS file.

Example

```
INFO CHECKPOINTTABLE ggs.fin_check
```
Use the `UPGRADE CHECKPOINTTABLE` command to add a supplemental checkpoint table when upgrading Oracle GoldenGate from version 11.2.1.0.0 or earlier.

**Syntax**

```
UPGRADE CHECKPOINTTABLE [container. | catalog.]owner.table
```

*container. | catalog.*
The Oracle pluggable database or SQL/MX catalog, if applicable. If this option is omitted, the catalog or pluggable database defaults to the one that is associated with the `SOURCEDB`, `USERID`, or `USERIDALIAS` portion of the `DBLOGIN` command (depending on the database).

*owner.table*
The owner and name of the checkpoint table. An owner and name are not required if they are the same as those specified with the `CHECKPOINTTABLE` parameter in the `GLOBALS` file.

**Example**

```
UPGRADE CHECKPOINTTABLE ggs.fin_check
```
ADD TRACETABLE

Use **ADD TRACETABLE** to create a trace table in the Oracle database. The trace table must reside in the schema of the Oracle GoldenGate Extract user, as configured with the **USERID** or **USERIDALIAS** parameter. The trace table prevents Replicat transactions from being extracted again in a bidirectional synchronization configuration.

Use the **DBLOGIN** command to establish a database connection before using this command.

The trace table has the following description.

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP_ID</td>
<td>NOT NULL</td>
<td>VARCHAR2(8)</td>
<td>The name of the Replicat group or special run process.</td>
</tr>
<tr>
<td>DB_USER</td>
<td></td>
<td>VARCHAR2(30)</td>
<td>The user ID of the Replicat group or special run process.</td>
</tr>
<tr>
<td>LAST_UPDATE</td>
<td></td>
<td>DATE</td>
<td>The timestamp of the transaction.</td>
</tr>
</tbody>
</table>

**Syntax**

```sql
ADD TRACETABLE [(container.)owner.table]
```

*container*  
The pluggable database, if the database is a multitenant container database (CDB).

*owner.table*  
Optional, use only to specify a trace table with a name that is different from the default of **GGS_TRACE**. The owner must be the same owner that is specified with the **USERID** or **USERIDALIAS** parameter in the Extract parameter file.

To use the default name, omit this argument. Whenever possible, use the default table name. When using a trace table name other than the default of **GGS_TRACE**, specify it with the **TRACETABLE** parameter in the Extract and Replicat parameter files. Record the name, because you will need it for the parameter files and to view statistics or delete the table. For more information, see "**TRACETABLE | NOTRACETABLE**" on page 3-357.

**Examples**

**Example 1**
The following adds a trace table with the default name of **GGS_TRACE**.

```sql
ADD TRACETABLE
```

**Example 2**
The following adds a trace table with a user-defined name of **ora_trace**.

```sql
ADD TRACETABLE ora_trace
```
DELETE TRACETABLE

Use DELETE TRACETABLE to delete a trace table. Use the DBLOGIN command to establish a database connection before using this command.

Syntax

DELETE TRACETABLE [[container.]owner.table]

container
The pluggable database, if the database is a multitentant container database (CDB).

owner.table
The owner and name of the trace table to be deleted. An owner and name are not required if the owner is the same as that specified with the USERID or USERIDALIAS parameter and the trace table has the default name of GGS_TRACE.

Example

DELETE TRACETABLE ora_trace
INFO TRACETABLE

Use the INFO TRACETABLE command to verify the existence of the specified trace table in the local instance of the database. If the table exists, Oracle GoldenGate displays the name and the date and time that it was created; otherwise Oracle GoldenGate displays a message stating that the table does not exist. Use the DBLOGIN command to establish a database connection before using this command.

Syntax

INFO TRACETABLE [[container.]owner.table]

container
The pluggable database, if the database is a multitentant container database (CDB).

owner.table
The owner and name of the trace table to be verified. An owner and name are not required if the owner is the same as that specified with the USERID or USERIDALIAS parameter and the trace table has the default name of GGS_TRACE.

Example

INFO TRACETABLE ora_trace
ALTER DATASTORE

Use the ALTER DATASTORE command to change the memory model that is used for interprocess communication by the Oracle GoldenGate Monitor data store. Before using this command, stop all Oracle GoldenGate processes, including Manager. See Administering Oracle GoldenGate Monitor for more information about the data store.

Syntax

ALTER DATASTORE {MMAP | SHM [ID n]}

MMAP
Indicates that the data store should use memory mapped files for interprocess communications.

SHM [ID n]
Indicates that the data store should use System V shared memory for interprocess communications. This option is not available on Windows platforms. If ID is not specified, a suitable default ID is used.

Examples

Example 1
ALTER DATASTORE MMAP

Example 2
ALTER DATASTORE SHM

Example 3
ALTER DATASTORE SHM ID 1000
CREATE DATASTORE

Use the CREATE DATASTORE command to create an Oracle GoldenGate Monitor datastore in the Oracle GoldenGate installation directory. For more information, see Administering Oracle GoldenGate Monitor.

Syntax

CREATE DATASTORE [ MMAP | SHM [ID n] ]

MMAP
Indicates that the data store should use memory mapped files for interprocess communications.

SHM [ID n]
Indicates that the data store should use System V shared memory for interprocess communications. This option is not available on Windows platforms. If ID is not specified, a suitable default ID is used. SHM is the default.

Examples

Example 1
CREATE DATASTORE MMAP

Example 2
CREATE DATASTORE SHM

Example 3
CREATE DATASTORE SHM ID 1000
DELETE DATASTORE

Use the DELETE DATASTORE command to remove the Oracle GoldenGate Monitor data store from the Oracle GoldenGate installation directory. Before using this command, stop all Oracle GoldenGate processes, including Manager. For more information, see Administering Oracle GoldenGate Monitor.

Syntax

DELETE DATASTORE [ ! ]

!  
(Exclamation point character) Bypasses the prompt that confirms the intent to remove the data store.

Examples

Example 1
DELETE DATASTORE

Example 2
DELETE DATASTORE !
Use the INFO DATASTORE command to display information about the Oracle GoldenGate Monitor data store. For more information, see Administering Oracle GoldenGate Monitor.

Syntax

INFO DATASTORE
**REPAIR DATASTORE**

Use the `REPAIR DATASTORE` command to repair the Oracle GoldenGate Monitor data store if it is corrupt or after an upgrade.

Before using this command, stop all Oracle GoldenGate processes, including Manager. For more information, see *Administering Oracle GoldenGate Monitor*.

**Syntax**

```
REPAIR DATASTORE
```
Use the `INFO JAGENT` command to determine whether or not the Oracle GoldenGate Monitor JAgent is running. This command is an alias for `STATUS JAGENT`. For more information, see *Administering Oracle GoldenGate Monitor*.

**Syntax**

```
INFO JAGENT
```
START JAGENT

Use the START JAGENT command to start the Oracle GoldenGate Monitor JAgent process in a non-clustered environment. In a Windows cluster, start JAgent from the Cluster Administrator. For more information, see Administering Oracle GoldenGate Monitor.

Syntax

START JAGENT
STATUS JAGENT

Use the STATUS JAGENT command to determine whether or not the Oracle GoldenGate Monitor JAgent is running. This command is an alias for INFO JAGENT. For more information, see Administering Oracle GoldenGate Monitor.

Syntax

STATUS JAGENT
Use the `STOP JAGENT` command to stop the Oracle GoldenGate Monitor JAgent process in a non-clustered environment. In a Windows cluster, stop JAgent from the Cluster Administrator. For more information, see *Administering Oracle GoldenGate Monitor*.

**Syntax**

```
STOP JAGENT [ ! ]
```

!  
(Exclamation point character) Bypasses the prompt that confirms the intent to stop the JAgent.

**Examples**

**Example 1**

```
STOP JAGENT
```

**Example 2**

```
STOP JAGENT !
```
Use the ! command to execute a previous GGSCI command without modifications. To modify a command before executing it again, use the FC command (see "FC" on page 1-164). To display a list of previous commands, use the HISTORY command (see "HISTORY" on page 1-167).

The ! command without arguments executes the most recent command. Options enable you to execute any previous command by specifying its line number or a text substring. Previous commands can be executed again only if they were issued during the current session of GGSCI, because command history is not maintained from session to session.

### Syntax

```
! [n | -n | string]
```

- `n` Executes the command from the specified GGSCI line. Each GGSCI command line is sequenced, beginning with 1 at the start of the session.
- `-n` Executes the command issued `n` lines before the current line.
- `string` Executes the last command that starts with the specified text string.

### Examples

**Example 1**

```
! 9
```

**Example 2**

```
! -3
```

**Example 3**

```
! sta
```
ALLOWNESTED | NOALLOWNESTED

Use the ALLOWNESTED and NOALLOWNESTED commands to enable or disable the use of nested OBEY files. A nested OBEY file is one that contains another OBEY file.

When you exit your GGSCI session, the next GGSCI session will revert back to NOALLOWNESTED.

For more information, see "OBEY" on page 1-170.

Syntax

ALLOWNESTED | NOALLOWNESTED

ALLOWNESTED
Enables the use of nested OBEY files. The maximum number of nested levels is 16.

NOALLOWNESTED
This is the default. An attempt to run a nested OBEY file in the default mode of NOALLOWNESTED will cause an error that is similar to the following:

ERROR: Nested OBEY scripts not allowed. Use ALLOWNESTED to allow nested scripts.
CREATE SUBDIRS

Use CREATE SUBDIRS when installing Oracle GoldenGate. This command creates the default directories within the Oracle GoldenGate home directory. Use CREATE SUBDIRS before any other configuration tasks.

Syntax

CREATE SUBDIRS
DEFAULTJOURNAL

Use the DEFAULTJOURNAL command to set a default journal for multiple tables or files for the ADD TRANDATA command when used with a DB2 for i database, instead of having to use the JOURNAL keyword. Issue this command before issuing ADD TRANDATA. Any ADD TRANDATA command used without a journal assumes the journal from DEFAULTJOURNAL. To remove the use of a default journal, use the CLEAR option. To display the current setting of DEFAULTJOURNAL, you can issue the command without arguments.

Syntax

DEFAULTJOURNAL [library/journal] [CLEAR]

library/journal
The native name of the journal that you want to use as the default journal for ADD TRANDATA.

CLEAR
Stops the use of a default journal for ADD TRANDATA.
Use `FC` to display edit a previously issued GGSCI command and then execute it again. Previous commands are stored in the memory buffer and can be displayed by issuing the `HISTORY` command (see "HISTORY" on page 1-167).

**Displaying Previous Commands**
Issuing `FC` without arguments displays the most recent command. Options enable you to execute any previous command by specifying its line number or a text substring. Previous commands can be edited only if they were issued during the current GGSCI session, because history is not maintained from one session to another.

**Editing Commands**
The `FC` command displays the specified command and then opens an editor with a prompt containing a blank line starting with two dots. To edit a command, use the space bar to position the cursor beneath the character in the displayed command where you want to begin editing, and then use one of the following arguments. Arguments are not case-sensitive and can be combined.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
</table>
| `i text` | Inserts text. For example:  
  GGSCI (SysA) 24> fc 9  
  GGSCI (SysA) 24> send mgr  
  GGSCI (SysA) 24.. i childstatus  
  GGSCI (SysA) 24> send mgr childstatus |
| `r text` | Replaces text. For example:  
  GGSCI (SysA) 25> fc 9  
  GGSCI (SysA) 25> info mgr  
  GGSCI (SysA) 25.. rextract extjd  
  GGSCI (SysA) 25> info extract extjd |
| `d` | Deletes a character. To delete multiple characters, enter a `d` for each one. For example:  
  GGSCI (SysA) 26> fc 10  
  GGSCI (SysA) 26> info extract extjd, detail  
  GGSCI (SysA) 26.. dddddddd  
  GGSCI (SysA) 26> info extract extjd |
| `replacement text` | Replaces the displayed command with the text that you enter on a one-for-one basis. For example:  
  GGSCI (SysA) 26> fc 10  
  GGSCI (SysA) 26> info mgr  
  GGSCI (SysA) 26.. extract extjd  
  GGSCI (SysA) 26> info extract extjd |

To execute the command, press **Enter** twice, once to exit the editor and once to issue the command. To cancel an edit, type a forward slash (/) twice.

**Syntax**

```
FC [n | -n | string]
```
n
Displays the command from the specified line. Each GGSCI command line is sequenced, beginning with 1 at the start of the session.

-n
Displays the command that was issued \(n\) lines before the current line.

string
Displays the last command that starts with the specified text string.

Examples

Example 1
FC 9

Example 2
FC -3

Example 3
FC sta
HELP

Use HELP to obtain information about an Oracle GoldenGate command. The basic command returns a list of command categories and the associated commands. The command option restricts the output to that of a specific command.

Syntax

HELP [command]

command
The command for which you want help.

Example

HELP add replicat
Use HISTORY to view a list of the most recently issued GGSCI commands since the startup of the GGSCI session. You can use the ! command ("!" on page 1-160) or the FC command ("FC" on page 1-164) to re-execute a command in the list.

Syntax

HISTORY [n]

n
Returns a specific number of recent commands, where n is any positive number.

Example

HISTORY 7
The result of this command would be similar to:

1: start manager
2: status manager
3: info manager
4: send manager childstatus
5: start extract extjd
6: info extract extjd
7: history
INFO ALL

Use **INFO ALL** to display the status and lag (where relevant) for all Manager, Extract, and Replicat processes on a system. The basic command, without options, displays only online (continuous) processes. To display tasks, use either **INFO ALL TASKS** or **INFO ALL ALLPROCESSES**.

The **Status** and **Lag at Chkpt** (checkpoint) fields display the same process status and lag as the **INFO EXTRACT** and **INFO REPLICAT** commands.

If Replicat is in coordinated mode, **INFO ALL** shows only the coordinator thread. To view information about individual threads, use **INFO REPLICAT**.

### Example 1–1  Sample INFO ALL Output

<table>
<thead>
<tr>
<th>Program</th>
<th>Status</th>
<th>Group</th>
<th>Lag at Chkpt</th>
<th>Time Since Chkpt</th>
</tr>
</thead>
<tbody>
<tr>
<td>MANAGER</td>
<td>RUNNING</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EXTRACT</td>
<td>ABENDED</td>
<td>EXTCUST</td>
<td>00:00:00</td>
<td>96:56:14</td>
</tr>
<tr>
<td>EXTRACT</td>
<td>STOPPED</td>
<td>INITDL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EXTRACT</td>
<td>STOPPED</td>
<td>INITDBL</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Syntax**

**INFO ALL** [**TASKS** | **ALLPROCESSES**]

**TASKS**
Displays information only for tasks.

**ALLPROCESSES**
Displays information for online processes and tasks.

**Examples**

**Example 1**

INFO ALL TASKS

**Example 2**

INFO ALL ALLPROCESSES
INFO MARKER

Use `INFO MARKER` to review recently processed markers from a NonStop system. A record is displayed for each occasion on which GGSCI, Logger, Extract, or Replicat processed the marker.

Markers can only be added on a NonStop system, using Oracle GoldenGate for NonStop for HP NonStop software.

The following is an example of the output.

<table>
<thead>
<tr>
<th>Processed</th>
<th>Added</th>
<th>Diff</th>
<th>Prog</th>
<th>Group</th>
<th>Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-02-16:14:41:15</td>
<td>2012-02-16:14:41:08</td>
<td>00:00:07</td>
<td>Extract</td>
<td>PQACMD</td>
<td>\QAMD GROUPCMD REPLICAT RQACMD CLOSEFILES</td>
</tr>
<tr>
<td>2012-02-16:14:41:13</td>
<td>2012-02-16:14:41:08</td>
<td>00:00:05</td>
<td>Extract</td>
<td>PQACMD</td>
<td>\QAMD TACLCMD REPLICAT RQACMD FUP PURGEDATA $QA16.QAETAR</td>
</tr>
</tbody>
</table>

Where:
- **Processed** is the local time that a program processed the marker.
- **Added** is the local time at which the marker was inserted into the NonStop audit trails or log trails.
- **Diff** is the time difference between the `Processed` and `Added` values. `Diff` can serve as an indicator of the lag between the user application and Extract and Replicat activities.
- **Prog** shows which process processed the marker, such as GGSCI, Logger, Extract or Replicat.
- **Group** shows the Extract or Replicat group or Logger process that processed the marker. `N/A` is displayed if GGSCI processed the marker.
- **Node** shows the node where the marker was inserted into the audit trails.
- There might be an additional column if user-defined text was included in the `ADD MARKER` statement.

**Syntax**

```
INFO MARKER [COUNT number]
```

**COUNT number**
Restricts the list to a specified number of the most recent markers.
Use `OBEY` to process a file that contains a list of Oracle GoldenGate commands. `OBEY` is useful for executing commands that are frequently used in sequence.

You can call one `OBEY` file from another one. This is called a nested `OBEY` file. You can nest up to 16 `OBEY` files. To use nested `OBEY` files, you must enable the functionality by first issuing the `ALLOWNESTED` command. See "ALLOWNESTED | NOALLOWNESTED" on page 1-161.

**Syntax**

```
OBEY file_name
```

*file_name*

The relative or fully qualified path name of the file that contains the list of commands.

**Examples**

**Example 1**

OBEY ./mycommands.txt

The preceding command executes a file that looks similar to the following example:

```
add extract fin, tranlog, begin now
add exttrail dirdat/aa, extract fin
add extract hr, tranlog, begin now
add exttrail dirdat/bb, extract hr
start extract *
info extract *, detail
```

**Example 2**

The following example illustrates a nested `OBEY` file. Assume an `OBEY` file named `addcmds.txt`. Inside this file, there is another `OBEY` command that calls the `OBEY` file named `startcmds.txt`, which executes another set of commands.

OBEY ./addcmds.txt

(This `OBEY` statement executes the following:)

```
add extract fin, tranlog, begin now
add exttrail ggs/dirdat/aa, extract fin
add extract hr, tranlog, begin now
add exttrail ggs/dirdat/bb, extract hr
add replicat fin2, exttrail ggs/dirdat/aa, begin now
add replicat hr2, exttrail ggs/dirdat/bb, begin now
obey ./startcmds.txt
```

(The nested `startcmds.txt` file executes the following:)

```
start extract *
info extract *, detail
start replicat *
info replicat *, detail
```
SHELL

Use SHELL to execute shell commands from within the GGSCI interface.

Syntax

\texttt{SHELL command}\n
\textit{command}

The system command to execute.

Examples

\textbf{Example 1}

\texttt{SHELL \textasciitilde dir dirprm\textasciitilde}

\textbf{Example 2}

\texttt{SHELL \textasciitilde rm \textasciitilde dat\textasciitilde}
Use **SHOW** to display the Oracle GoldenGate environment.

**Syntax**

```
SHOW
```

**Example**

The following is sample **SHOW** output. Additional entries may be displayed, depending on the database type.

Parameter settings:

- SET SUBDIRS ON
- SET DEBUG OFF

Current directory: C:\GG_81

Using subdirectories for all process files

Editor: notepad

Reports (.rpt)      C:\GG_81\dirrpt
Parameters (.prm)   C:\GG_81\dirprm
Replicat Checkpoints (.cpr) C:\GG_81\dirchk
Extract Checkpoints (.cpe) C:\GG_81\dirchk
Process Status (.pcs) C:\GG_81\dirpcs
SQL Scripts (.sql)  C:\GG_81\dirsql
Database Definitions (.def) C:\GG_81\dirdef
VERSIONS

Use VERSIONS to display operating system and database version information. For ODBC connections, the driver version is also displayed. To include database information in the output, issue a DBLOGIN command before issuing VERSIONS to establish a database connection.

Syntax

VERSIONS
Use `VIEW GGSEVT` to view the Oracle GoldenGate error log (`ggserr.log` file). This file contains information about Oracle GoldenGate events, such as process startup, shutdown, and exception conditions. This information is recorded in the system error log, too, but viewing the Oracle GoldenGate error log sometimes is more convenient and may retain events further back in time.

The display can be lengthy. To exit the display before reaching the end, use the operating system's standard methods for terminating screen output.

**Syntax**

```
VIEW GGSEVT
```

**Example**

The following is sample `VIEW GGSEVT` output:

```
2011-01-08 11:20:56  GGS INFO     301  GoldenGate Manager for Oracle, mgr.prm: Command received from GUI (START GGSCI ).
2011-01-08 11:20:56  GGS INFO     302  GoldenGate Manager for Oracle, mgr.prm: Manager started GGSCI process on port 7840.
2011-01-08 11:21:31  GGS INFO     301  GoldenGate Manager for Oracle, mgr.prm: Command received from GUI (START GGSCI ).
```
VIEW REPORT

Use `VIEW REPORT` to view the process report or the discard file that is generated by Extract or Replicat. Each process generates a new report and discard file upon startup.

Reports and discard files are aged whenever a process starts. Old files are appended with a sequence number, for example `finance0.rpt`, `finance1.rpt`, and so forth, or `discard0.dsc`, `discard1.dsc`, and so forth. To view old files, use the `[n]` option. To view the current report or discard file, use the command without the `[n]` option.

**Syntax**

```
VIEW REPORT {group_name[n] | file_name}
```

- **group_name**
  The name of the Extract or Replicat group. The command assumes the report file named `group.rpt` or the discard file named `group.dsc` in the Oracle GoldenGate `dirrpt` sub-directory.

- **n**
  The number of an old report. Report files are numbered from 0 (the most recent) to 9 (the oldest).

- **file_name**
  The relative file name if stored in the default location, or the full path name if not stored in the default location.

**Examples**

**Example 1**
The following displays an old report file (number 3) for the `orders` group.

```
VIEW REPORT orders3
```

**Example 2**
The following displays a specific discard file identified by its file name. Note that the file name has a non-default file extension.

```
VIEW REPORT dirrpt\orders.rpt
```
This chapter contains reference information for commands that can be used to control Oracle GoldenGate from the native command line of the operating system (outside the GGSCI command interface). This enables you to include the commands in scripts to run programs non-interactively.

### 2.1 Summary of Oracle GoldenGate Native Commands

This section summarizes the commands that can be issued directly from the native command line of the Linux, UNIX, Windows, or IBM i platforms. For the purposes of this document, commands issued from the IBM i PASE environment are considered UNIX commands.

On the IBM i platform, these commands are stored in the Oracle GoldenGate installation library and can be used instead of issuing them from a PASE environment. With this support, it is possible to use the typical job submission tools such as SBMJOB to operate the Oracle GoldenGate product. If submitted to batch, the output is written to a spool file, and only job messages and any exceptions are written to the job log. In a typical installation, a batch submitted command should have both a QPRINT output spool file and a joblog spool file.

To use the native commands from the IBM CLI, you need only include the Oracle GoldenGate installation library in the library list, or reference it explicitly through a qualified name such as OGGLIB/GGSCI. During the execution of the command the current directory will be set to the Oracle GoldenGate installation directory, and all appropriate environment variables will be set to operate the Oracle GoldenGate commands. Therefore, the paths for any parameter that can take a path may be specified either as an absolute path name or as a relative path name based at the Oracle GoldenGate installation directory.

The OTHERS parameter of the IBM i CLI commands is used to allow the specification of other parameters not explicitly exposed by the IBM i CLI commands. For example if you want to specify REPORTFILE and PROCESSID for Extract, you would use the following syntax:

```bash
EXTRACT PARAMFILE('dirprm/myext.prm') OTHERS(REPORTFILE 'dirrpt/myext.rpt' PROCESSID myext)
```

**Note:** Normally, Extract and Replicat should be run from GGSCI, but some situations, such as certain initial load procedures, require running them from the command line of the operating system.
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defgen</td>
<td>Runs the DEFGEN program. This program generates data definitions in a file that is transferred to a remote system to support the retrieval of object metadata.</td>
</tr>
<tr>
<td>extract</td>
<td>Runs the Extract program. This program captures either full data records or transactional data changes, depending on configuration parameters, and then sends the data to a trail for further processing by a downstream process, such as a data-pump Extract or the Replicat process.</td>
</tr>
<tr>
<td>ggsci</td>
<td>Runs the Oracle GoldenGate command line interface.</td>
</tr>
<tr>
<td>keygen</td>
<td>Runs the KEYGEN utility. This utility generates encryption keys to support Oracle GoldenGate security.</td>
</tr>
<tr>
<td>logdump</td>
<td>Runs the Logdump utility. This utility enables the contents of a trail file to be viewed for the purpose of troubleshooting. This command takes no arguments. For more information about Logdump, see Logdump Reference for Oracle GoldenGate.</td>
</tr>
<tr>
<td>mgr</td>
<td>Runs the Manager program. Manager is the parent process of Oracle GoldenGate and is responsible for the management of its processes and files, resources, user interface, and the reporting of thresholds and errors.</td>
</tr>
<tr>
<td>replicat</td>
<td>Runs the Replicat program. This program reads a trail, performs mapping and manipulation as needed, and applies the data to a target database.</td>
</tr>
</tbody>
</table>
defgen

Use `defgen` to run the DEFGEN utility from the command line of the Linux, UNIX, Windows, or IBM i operating system. The `defgen` command is installed in the Oracle GoldenGate installation directory or library.

For more information about using DEFGEN, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Syntax for Windows, UNIX, and Linux**

```
defgen paramfile parameter_file
    [noextattr]
    [pauseatend  |  nopauseatend]
    [reportfile report_file]
```

The following syntax can also be used without any other options:

```
defgen defs_file updatecs charset
```

**defgen**

Used without options, the command runs the program interactively.

**paramfile parameter_file**

Required. Specifies the relative or absolute path name of the parameter file for the DEFGEN program that is being run.

**noextattr**

Can be used to support backward compatibility with Oracle GoldenGate versions that are older than Release 11.2.1 and do not support character sets other than ASCII, nor case-sensitivity or object names that are quoted with spaces. `NOEXTATTR` prevents DEFGEN from including the database locale and character set that support the globalization features that were introduced in Oracle GoldenGate Release 11.2.1. If the table or column name has multi-byte or special characters such as white spaces, DEFGEN does not include the table definition when `NOEXTATTR` is specified. If `APPEND` mode is used in the parameter file, `NOEXTATTR` is ignored, and the new table definition is appended in the existing file format, whether with the extra attributes or not.

**pauseatend  |  nopauseatend**

(Windows only) When the process stops, requires an Oracle GoldenGate user to look at the console output and then strike any key to clear it. Also indicates whether the process ended normally or abnormally.

**reportfile report_file**

Sends command output to the specified report file. Without the `reportfile` option, the command output is printed to the screen.

**defs_file updatecs charset**

Converts the character set of a definitions file to a different character set if the file is transferred to an operating system with an incompatible character set. This procedure takes the name of the definitions file and the targeted character set as input. For example: `defgen ./dirdef/source.def UPDATECS UTF-8`.

`updatecs` helps in situations such as when a Japanese table name on Japanese Windows is written in Windows CP932 to the data-definitions file, and then the definitions file is transferred to Japanese UNIX. The file cannot be used unless the
UNIX is configured in PCK locale. Thus, you must use `updatecs` to convert the encoding of the definitions file to the correct format.

### Syntax for IBM i CLI

```bash
DEFGEN PARAMFILE(input_file)
[OTHERS(other_options)]

PARAMFILE(input_file)
The input text file, known as an OBEY file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.

OTHERS(other_options)
Any options that are supported in the UNIX version of the command provided as a space separated list.
extract

Use extract to run the Extract program from the command line of the Linux, UNIX, Windows, or IBM i operating system. The extract command is installed in the Oracle GoldenGate installation directory or library.

**Syntax for Windows, UNIX, and Linux**

```
extract paramfile parameter_file  
[atcsn  CSN | aftercsn  CSN]  
[initialdataload]  
[pauseatend | nopauseatend]  
[processid  PID]  
[reportfile  report_file]  
[usesubdirs | nousesubdirs]
```

**extract**

Used without options, the command runs the program interactively.

**paramfile parameter_file**

Required. Specifies the relative or absolute path name of the parameter file for the Extract program that is being run. The default location is the `dirprm` subdirectory of the Oracle GoldenGate installation directory.

**atcsn CSN | aftercsn CSN**

Starts the process at or after the specified commit sequence number (CSN). For more information, see "START EXTRACT" on page 1-48.

**initialdataload**

Runs Extract to extract all of the data records directly from the source database to support an initial load to the target.

**pauseatend | nopauseatend**

(Windows only) When the process stops, requires an Oracle GoldenGate user to look at the console output and then strike any key to clear it. Also indicates whether the process ended normally or abnormally.

**processid PID**

A name for the process. This name must match the name that is specified for the `EXTRACT` parameter in the parameter file. Use one alphanumeric word. When used on IBM i, this name (up to the first 10 characters) will be used as the job name in the IBM i job list.

**reportfile report_file**

Sends command output to the specified report file. Without the `reportfile` option, the command output is printed to the screen. The default is the `dirrpt` subdirectory of the Oracle GoldenGate installation directory.

**usesubdirs | nousesubdirs**

Includes the Oracle GoldenGate subdirectories when the process searches for a file to open. `usesubdirs` is the default.

**Syntax for IBM i CLI**

```
EXTRACT  PARAMFILE(input_file)  
[OTHERS{other_options}]
```
PARAMFILE(input_file)
The input text file, known as an OBEY file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.

OTHERS(other_options)
Any options that are supported in the UNIX version of the command provided as a space separated list.
Use the `ggsci` command to run the GGSCI command interface from the command line of the operating system. Optionally, you can provide input from an `OBEY` file. For more information about using an input file into GGSCI, see Administering Oracle GoldenGate for Windows and UNIX.

**Syntax for Windows, UNIX, and Linux**

```
`ggsci` [ < input_file]  
[cd directory]  
[log | nolog]
```

`<` Pipes the input file into the GGSCI program.

```
`ggsci`
```

Used without options, the command runs the program interactively.

```
`cd directory`
```

Changes the current working directory of the process. The process will use the specified directory for all of its operations, such as opening and writing files.

```
`input_file`
```

The input text file, known as an `OBEY` file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.

```
`log | nolog`
```

Enables or suppresses the logging of GGSCI commands to the report file. The default is `log`. The following commands are logged: `ADD`, `ALTER`, `CREATE`, `DELETE`, `INFO`, `START`, `STOP`, `CLEANUP`, `SEND`, `KILL`, `EDIT`, `REFRESH`.

**Syntax for IBM i CLI**

```
GGSCI [PARAMFILE (input_file)] [OTHERS(other_options)]
```

```
PARAMFILE(input_file)
```

The input text file, known as an `OBEY` file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.

```
OTHERS(other_options)
```

Any options that are supported in the UNIX version of the command provided as a space separated list.
keygen

Use keygen to generate one or more encryption keys to use with Oracle GoldenGate security features that use an ENCKEYS file. The key values are returned to your screen. You can copy and paste them into the ENCKEYS file. For more information, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

KEYGEN key_length n

keygen
Used without options, the command runs the program interactively.

key_length
The length of the encryption key, up to 256 bits (32 bytes).

n
The number of keys to generate.

Syntax for IBM i CLI

KEYGEN [KEYLEN(key_length)] [NUMKEYS(n)]

KEYGEN(key_length)
The length of the encryption key, up to 256 bits (32 bytes).

NUMKEYS(n)
The number of keys to generate.
logdump

Use logdump to run the Logdump utility. This command takes no arguments and runs interactively. For more information about the Logdump utility, see Logdump Reference for Oracle GoldenGate.

Syntax for Windows, UNIX, and Linux

logdump

Syntax for IBM i CLI

LOGDUMP
Use `mgr` to run the Manager program from the command line of the Linux, UNIX, Windows, or IBM i operating system. The `mgr` command is installed in the Oracle GoldenGate installation directory or library.

### Syntax for Windows, UNIX, and Linux

```bash
mgr paramfile parameter_file
[cd directory]
[pauseatend | nopauseatend]
[port portnum]
[reportfile report_file]
[usesubdirs | nousesubdirs]
```

`mgr`

Used without options, the command runs the program interactively.

`paramfile parameter_file`

Specifies the relative or absolute path name of the parameter file for the Manager program that is being run.

`cd directory`

Changes the current working directory of the process. The process will use the specified directory for all of its operations, such as opening and writing files.

`pauseatend | nopauseatend`

(Windows only) When the process stops, requires an Oracle GoldenGate user to look at the console output and then strike any key to clear it. Also indicates whether the process ended normally or abnormally.

`port portnum`

The number of the first port that Manager will check to start a connection. If this port number is not available, Manager increments the number by one and continues incrementing until it finds a port number that is available. However, if a port number is specified in the Manager parameter file, that number takes precedence as the start point for this search.

`reportfile report_file`

Sends command output to the specified report file. Without the `reportfile` option, the command output is printed to the screen.

`usesubdirs | nousesubdirs`

Includes the Oracle GoldenGate subdirectories when the process searches for a file to open. `usesubdirs` is the default.

### Syntax for IBM i CLI

```ibm
MGR PARAMFILE(input_file)
[OTHERS(other_options)]
```

`PARAMFILE(input_file)`

The input text file, known as an `OBEY` file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.
OTHERS(other_options)
Any options that are supported in the UNIX version of the command provided as a space separated list.
replicat

Use replicat to run the Replicat program from the command line of the Linux, UNIX, Windows, or IBM i operating system. The replicat command is installed in the Oracle GoldenGate installation directory or library.

Syntax for Window, UNIX, and Linux

```bash
replicat parameter_file
[(atcsn CSN | aftercsn CSN) [threads(thread_list)]]
[filterduptransactions]
[initialdataload]
[pauseatend | nopauseatend]
[processid PID]
[reportfile report_file]
[skiptransaction [threads(thread_list)]]
[usesubdirs | nousesubdirs]
```

replicat

Used without options, the command runs the program interactively.

parameter_file

Specifies the relative or absolute path name of the parameter file for the Replicat program that is being run. The default location is the `dirprm` subdirectory of the Oracle GoldenGate installation directory.

atcsn CSN | aftercsn CSN [threads(thread_list)]

Starts the process at or after the specified commit sequence number (CSN). For more information, see "START REPLICAT“ on page 1-78.

filterduptransactions

Causes Replicat to ignore transactions that it has already processed. For more information, see "START REPLICAT“ on page 1-78.

initialdataload

Runs Replicat to apply all of the data as an initial load to populate the target.

pauseatend | nopauseatend

(Windows only) When the process stops, requires an Oracle GoldenGate user to look at the console output and then strike any key to clear it. Also indicates whether the process ended normally or abnormally.

processid PID

A name for the process. This name must match the name that is specified for the `REPLICAT` parameter in the parameter file. Use one alphanumeric word. When used on IBM i, this name (up to the first 10 characters) will be used as the job name in the IBM i job list.

reportfile report_file

Sends command output to the specified report file. Without the `reportfile` option, the command output is printed to the screen. The default is the `dirrpt` subdirectory of the Oracle GoldenGate installation directory.

skiptransaction [threads(thread_list)]

Causes the process to skip the first transaction after its expected startup position in the trail. For more information, see “START REPLICAT“ on page 1-78.
usesubdirs | nousesubdirs
Includes the Oracle GoldenGate subdirectories when the process searches for a file to open. usesubdirs is the default.

Syntax for IBM i CLI

```
REPLICAT PARAMFILE(input_file)
[OTHERS(other_options)]

PARAMFILE(input_file)
The input text file, known as an OBEY file, containing the commands that you want to issue, in the order they are to be issued, one command per line. The name can be anything supported by the operating system.

OTHERS(other_options)
Any options that are supported in the UNIX version of the command provided as a space separated list.
This chapter contains summaries of the Oracle GoldenGate parameters that control processing, followed by detailed descriptions of each parameter in alphabetical order. For instructions on creating, changing, and storing Oracle GoldenGate parameter files, see *Administering Oracle GoldenGate for Windows and UNIX*.

### 3.1 Summary of Oracle GoldenGate Parameters

This section summarizes the Oracle GoldenGate parameters by module and purpose and includes the following topics:

- Section 3.1.1, "Summary of GLOBALS Parameters"
- Section 3.1.3, "Summary of Parameters Common to Extract and Replicat"
- Section 3.1.4, "Summary of Extract Parameters"
- Section 3.1.5, "Summary of Replicat Parameters"
- Section 3.1.6, "Summary of Wildcard Exclusion Parameters"
- Section 3.1.7, "Summary of DEFGEN Parameters"
- Section 3.1.8, "Summary of DDL Parameters"

### 3.1.1 Summary of GLOBALS Parameters

The GLOBALS file stores parameters that relate to the Oracle GoldenGate instance as a whole, as opposed to runtime parameters for a specific process.

#### Table 3–1 All GLOBALS Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRAILBYTEORDER</td>
<td>Specifies the byte order (endianness) of a file created with the EXTFILE, RMTFILE, EXTRAIL, or RMTTRAIL parameter.</td>
</tr>
<tr>
<td>CHARMAP</td>
<td>Specifies that the character mapping file overrides the character code point mapping.</td>
</tr>
<tr>
<td>CHARSET</td>
<td>Specifies a multibyte character set for the process to use instead of the operating system default when reading the parameter file.</td>
</tr>
<tr>
<td>CHECKPOINTTABLE</td>
<td>Specifies a default checkpoint table.</td>
</tr>
<tr>
<td>CREDENTIALSTORELOCATION</td>
<td>Specifies the location of the Oracle GoldenGate credential store that stores login credentials.</td>
</tr>
</tbody>
</table>
Manager is the parent process of Oracle GoldenGate and is responsible for the management of its processes, resources, user interface, and the reporting of thresholds and errors. In most cases default settings for Manager suffice.

### Table 3–2 Manager Parameters: General

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHARSET</td>
<td>Specifies a multibyte character set for the process to use instead of the operating system default when reading the parameter file.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>-- Allows insertion of comments in a parameter file.</td>
</tr>
</tbody>
</table>
Table 3–2  (Cont.) Manager Parameters: General

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOURCEDB</td>
<td>Specifies a data source name as part of the login information.</td>
</tr>
<tr>
<td>USERIDALIAS</td>
<td>Provides login information for Manager when it needs to access the database.</td>
</tr>
<tr>
<td>SYSLOG</td>
<td>Filters the types of Oracle GoldenGate messages that are written to the system logs on a Windows or UNIX system or to the SYSOPR message queue on an IBM i system.</td>
</tr>
</tbody>
</table>

Table 3–3  Manager Parameters: Port Management

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DYNAMICPORTLIST</td>
<td>Specifies the ports that Collector can dynamically allocate.</td>
</tr>
<tr>
<td>PORT</td>
<td>Establishes the TCP/IP port number on which Manager listens for requests.</td>
</tr>
</tbody>
</table>

Table 3–4  Manager Parameters: Process Management

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTORESTART</td>
<td>Specifies processes to be restarted by Manager after a failure.</td>
</tr>
<tr>
<td>AUTOSTART</td>
<td>Specifies processes to be started when Manager starts.</td>
</tr>
<tr>
<td>BOOTDELAYMINUTES</td>
<td>Determines how long after system boot time Manager delays until performing main processing activities. This parameter supports Windows.</td>
</tr>
<tr>
<td>UPREPORT</td>
<td>Determines how often process heartbeat messages are reported.</td>
</tr>
</tbody>
</table>

Table 3–5  Manager Parameters: Event Management

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOWNCRITICAL</td>
<td>Reports processes that stopped gracefully or abnormally.</td>
</tr>
<tr>
<td>DOWNREPORT</td>
<td>Controls the frequency for reporting stopped processes.</td>
</tr>
<tr>
<td>LAGCRITICAL</td>
<td>Specifies a lag threshold that is considered critical and generates a warning to the error log.</td>
</tr>
<tr>
<td>LAGINFO</td>
<td>Specifies a lag threshold at which an informational message is reported to the error log.</td>
</tr>
<tr>
<td>LAGREPORT</td>
<td>Sets an interval for reporting lag time to the error log.</td>
</tr>
</tbody>
</table>

Table 3–6  Manager Parameters: Maintenance

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHECKMINUTES</td>
<td>Determines how often Manager cycles through maintenance activities.</td>
</tr>
<tr>
<td>PURGEDDLHISTORY</td>
<td>PURGEDDLHISTORYALT</td>
</tr>
<tr>
<td>PURGEMARKERHISTORY</td>
<td>Purges Oracle marker table rows that are no longer needed.</td>
</tr>
<tr>
<td>PURGEOLEDEXTRACTS for Extract and Replicat</td>
<td>Purges trail data that is no longer needed.</td>
</tr>
</tbody>
</table>
### 3.1.3 Summary of Parameters Common to Extract and Replicat

These parameters are available for both the Extract and Replicat processes.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PURGEOLDTASKS</td>
<td>Purges Extract and Replicat tasks after a specified period of time.</td>
</tr>
<tr>
<td>STARTUPVALIDATIONDELAY[CSECS]</td>
<td>Sets a delay time after which Manager checks that processes are still running after startup.</td>
</tr>
</tbody>
</table>

#### Table 3–7 Parameters Common to Extract and Replicat: General

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCFILES</td>
<td>Controls the incremental number of memory structures that are allocated after the initial memory allocation specified by the NUMFILES parameter is reached.</td>
</tr>
<tr>
<td>CHARSET</td>
<td>Specifies a multibyte character set for the process to use instead of the operating system default when reading the parameter file.</td>
</tr>
<tr>
<td>CHECKPARAMS</td>
<td>Verifies parameter file syntax.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>Denotes comments in a parameter file.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Retrieves variables that were set with the SETENV parameter.</td>
</tr>
<tr>
<td>OBEY</td>
<td>Processes parameter statements contained in a different parameter file.</td>
</tr>
<tr>
<td>SETENV</td>
<td>Specifies a value for a UNIX environment variable from within the GGSCI interface.</td>
</tr>
<tr>
<td>TRACETABLE</td>
<td>Specifies a trace table to which Replicat adds a record whenever it updates the target database. Causes Extract to ignore database changes generated by Replicat. Supports Oracle bi-directional replication.</td>
</tr>
<tr>
<td>USERID</td>
<td>Specifies database connection information.</td>
</tr>
<tr>
<td>USERIDALIAS</td>
<td>Specifies database connection information when a credential store is in use.</td>
</tr>
</tbody>
</table>

#### Table 3–8 Parameters Common to Extract and Replicat: Selection, Converting, and Mapping Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOWDUPTARGETMAP</td>
<td>Allows the same source-target MAP statement to appear more than once in the parameter file.</td>
</tr>
<tr>
<td>NOALLOWDUPTARGETMAP</td>
<td></td>
</tr>
<tr>
<td>ASCII TO EBCDIC</td>
<td>Converts ASCII text to EBCDIC for DB2 on z/OS systems running UNIX System Services.</td>
</tr>
<tr>
<td>CATALOGEXCLUDE</td>
<td>Excludes the specified source container or catalog from a wildcard specification.</td>
</tr>
<tr>
<td>COLMATCH</td>
<td>Establishes global column-mapping rules.</td>
</tr>
<tr>
<td>DDL</td>
<td>Enables and filters the capture of DDL operations.</td>
</tr>
</tbody>
</table>
### Table 3–8  Parameters Common to Extract and Replicat: Selection, Converting, and Mapping Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDLSUBST</td>
<td>Enables string substitution in DDL processing.</td>
</tr>
<tr>
<td>GETDELETES</td>
<td>IGNOREDELETES</td>
</tr>
<tr>
<td>GETINSERTS</td>
<td>IGNOREINSERTS</td>
</tr>
<tr>
<td>GETTRUNCATES</td>
<td>IGNORETRUNCATES</td>
</tr>
<tr>
<td>GETUPDATEAFTERS</td>
<td>IGNOREUPDATEAFTERS</td>
</tr>
<tr>
<td>GETUPDATEBEFORESE</td>
<td>IGNOREUPDATEBEFORESE</td>
</tr>
<tr>
<td>GETUPDATES</td>
<td>IGNOREUPDATES</td>
</tr>
<tr>
<td>NAMECCSID</td>
<td>Specifies a DB2 for i CCSID if the object names in the SQL catalog are of a different CCSID than the system.</td>
</tr>
<tr>
<td>REPLACEBADCHAR</td>
<td>Replaces invalid character values with another value.</td>
</tr>
<tr>
<td>SCHEMAEXCLUDE</td>
<td>Excludes the specified source schema from a wildcard specification.</td>
</tr>
<tr>
<td>SOURCEDEFS</td>
<td>Specifies a file that contains source data definitions created by the <code>DEFGEN</code> utility.</td>
</tr>
<tr>
<td>SOURCECATALOG</td>
<td>Specifies a default container or catalog for all following <code>TABLE</code> or <code>MAP</code> statements.</td>
</tr>
<tr>
<td>TRIMSPACES</td>
<td>NOTRIMSPACES</td>
</tr>
<tr>
<td>VARWIDTHNCHAR</td>
<td>NOVARWIDTHNCHAR</td>
</tr>
<tr>
<td>WILDCARDRESOLVE</td>
<td>Defines rules for processing wildcard table specifications in a <code>TABLE</code> statement.</td>
</tr>
</tbody>
</table>

### Table 3–9  Parameters Common to Extract and Replicat: Custom Processing

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSEREXIT</td>
<td>Invokes a user exit routine during processing.</td>
</tr>
<tr>
<td>INCLUDE</td>
<td>Invokes a macro library.</td>
</tr>
<tr>
<td>MACRO</td>
<td>Defines an Oracle GoldenGate macro.</td>
</tr>
<tr>
<td>MACROCHAR</td>
<td>Defines a macro character other than the default of <code>#</code>.</td>
</tr>
<tr>
<td>SQLEXEC</td>
<td>Executes a stored procedure or query during Extract processing.</td>
</tr>
</tbody>
</table>

### Table 3–10  Parameters Common to Extract and Replicat: Reporting

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMDTRACE</td>
<td>Displays macro expansion steps in the report file.</td>
</tr>
</tbody>
</table>
### Table 3–10 (Cont.) Parameters Common to Extract and Replicat: Reporting

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIST</td>
<td>NOLIST</td>
</tr>
<tr>
<td>REPORT</td>
<td></td>
</tr>
<tr>
<td>STATOPTIONS</td>
<td></td>
</tr>
<tr>
<td>REPORTCOUNT</td>
<td></td>
</tr>
<tr>
<td>TRACE</td>
<td>TRACE2</td>
</tr>
</tbody>
</table>

### Table 3–11 Parameters common to Extract and Replicat: Tuning

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCFILES</td>
<td></td>
</tr>
<tr>
<td>CACHEMGR</td>
<td></td>
</tr>
<tr>
<td>CHECKPOINTSECS</td>
<td></td>
</tr>
<tr>
<td>DBOPTIONS</td>
<td></td>
</tr>
<tr>
<td>DDLOPTIONS</td>
<td></td>
</tr>
<tr>
<td>DYNAMICRESOLUTION</td>
<td>NODYNAMICRESOLUTION</td>
</tr>
<tr>
<td>EOFDELAY</td>
<td>EOFDELAYCSECS</td>
</tr>
<tr>
<td>FUNCTIONSTACKSIZE</td>
<td></td>
</tr>
<tr>
<td>NUMFILES</td>
<td></td>
</tr>
</tbody>
</table>

### Table 3–12 Parameters Common to Extract and Replicat: Error Handling

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDLERROR</td>
<td></td>
</tr>
<tr>
<td>DISCARDFILE</td>
<td></td>
</tr>
<tr>
<td>NODISCARDFILE</td>
<td></td>
</tr>
</tbody>
</table>

### Table 3–13 Parameters Common to Extract and Replicat: Maintenance

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISCARDROLLOVER</td>
<td></td>
</tr>
</tbody>
</table>
3.1.4 Summary of Extract Parameters

The Extract process captures either full data records or transactional data changes, depending on configuration parameters, and then sends the data to a target system to be applied to target tables or processed further by another process, such as a load utility.

Table 3–14  Extract Parameters: General

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECOVERYOPTIONS</td>
<td>Controls the recovery mode of the Extract process.</td>
</tr>
<tr>
<td>SOURCEDB</td>
<td>Specifies the data source as part of the login information.</td>
</tr>
<tr>
<td>TCPSOURCETIMER</td>
<td>Adjusts timestamps of records transferred to other systems when those systems reflect different times.</td>
</tr>
<tr>
<td>UPDATERECORDFORMAT</td>
<td>Controls whether before and after images are stored in one trail record or two.</td>
</tr>
</tbody>
</table>

Table 3–15  Extract Parameters: Processing Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSOPTIONS</td>
<td>Specifies Extract processing options when a Teradata Access Module (TAM) is being used.</td>
</tr>
<tr>
<td>EXTRACT</td>
<td>Defines an Extract group as an online process.</td>
</tr>
<tr>
<td>GETAPPLOPS</td>
<td>IGNOREAPPLOPS</td>
</tr>
<tr>
<td>GETREPLICATES</td>
<td>IGNOREREPLICATES</td>
</tr>
<tr>
<td>PASSTHRU</td>
<td>NOPASSTHRU</td>
</tr>
<tr>
<td>PASSTHRUMESSAGES</td>
<td>NOPASSTHRUMESSAGES</td>
</tr>
<tr>
<td>RMTTASK</td>
<td>Creates a processing task on a remote system.</td>
</tr>
<tr>
<td>SOURCEISTABLE</td>
<td>Extracts entire records from source tables.</td>
</tr>
<tr>
<td>VAM</td>
<td>Indicates that a Teradata Access Module (TAM) is being used to provide transactional data to the Extract process.</td>
</tr>
</tbody>
</table>
### Extract Parameters: Selecting, Converting, and Mapping Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPRESSDELETES</td>
<td>Controls whether Oracle GoldenGate writes only the key or all columns to the trail for delete operations.</td>
</tr>
<tr>
<td>COMPRESSUPDATES</td>
<td>Causes only primary key columns and changed columns to be logged for updates.</td>
</tr>
<tr>
<td>EXCLUDETAG</td>
<td>Specifies Replicat or data pump changes to be excluded from trail files.</td>
</tr>
<tr>
<td>FETCHOPTIONS</td>
<td>Controls certain aspects of the way that Oracle GoldenGate fetches data.</td>
</tr>
<tr>
<td>LOGALLSUPCOLS</td>
<td>Logs the columns that are required to support Conflict Detection and Resolution and Integrated Replicat.</td>
</tr>
<tr>
<td>SEQUENCE</td>
<td>Specifies sequences for synchronization.</td>
</tr>
<tr>
<td>TABLE</td>
<td>Specifies tables for extraction and controls column mapping and conversion.</td>
</tr>
<tr>
<td>TABLEEXCLUDE</td>
<td>Excludes source tables from the extraction process.</td>
</tr>
<tr>
<td>TARGETDEFS</td>
<td>Specifies a file containing target table definitions for target databases that reside on the NonStop platform.</td>
</tr>
<tr>
<td>TRAILCHARSETASCII</td>
<td>Specifies the ASCII character set for data captured from DB2 on z/OS, when both ASCII and EBCDIC tables are present.</td>
</tr>
<tr>
<td>TRAILCHARSETEBCDIC</td>
<td>Specifies the EBCDIC character set for data captured from DB2 on z/OS, when both ASCII and EBCDIC tables are present.</td>
</tr>
</tbody>
</table>

### Extract Parameters: Routing Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTFILE</td>
<td>Specifies an extract file to which extracted data is written on the local system.</td>
</tr>
<tr>
<td>EXTTRAIL</td>
<td>Specifies a trail to which extracted data is written on the local system.</td>
</tr>
<tr>
<td>RMFILE</td>
<td>Specifies an extract file to which extracted data is written on a remote system.</td>
</tr>
<tr>
<td>RMHOST</td>
<td>Specifies the target system and Manager port number.</td>
</tr>
<tr>
<td>RMTTRAIL</td>
<td>Specifies a trail to which extracted data is written on a remote system.</td>
</tr>
</tbody>
</table>

### Extract Parameters: Formatting Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORMATASCII</td>
<td>Formats extracted data in external ASCII format.</td>
</tr>
<tr>
<td>FORMATSQL</td>
<td>Formats extracted data into equivalent SQL statements.</td>
</tr>
<tr>
<td>FORMATXML</td>
<td>Formats extracted data into equivalent XML syntax.</td>
</tr>
<tr>
<td>NOHEADERS</td>
<td>Prevents record headers from being written to the trail.</td>
</tr>
</tbody>
</table>
**Table 3–19   Extract Parameters: Tuning**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BR</td>
<td>Controls the Bounded Recovery feature of Extract.</td>
</tr>
<tr>
<td>CACHEMGR</td>
<td>Controls the virtual memory cache manager.</td>
</tr>
<tr>
<td>FLUSHSECS</td>
<td>FLUSHSECS</td>
</tr>
<tr>
<td>LOBMEMORY</td>
<td>Controls the amount of memory and temporary disk space available for caching transactions that contain LOBs.</td>
</tr>
<tr>
<td>RMTHOSTOPTIONS</td>
<td>Specifies connection attributes other than host information for a TCP/IP connection used by a passive Extract group.</td>
</tr>
<tr>
<td>THREADOPTIONS</td>
<td>Controls aspects of the way that Extract operates in an Oracle Real Application Cluster environment.</td>
</tr>
<tr>
<td>TRANLOGOPTIONS</td>
<td>Supplies capture processing options.</td>
</tr>
<tr>
<td>TRANSMEMORY</td>
<td>Controls the amount of memory and temporary disk space available for caching uncommitted transaction data.</td>
</tr>
<tr>
<td>WARNLONGTRANS</td>
<td>Defines a long-running transaction and controls the frequency of checking for and reporting them.</td>
</tr>
</tbody>
</table>

**Table 3–20   Extract Parameters: Maintenance**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROLLOVER</td>
<td>Specifies the way that trail files are aged.</td>
</tr>
</tbody>
</table>

**Table 3–21   Extract Parameters: Security**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECRYPTTRAIL</td>
<td>Required to decrypt data when Extract is used as a data pump and must do work on the data.</td>
</tr>
<tr>
<td>ENCRYPTTRAIL</td>
<td>NOENCRYPTTRAIL</td>
</tr>
</tbody>
</table>

**3.1.5 Summary of Replicat Parameters**

The Replicat process reads data extracted by the Extract process and applies it to target tables or prepares it for use by another application, such as a load utility.

**Table 3–22   Replicat Parameters: General**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TARGETDB</td>
<td>Specifies the data source as part of the login information.</td>
</tr>
<tr>
<td>HAVEUDTWITHNCHAR</td>
<td>Causes Replicat to connect in UTF-8 to prevent data loss when the record being processed is a user-defined type that has an NCHAR/NVARCHAR2 attribute.</td>
</tr>
</tbody>
</table>

**Table 3–23   Replicat Parameters: Processing Method**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEGIN</td>
<td>Specifies a starting point for Replicat processing. Required when SPECIALRUN is specified.</td>
</tr>
</tbody>
</table>
Table 3–23  (Cont.) Replicat Parameters: Processing Method

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BULKLOAD</td>
<td>Loads data directly into the interface of the Oracle SQL*Loader utility.</td>
</tr>
<tr>
<td>END</td>
<td>Specifies a stopping point for Replicat processing. Required when using</td>
</tr>
<tr>
<td></td>
<td>SPECIALRUN.</td>
</tr>
<tr>
<td>GENLOADFILES</td>
<td>Generates run and control files that are compatible with a database load</td>
</tr>
<tr>
<td></td>
<td>utility.</td>
</tr>
<tr>
<td>REPLICAT</td>
<td>Specifies a Replicat group for online change synchronization.</td>
</tr>
<tr>
<td>SPECIALRUN</td>
<td>Used for one-time processing that does not require checkpointing from run</td>
</tr>
<tr>
<td></td>
<td>to run.</td>
</tr>
</tbody>
</table>

Table 3–24  Replicat Parameters: Selecting, Converting, and Mapping Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOWNOOPUPDATES</td>
<td>NOALLOWNOOPUPDATES</td>
</tr>
<tr>
<td>APPLYNOOPUPDATES</td>
<td>NOAPPLYNOOPUPDATES</td>
</tr>
<tr>
<td>ASSUMETARGETDEFS</td>
<td>Assumes that source and target tables have the same column structure.</td>
</tr>
<tr>
<td>INSERTALLRECORDS</td>
<td>Inserts a new record into the target table for every change operation made to a record.</td>
</tr>
<tr>
<td>INSERTDELETES</td>
<td>NOINSERTDELETES</td>
</tr>
<tr>
<td>INSERTMISSINGUPDATES</td>
<td>NOINSERTMISSINGUPDATES</td>
</tr>
<tr>
<td>INSERTUPDATES</td>
<td>NOINSERTUPDATES</td>
</tr>
<tr>
<td>TABLE</td>
<td>MAP</td>
</tr>
<tr>
<td>MAPEXCLUDE</td>
<td>Excludes source tables from being processed by a wildcard specification supplied in MAP statements.</td>
</tr>
<tr>
<td>PRESERVETARGETTIMEZONE</td>
<td>Overrides the default Replicat session time zone.</td>
</tr>
<tr>
<td>REPLACEBADNUM</td>
<td>Specifies a global substitution value for invalid numeric data encountered when mapping number columns.</td>
</tr>
<tr>
<td>SOURCECHARSET</td>
<td>Controls whether the source character set it converted to the target character set.</td>
</tr>
<tr>
<td>SOURCETIMEZONE</td>
<td>Specifies the time zone of the source database for Replicat to use as the session time zone.</td>
</tr>
<tr>
<td>SPACESTONULL</td>
<td>NOSPACESTONULL</td>
</tr>
<tr>
<td>TABLE for Replicat</td>
<td>Specifies a table or tables for which event actions are to take place when a row satisfies the given filter criteria.</td>
</tr>
<tr>
<td>UPDATEINSERTS</td>
<td>NOUPDATEINSERTS</td>
</tr>
</tbody>
</table>
### Table 3–24  Replicat Parameters: Selecting, Converting, and Mapping Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UPDATEDDELETES</td>
<td>Converts deletes to updates.</td>
</tr>
<tr>
<td>UPDATEDDELETES</td>
<td>Converts inserts to updates.</td>
</tr>
<tr>
<td>USEDEDICATEDCOORDINATIONTHREAD</td>
<td>Specifies a dedicated thread for barrier transactions when Replicat is in coordinated mode.</td>
</tr>
</tbody>
</table>

### Table 3–25  Replicat Parameters: Routing Data

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTFILE</td>
<td>Defines the name of an extract file on the local system that contains data to be replicated. Used for one-time processing.</td>
</tr>
<tr>
<td>EXTRAIL</td>
<td>Defines a trail containing data to be replicated. Used for one-time processing.</td>
</tr>
</tbody>
</table>

### Table 3–26  Replicat Parameters: Error Handling and Reporting

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HANDLECOLLISIONS</td>
<td>Handles errors for duplicate and missing records.</td>
</tr>
<tr>
<td>HANDLETPKUPDATE</td>
<td>Prevents constraint errors associated with replicating transient primary key updates.</td>
</tr>
<tr>
<td>OVERRIDEDUPS</td>
<td>Overlays a replicated insert record onto an existing target record whenever a duplicate-record error occurs.</td>
</tr>
<tr>
<td>RESTARTCOLLISIONS</td>
<td>Controls whether or not Replicat applies HANDLECOLLISIONS logic after Oracle GoldenGate has abended because of a conflict.</td>
</tr>
<tr>
<td>REPERROR</td>
<td>Determines how Replicat responds to database errors.</td>
</tr>
<tr>
<td>REPFETCHEDCOLOPTIONS</td>
<td>Determines how Replicat responds to operations for which a fetch from the source database was required.</td>
</tr>
<tr>
<td>SHOWSYNTAX</td>
<td>Causes Replicat to print its SQL statements to the report file.</td>
</tr>
<tr>
<td>SQLDUPERR</td>
<td>Specifies the database error number that indicates a duplicate record. Use with OVERRIDEDUPS.</td>
</tr>
<tr>
<td>WARNRATE</td>
<td>Determines how often database errors are reported.</td>
</tr>
</tbody>
</table>

### Table 3–27  Replicat Parameters: Tuning

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BATCHSQL</td>
<td>Increases the throughput of Replicat processing by arranging similar SQL statements into arrays and applying them at an accelerated rate.</td>
</tr>
<tr>
<td>COORDSTATINTERVAL</td>
<td>The interval at which the coordinator thread sends a request to the apply threads for statistics.</td>
</tr>
</tbody>
</table>
### 3.1.6 Summary of Wildcard Exclusion Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXCLUDEWILDCARDOBJECTSONLY</td>
<td>Forces the inclusion of non-wildcarded source objects specified in TABLE or MAP parameters when an exclusion parameter contains a wildcard that otherwise would exclude that object.</td>
</tr>
<tr>
<td>MAPEXCLUDE</td>
<td>Excludes a source object from a MAP statement.</td>
</tr>
<tr>
<td>TABLEEXCLUDE</td>
<td>Excludes a source object from a TABLE statement.</td>
</tr>
<tr>
<td>CATALOGEXCLUDE</td>
<td>Excludes source objects in the specified source container or catalog from the Oracle GoldenGate configuration when the container or catalog name is being specified with a wildcard in TABLE or MAP statements.</td>
</tr>
<tr>
<td>SCHEMAEXCLUDE</td>
<td>Excludes source objects that are owned by the specified source owner (such as a schema) from the Oracle GoldenGate configuration when wildcards are being used to specify the owners in TABLE or MAP statements.</td>
</tr>
</tbody>
</table>

### 3.1.7 Summary of DEFGEN Parameters

DEFGEN creates a file with data definitions for source or target tables. Data definitions are needed when the source and target tables have different definitions or the databases are of different types.
### 3.1.8 Summary of DDL Parameters

These parameters control Oracle GoldenGate DDL support. Other parameters may be required with DDL support, but the ones here deal specifically with the DDL feature.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDL</td>
<td>Enables DDL support and filters DDL.</td>
</tr>
<tr>
<td>DDLERROR</td>
<td>Handles errors that occur during DDL replication.</td>
</tr>
<tr>
<td>DDLOPTIONS</td>
<td>Configures aspects of DDL replication other than filtering and string substitution.</td>
</tr>
<tr>
<td>DDLSUBST</td>
<td>Enables the substitution of strings in DDL operations.</td>
</tr>
<tr>
<td>DDLTABLE</td>
<td>Specifies an alternate name for the DDL history table.</td>
</tr>
<tr>
<td>GGSCHEMA</td>
<td>Specifies the name of the schema that contains the objects that support DDL replication.</td>
</tr>
<tr>
<td>PURGEDDLHISTORY</td>
<td>Controls the size of the DDL history table.</td>
</tr>
<tr>
<td>PURGEDDLHISTORYALT</td>
<td></td>
</tr>
<tr>
<td>PURGEMARKERHISTORY</td>
<td>Controls the size of the DDL marker table.</td>
</tr>
</tbody>
</table>
ALLOCFILES

Valid For

Extract and Replicat

Description

Use the ALLOCFILES parameter to control the incremental number of memory structures that are allocated after the initial memory allocation specified by the NUMFILES parameter is reached. Together, these parameters control how process memory is allocated for storing information about the source and target tables being processed.

The default values should be sufficient for both NUMFILES and ALLOCFILES, because memory is allocated by the process as needed, system resources permitting.

ALLOCFILES must occur before any TABLE or MAP entries to have any effect.

See "NUMFILES" on page 3-205 for more information.

Default

500

Syntax

ALLOCFILES number

number

The additional number of memory structures to be allocated. Do not set ALLOCFILES to an arbitrarily high number, or memory will be consumed unnecessarily. The memory structures of Oracle GoldenGate support up to two million tables.

Example

ALLOCFILES 1000
ALLOWDUPTARGETMAP | NOALLOWDUPTARGETMAP

Valid For

Extract and Replicat

Description

Use the ALLOWDUPTARGETMAP and NOALLOWDUPTARGETMAP parameters to control whether or not the following are accepted in a parameter file:

- In an Extract parameter file: duplicate TABLE parameters for the same source object if the COLMAP option is used in any of them. By default, Extract abends on duplicate TABLE statements when COLMAP is used.
- In a Replicat parameter file: duplicate MAP statements for the same source and target objects. By default, duplicate MAP statements cause Replicat to abend.

If ALLOWDUPTARGETMAP is not specified and the same source and target tables are mapped more than once, only the first MAP statement is used and the others are ignored.

Default

NOALLOWDUPTARGETMAP

Syntax

ALLOWDUPTARGETMAP | NOALLOWDUPTARGETMAP

Examples

Example 1

The following Extract parameter file is permissible with ALLOWDUPTARGETMAP enabled.

EXTRACT extcust
USERIDALIAS tiger1
EXTTRAIL dirdat/aa
TABLE ogg.tcustmer;
EXTTRAIL dirdat/bb
TABLE ogg.tcustmer, TARGET ogg.tcustmer, COLMAP (USEDEFAULTS, col1=id, col2=name);

Example 2

The following Replicat parameter file is permissible with ALLOWDUPTARGETMAP enabled.

REPLICAT repcust
USERIDALIAS tiger1
SOURCEDEFS /ggs/dirdef/source.def
ALLOWDUPTARGETMAP
GETINSERTS
GETUPDATES
IGNOREDELETES

ALLOWINVISIBLEINDEXKEYS

Valid For

GLOBAL

Description

Use the ALLOWINVISIBLEINDEXKEYS parameter in the GLOBALS file to allow Extract and Replicat to use columns that are part of an Oracle invisible index as a unique row identifier. By default, the process abends when this type of index is the only available unique identifier.

Note: To enable trigger-based DDL replication to use Oracle invisible indexes, set the following parameter to 'TRUE' in the params.sql script:

define allow_invisible_index_keys = 'TRUE'

This functionality is automatically enabled for integrated capture and Replicat.

Default

None

Syntax

ALLOWINVISIBLEINDEXKEYS
ALLOWNONVALIDATEDKEYS

Valid For

GLOBALS

Description

Use ALLOWNONVALIDATEDKEYS to allow Extract, Replicat, and GGSCI commands to use a non-validated primary key or an invalid key as a unique identifier. This parameter overrides the key selection criteria that is used by Oracle GoldenGate. When it is enabled, Oracle GoldenGate will use NON VALIDATED and NOT VALID primary keys as a unique identifier.

A key can become invalid as the result of an object reorganization or a number of other actions, but if you know the keys are valid, ALLOWNONVALIDATEDKEYS saves the downtime of re-validating them, especially in a testing environment. However, when using ALLOWNONVALIDATEDKEYS, whether in testing or in production, you accept the risk that the target data may not be maintained accurately through replication. If a key proves to be non-valid and the table on which it is defined contains more than one record with the same key value, Oracle GoldenGate might choose the wrong target row to update.

To enable ALLOWNONVALIDATEDKEYS in a configuration where DDL replication is not active, stop all processes, add ALLOWNONVALIDATEDKEYS to the GLOBALS parameter file, and then restart the processes. To disable ALLOWNONVALIDATEDKEYS again, remove it from the GLOBALS file and then restart the processes.

To enable ALLOWNONVALIDATEDKEYS functionality in a configuration where DDL support is active, take the following steps.

1. Add the ALLOWNONVALIDATEDKEYS parameter to the GLOBALS parameter file.
2. Update the GGS_SETUP table in the DDL schema by using the following SQL.
   ```sql
   UPDATE owner.GGS_SETUP SET value='1' WHERE property='ALLOWNONVALIDATEDKEYS';
   COMMIT;
   ```
3. Restart all Oracle GoldenGate processes including Manager. From this point on, Oracle GoldenGate selects non-validated or non-valid primary keys as a unique identifier.

To disable ALLOWNONVALIDATEDKEYS functionality when DDL support is active, take the following steps.

1. Remove ALLOWNONVALIDATEDKEYS from the GLOBALS parameter file.
2. Update the record that you added to the GGS_SETUP table to 0.
3. Restart all of the Oracle GoldenGate processes.

Default

None (Disabled)

Syntax

ALLOWNONVALIDATEDKEYS
ALLOWNOOPUPDATES | NOALLOWNOOPUPDATES

Valid For

Replicat

Description

Use ALLOWNOOPUPDATES and NOALLOWNOOPUPDATES to control how Replicat responds to a no-op operation. A no-op operation is one in which there is no effect on the target table. The following are some examples of how this can occur.

- The source table has a column that does not exist in the target table, or it has a column that was excluded from replication (with a COLSEXCEPT clause). In either case, if that source column is updated, there will be no target column name to use in the SET clause within the Replicat SQL statement.

- An update is made that sets a column to the same value as the current one. The database does not log the new value, because it did not change. However, Oracle GoldenGate captures the operation as a change record because the primary key was logged, but there is no column value for the SET clause in the Replicat SQL statement.

By default (NOALLOWNOOPUPDATES), Replicat abends with an error because these types of operations do not update the database. With ALLOWNOOPUPDATES, Replicat ignores the operation instead of abending. The statistics reported by Replicat will show that an UPDATE was made, but the database does not get updated.

You can use the internal parameter APPLYNOOPUPDATES to force the UPDATE to be applied. APPLYNOOPUPDATES overrides ALLOWNOOPUPDATES. If both are specified, Replicat applies updates for which there are key columns for the source and target tables. By default, Oracle GoldenGate abends with the following message when there is a key on the source table but no key on the target table.

2011-01-25 02:28:42 GGS ERROR    160 Encountered an update for target table TELLER, which has no unique key defined. KEYCOLS can be used to define a key. Use ALLOWNOOPUPDATES to process the update without applying it to the target database. Use APPLYNOOPUPDATES to force the update to be applied using all columns in both the SET and WHERE clause.

If ALLOWNOOPUPDATES is specified when the HANDLECOLLISIONS or INSERTMISSINGUPDATES parameter is being used, and if Oracle GoldenGate has all of the target key values, Oracle GoldenGate applies an UPDATE by using all of the columns of the table in the SET clause and the WHERE clause (invoking APPLYNOOPUPDATES behavior). This is necessary so that Oracle GoldenGate can determine whether the row is present or missing. If it is missing, Oracle GoldenGate converts the UPDATE to an INSERT.

Default

NOALLOWNOOPUPDATES (only applies if the table does not have a key)

Syntax

ALLOWNOOPUPDATES | NOALLOWNOOPUPDATES
APPLYNOOPUPDATES | NOAPPLYNOOPUPDATES

Valid For

Replicat

Description

Use APPLYNOOPUPDATES to force a no-op UPDATE operation to be applied by using all of the columns in the SET and WHERE clauses. See ALLOWNOOPUPDATES | NOALLOWNOOPUPDATES for a description of no-op.

APPLYNOOPUPDATES causes Replicat to use whatever data is in the trail. If there is a primary-key UPDATE record, Replicat uses the before columns from the source. If there is a regular (non-key) UPDATE, Replicat assumes that the after value is the same as the before value (otherwise it would be a primary-key update). The preceding assumes source and target keys are identical. If they are not, you must use a KEYCOLS clause in the TABLE statement on the source.

Default

NOAPPLYNOOPUPDATES

Syntax

APPLYNOOPUPDATES | NOAPPLYNOOPUPDATES
ASCIITOEBCDIC

Valid For

Extract data pump and Replicat

Description

Use the ASCIITOEBCDIC parameter to control the conversion of data in the input trail file from ASCII to EBCDIC format. This parameter should only be used to support backward compatibility in cases where the input trail file was created by an Extract version prior to v10.0. It is ignored for all other cases, because ASCII to EBCDIC conversion is currently the default.

As of version 11.2.1, conversion is not allowed by a data pump.

Default

None

Syntax

ASCIITOEBCDIC
ASSUMETARGETDEFS

Valid For

Replicat

Description

Use the ASSUMETARGETDEFS parameter when the source and target objects specified in a MAP statement have identical column structure, such as when synchronizing a hot site. It directs Oracle GoldenGate to assume that the data definitions of the source and target objects are identical, and to refer to the target definitions when metadata is needed for the source data.

When source and target tables have dissimilar structures, do not use ASSUMETARGETDEFS. Create a data-definitions file for the source object, and specify the definitions file with the SOURCEDEFS parameter. See "SOURCEDEFS" on page 3-282 for more information. Do not use ASSUMETARGETDEFS and SOURCEDEFS in the same parameter file.

See Administering Oracle GoldenGate for Windows and UNIX for more information about metadata and how it applies to Oracle GoldenGate.

Default

None

Syntax

ASSUMETARGETDEFS
AUTORESTART

Valid For

Manager

Description

Use the AUTORESTART parameter to start one or more Extract and Replicat processes automatically after they fail. AUTORESTART provides fault tolerance when something temporary interferes with a process, such as intermittent network outages or programs that interrupt access to transaction logs.

You can use multiple AUTORESTART statements in the same parameter file.

To apply this parameter to an Extract group that is created in PASSIVE mode, use it for the Manager that is on the target system where the associated alias Extract group resides. Oracle GoldenGate will send the start command to the source system. If AUTORESTART is used locally for a passive Extract group, it is ignored.

If Manager encounters an out-of-order transaction upon restart, it will not restart Extract. Instead, it will log a warning that notifies you to use the ETROLLOVER option of SEND EXTRACT to advance the trail to skip the transaction that caused the error.

Default

Do not auto-restart

Syntax

AUTORESTART {EXTRACT | REPLICAT | ER} group_name
   [, RETRIES number]
   [, WAITMINUTES {minutes | seconds}]
   [, RESETMINUTES {minutes | seconds}]

EXTRACT
Restarts Extract automatically.

REPLICAT
Restarts Replicat automatically.

ER
Restarts Extract and Replicat automatically.

group_name
A group name or wildcard specification for multiple groups. When wildcarding is used, Oracle GoldenGate starts all groups of the specified process type on the local system that satisfy the wildcard, except those in PASSIVE mode.

RETRIES number
The maximum number of times that Manager should try to restart a process before aborting retry efforts. The default number of tries is 2.

WAITMINUTES {minutes | seconds}
The amount of time, in minutes or seconds, to pause between discovering that a process has terminated abnormally and restarting the process. Use this option to delay restarting until a necessary resource becomes available or some other event occurs. The default delay is 2 minutes or 120 seconds.
**RESETMINUTES** *(minutes | seconds)*

The window of time, in minutes or seconds, during which retries are counted. The default is 120 minutes (2 hours) or 7200 seconds. After the time expires, the number of retries reverts to zero.

**Example**

In the following example, Manager tries to start all Extract processes three times after failure within a one hour time period, and it waits five minutes before each attempt.

```
AUTORESTART EXTRACT *, RETRIES 3, WAITMINUTES 5, RESETMINUTES 60
```
**AUTOSTART**

**Valid For**

Manager

**Description**

Use the `AUTOSTART` parameter to start one or more Extract and Replicat processes automatically when Manager starts. `AUTOSTART` ensures that no process groups are overlooked and that synchronization activities start immediately.

You can use multiple `AUTOSTART` statements in the same parameter file.

To apply this parameter to an Extract group that is created in `PASSIVE` mode, use it for the Manager that is on the target system where the associated alias Extract group resides. Oracle GoldenGate will send the start command to the source system. If `AUTOSTART` is used locally for a passive Extract group, it is ignored.

If Manager encounters an out-of-order transaction upon restart, it will not restart Extract. Instead, it will log a warning that notifies you to use the `ETROLLOVER` option of `SEND EXTRACT` to advance the trail to skip the transaction that caused the error.

**Default**

Do not autostart

**Syntax**

`AUTOSTART {{EXTRACT | REPLICAT | ER} group_name | JAGENT}

**EXTRACT**

Starts Extract automatically.

**REPLICAT**

Starts Replicat automatically.

**ER**

Starts Extract and Replicat automatically.

**JAGENT**

Starts the Oracle GoldenGate Monitor JAgent automatically. For more information, see *Administering Oracle GoldenGate Monitor*.

`group_name`

Valid for `EXTRACT`, `REPLICAT`, `ER` only. `JAGENT` does not take a group name as input. Specifies a group name or wildcard specification for multiple groups. When wildcards are used, Oracle GoldenGate starts all groups of the specified process type that satisfy the wildcard on the local system, except those in `PASSIVE` mode.

**Example**

```
AUTOSTART ER *
```
BATCHSQL

Valid For

Replicat

Description

Use the BATCHSQL parameter to increase the performance of Replicat. BATCHSQL causes Replicat to organize similar SQL statements into arrays and apply them at an accelerated rate. In its normal mode, Replicat applies one SQL statement at a time.

BATCHSQL is valid for:
- DB2 for i (except V5R4 or i6.1)
- DB2 LUW
- DB2 on z/OS
- Oracle
- NonStop SQL/MX
- PostgreSQL
- SQL Server
- Teradata

How BATCHSQL Works

In BATCHSQL mode, Replicat organizes similar SQL statements into batches within a memory queue, and then it applies each batch in one database operation. A batch contains SQL statements that affect the same table, operation type (insert, update, or delete), and column list. For example, each of the following is a batch:

- Inserts to table A
- Inserts to table B
- Updates to table A
- Updates to table B
- Deletes from table A
- Deletes from table B

**Note:** Oracle GoldenGate analyzes foreign-key referential dependencies in the batches before executing them. If dependencies exist among statements that are in different batches, more than one SQL statement per batch might be required to maintain the referential integrity.

Controlling the Number of Cached Statements

The MAXSQLSTATEMENTS parameter controls the number of statements that are cached. See "MAXSQLSTATEMENTS" on page 3-197 for more information. Old statements are recycled using a least-recently-used algorithm. The batches are executed based on a specified threshold (see "Managing Memory").
Usage Restrictions
SQL statements that are treated as exceptions include:

- Statements that contain LOB or LONG data.
- Statements that contain rows longer than 25k in length.
- Statements where the target table has one or more unique keys besides the primary key. Such statements cannot be processed in batches because BATCHSQL does not guarantee the correct ordering for non-primary keys if their values could change.
- (SQL Server) Statements where the target table has a trigger.
- Statements that cause errors.

When Replicat encounters exceptions in batch mode, it rolls back the batch operation and then tries to apply the exceptions in the following ways, always maintaining transaction integrity:

- First Replicat tries to use normal mode: one SQL statement at a time within the transaction boundaries that are set with the GROUPTRANSOPS parameter. See “GROUPTRANSOPS” on page 3-160 for more information.
- If normal mode fails, Replicat tries to use source mode: apply the SQL within the same transaction boundaries that were used on the source.

When finished processing exceptions, Replicat resumes BATCHSQL mode.

<table>
<thead>
<tr>
<th>Source Transactions (Assumes same table and column list)</th>
<th>Replicat Transaction in Normal Mode</th>
<th>Replicat Transaction in BATCHSQL Mode</th>
<th>Replicat Transactions in Source Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transaction 1:</td>
<td>INSERT</td>
<td>INSERT (x3)</td>
<td>Transaction 1: INSERT</td>
</tr>
<tr>
<td>INSERT</td>
<td>DELETE</td>
<td>DELETE (x3)</td>
<td>INSERT</td>
</tr>
<tr>
<td>DELETE</td>
<td>INSERT</td>
<td>DELETE</td>
<td>DELETE</td>
</tr>
<tr>
<td>Transaction 2:</td>
<td>DELETE</td>
<td>INSERT</td>
<td>Transaction 2: INSERT</td>
</tr>
<tr>
<td>INSERT</td>
<td>INSERT</td>
<td>DELETE</td>
<td>INSERT</td>
</tr>
<tr>
<td>DELETE</td>
<td>DELETE</td>
<td>DELETE</td>
<td>DELETE</td>
</tr>
<tr>
<td>Transaction 3:</td>
<td>INSERT</td>
<td>INSERT</td>
<td>Transaction 3: INSERT</td>
</tr>
<tr>
<td>INSERT</td>
<td>DELETE</td>
<td>DELETE</td>
<td>INSERT</td>
</tr>
</tbody>
</table>

When to Use BATCHSQL
When Replicat is in BATCHSQL mode, smaller row changes will show a higher gain in performance than larger row changes. At 100 bytes of data per row change, BATCHSQL has been known to improve the performance of Replicat by up to 300 percent, but actual performance benefits will vary, depending on the mix of operations. At around 5,000 bytes of data per row change, the benefits of using BATCHSQL diminish.

Managing Memory
The gathering of SQL statements into batches improves efficiency but also consumes memory. To maintain optimum performance, use the following BATCHSQL options:

BATCHESPERQUEUE
BYTESPERQUEUE
As a benchmark for setting values, assume that a batch of 1,000 SQL statements at 500 bytes each would require less than 10 megabytes of memory.

**Default**

Disabled (Process in normal Replicat mode)

**Syntax**

```
BATCHSQL
[BATCHERRORMODE | NOBATCHERRORMODE]
[BATCHESPERQUEUE n]
[BATCHTRANSOPS n]
[BYTESPERQUEUE n]
[OPSPERBATCH n]
[OPSPERQUEUE n]
[THREADS (threadID[, threadID][,...][, thread_range[, thread_range][,...]])]
[TRACE]
```

**BATCHERRORMODE**

Causes Replicat to try to resolve errors without leaving BATCHSQL mode. It converts inserts that fail on duplicate-record errors to updates, and it ignores missing-record errors for deletes. When using BATCHERRORMODE, use the HANDLECOLLISIONS parameter to prevent Replicat from abending.

**NOBATCHERRORMODE**

The default, causes Replicat to disable BATCHSQL processing temporarily when there is an error, and then retry the transaction first in normal mode and then, if normal mode fails, in source mode (same transaction boundaries as on the source).

**BATCHESPERQUEUE n**

Controls the maximum number of batches that one memory queue can contain. After BATCHESPERQUEUE is reached, a target transaction is executed.

- Minimum value is 1.
- Maximum value is 1000.
- Default is 50.

**BATCHTRANSOPS n**

Controls the maximum number of batch operations that can be grouped into a transaction before requiring a commit. When BATCHTRANSOPS is reached, the operations are applied to the target.

- Minimum value is 1.
- Maximum value is 100000.
- Default is 1000 for nonintegrated Replicat (all database types) and 50 for an integrated Oracle Replicat.

**BYTESPERQUEUE n**

Sets the maximum number of bytes that one queue can contain. After BYTESPERQUEUE is reached, a target transaction is executed.
- Minimum value is 1000000 bytes (1 megabyte).
- Maximum value is 1000000000 bytes (1 gigabyte).
- Default is 2000000 bytes (20 megabytes).

**OPSPERBATCH n**
Sets the maximum number of row operations that one batch can contain. After OPSPERBATCH is reached, a target transaction is executed.
- Minimum value is 1.
- Maximum value is 100000.
- Default is 1200.

**OPSPERQUEUE n**
Sets the maximum number of row operations in all batches that one queue can contain. After OPSPERQUEUE is reached, a target transaction is executed.
- Minimum value is 1.
- Maximum value is 100000.
- Default is 1200.

**THREADS**
Valid for BATCHESPERQUEUE, BATCHTRANSOPS, and BYTESPERQUEUE. Applies these options to the specified thread or threads of a coordinated Replicat.
- `threadID[, threadID][, ...][, thread_range[, thread_range][, ...]]`
- Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.
- `[, thread_range[, thread_range][, ...]]`
- Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

**TRACE**
Enables detailed tracing of BATCHSQL activity to the console and to the report file. Do not set tracing without the guidance of an Oracle Support analyst.

**Example**

```
BATCHSQL BATCHESPERQUEUE 100, OPSPERBATCH 2000
```
BEGIN

Valid For

Replicat

Description

Use the \texttt{BEGIN} parameter to direct Replicat to start processing at the first record in the Oracle GoldenGate trail that has a timestamp greater than, or equal to, the time specified with \texttt{BEGIN}. All subsequent records, including records where the timestamp is less than the specified time, are processed. Use \texttt{BEGIN} when \texttt{SPECIALRUN} is specified for the same Replicat group.

Default

None

Syntax

\texttt{BEGIN \textit{date}[\textit{time}]}

\textit{date}[\textit{time}]

Specifies a time at which to begin processing. Valid values are a date and optional time in the format of \texttt{yyyy-mm-dd[ hh:mm[:ss[.cccccc]]]} based on a 24-hour clock. Seconds and centiseconds are optional.

Example

\texttt{BEGIN 2011-01-01 04:30:00}
This parameter is an alias for LOBMEMORY. See "LOBMEMORY" on page 3-182 for more information.
**BOOTDELAYMINUTES**

**Valid For**

Manager

**Description**

Use the `BOOTDELAYMINUTES` parameter on a Windows system to delay the activities that Manager performs when it starts, such as executing parameters. For example, `BOOTDELAYMINUTES` can be used to delay `AUTOSTART` parameters until database services are started.

Specify `BOOTDELAYMINUTES` before other parameter entries. This parameter only supports Windows.

**Default**

None (no delay)

**Syntax**

`BOOTDELAYMINUTES minutes`

*minutes*

The number of minutes to delay after system startup before starting Oracle GoldenGate processing.

**Example**

`BOOTDELAYMINUTES 5`
**Valid For**

Extract (Oracle only)

**Description**

Use the BR parameter to control the Bounded Recovery (BR) feature. This feature currently supports Oracle databases.

Bounded Recovery is a component of the general Extract checkpointing facility. It guarantees an efficient recovery after Extract stops for any reason, planned or unplanned, no matter how many open (uncommitted) transactions there were at the time that Extract stopped, nor how old they were. Bounded Recovery sets an upper boundary for the maximum amount of time that it would take for Extract to recover to the point where it stopped and then resume normal processing.

---

**Caution:** Before changing this parameter from its default settings, contact Oracle Support for guidance. Most production environments will not require changes to this parameter. You can, however, specify the directory for the Bounded Recovery checkpoint files without assistance.

---

**How Extract Recovers Open Transactions**

When Extract encounters the start of a transaction in the redo log (in Oracle, this is the first executable SQL statement) it starts caching to memory all of the data that is specified to be captured for that transaction. Extract must cache a transaction even if it contains no captured data, because future operations of that transaction might contain data that is to be captured.

When Extract encounters a commit record for a transaction, it writes the entire cached transaction to the trail and clears it from memory. When Extract encounters a rollback record for a transaction, it discards the entire transaction from memory. Until Extract processes a commit or rollback, the transaction is considered *open* and its information continues to be collected.

If Extract stops before it encounters a commit or rollback record for a transaction, all of the cached information must be recovered when Extract starts again. This applies to all transactions that were open at the time that Extract stopped.

Extract performs this recovery as follows:

- If there were no open transactions when Extract stopped, the recovery begins at the current Extract read checkpoint. This is a normal recovery.

- If there were open transactions whose start points in the log were very close in time to the time when Extract stopped, Extract begins recovery by re-reading the logs from the *beginning of the oldest open transaction*. This requires Extract to do redundant work for transactions that were already written to the trail or discarded before Extract stopped, but that work is an acceptable cost given the relatively small amount of data to process. This also is considered a normal recovery.

- If there were one or more transactions that Extract qualified as *long-running open transactions*, Extract begins its recovery with a *Bounded Recovery*. 

---

*Oracle GoldenGate Parameters 3-33*
How Bounded Recovery Works

A transaction qualifies as long-running if it has been open longer than one Bounded Recovery interval, which is specified with the BRINTERVAL option of the BR parameter. For example, if the Bounded Recovery interval is four hours, a long-running open transaction is any transaction that started more than four hours ago.

At each Bounded Recovery interval, Extract makes a Bounded Recovery checkpoint, which persists the current state and data of Extract to disk, including the state and data (if any) of long-running transactions. If Extract stops after a Bounded Recovery checkpoint, it will recover from a position within the previous Bounded Recovery interval or at the last Bounded Recovery checkpoint, instead of processing from the log position where the oldest open long-running transaction first appeared.

The maximum Bounded Recovery time (maximum time for Extract to recover to where it stopped) is never more than twice the current Bounded Recovery checkpoint interval. The actual recovery time will be a factor of the following:

- the time from the last valid Bounded Recovery interval to when Extract stopped.
- the utilization of Extract in that period.
- the percent of utilization for transactions that were previously written to the trail. Bounded Recovery processes these transactions much faster (by discarding them) than Extract did when it first had to perform the disk writes. This constitutes most of the reprocessing that occurs for transactional data.

When Extract recovers, it restores the persisted data and state that were saved at the last Bounded Recovery checkpoint (including that of any long running transactions).

For example, suppose a transaction has been open for 24 hours, and suppose the Bounded Recovery interval is four hours. In this case, the maximum recovery time will be no longer than eight hours worth of Extract processing time, and is likely to be less. It depends on when Extract stopped relative to the last valid Bounded Recovery checkpoint, as well as Extract activity during that time.

Advantages of Bounded Recovery

The use of disk persistence to store and then recover long-running transactions enables Extract to manage a situation that rarely arises but would otherwise significantly (adversely) affect performance if it occurred. The beginning of a long-running transaction is often very far back in time from the place in the log where Extract was processing when it stopped. A long-running transaction can span numerous old logs, some of which might no longer reside on accessible storage or might even have been deleted. Not only would it take an unacceptable amount of time to read the logs again from the start of a long-running transaction but, since long-running transactions are rare, most of that work would be the redundant capture of other transactions that were already written to the trail or discarded. Being able to restore the state and data of persisted long-running transactions eliminates that work.

Bounded Recovery Example

The following diagram illustrates a timeline over which a series of transactions were started. It shows how long-running open transactions are persisted to disk after a specific interval and then recovered after a failure. It will help to understand the terminology used in the example:

- A persisted object is any object in the cache that was persisted at a Bounded Recovery checkpoint. Typically this is the transactional state or data, but the cache is also used for objects that are internal to Extract. These are all collectively referred to as objects.
- The **oldest non-persisted object** is the oldest open object in the cache in the interval that immediately precedes the current Bounded Recovery checkpoint. Typically this is the oldest open transaction in that interval. Upon the restart of Bounded Recovery, runtime processing resumes from the position of the oldest non-persisted object, which, in the typical case of transactions, will be the position in the redo log of that transaction.

**Figure 3–1  Sample Bounded Recovery Checkpoints**

![Sample Bounded Recovery Checkpoints Diagram]

In this example, the Bounded Recovery interval is four hours. An open transaction is persisted at the current Bounded Recovery checkpoint if it has been open for more than one Bounded Recovery interval from the current Bounded Recovery checkpoint.

**At BR Checkpoint n:**
- There are five open transactions: T(27), T(45), T(801), T(950), T(1024). All other transactions were either committed and sent to the trail or rolled back. Transactions are shown at their start points along the timeline.
- The transactions that have been open for more than one Bounded Recovery interval are T(27) and T(45). At **BR Checkpoint n**, they are persisted to disk.
- The oldest non-persisted object is T(801). It is not eligible to be persisted to disk, because it has not been open across at least one Bounded Recovery interval. As the oldest non-persisted object, its start position in the log is stored in the **BR Checkpoint n** checkpoint file. If Extract stops unexpectedly after **BR Checkpoint n**, it will recover to that log position and start to re-read the log there. If there is no oldest non-persisted object in the preceding Bounded Recovery interval, Extract will start re-reading the log at the log position of the current Bounded Recovery checkpoint.

**At BR Checkpoint n+1:**
- T(45) was dirtied (updated) in the previous Bounded Recovery interval, so it gets written to a new persisted object file. The old file will be deleted after completion of **BR Checkpoint n+1**.
- If Extract fails while writing **BR Checkpoint n+1** or at any time within that Bounded Recovery checkpoint interval between **BR Checkpoint n** and **BR Checkpoint n+1**, it will recover from **BR Checkpoint n**, the last valid checkpoint. The restart position for **BR Checkpoint n** is the start of the oldest non-persisted transaction, which is T(801). Thus, the worst-case recovery time is always no more than two Bounded Recovery intervals from the point where Extract stopped, in this case no more than eight hours.
At BR Checkpoint n+3000
- The system has been running for a long time. T(27) and T(45) remain the only persisted transactions. T(801) and T(950) were committed and written to the trail sometime before BR Checkpoint n+2999. Now, the only open transactions are T(208412) and T(208863).
- BR Checkpoint n+3000 is written.
- There is a power failure in the interval after BR Checkpoint n+3000.
- The new Extract recovers to BR Checkpoint n+3000. T(27) and T(45) are restored from their persistence files, which contain the state from BR Checkpoint n. Log reading resumes from the beginning of T(208412).

Managing Long-running Transactions
Oracle GoldenGate provides the following parameters and commands to manage long-running transactions:
- Use the WARNLONGTRANS parameter to specify a length of time that a transaction can be open before Extract generates a warning message that the transaction is long-running. Also use WARNLONGTRANS to control the frequency with which Oracle GoldenGate checks for long-running transactions. Note that this setting is independent of, and does not affect, the Bounded Recovery interval.
- Use the SEND EXTRACT command with the SKIPTRANS option to force Extract to skip a specified transaction.
- Use the SEND EXTRACT command with the FORCETRANS option to force Extract to write a specified transaction to the trail as a committed transaction.
- Use the TRANLOGOPTIONS parameter with the PURGEORPHANEDTRANSACTIONS option to enable the purging of orphaned transactions that occur when a node fails and Extract cannot capture the rollback.

About the Files that are Written to Disk
At the expiration of a Bounded Recovery interval, Extract always creates a Bounded Recovery checkpoint file. Should there be long-running transactions that require persistence, they each are written to their own persisted-object files. A persisted-object file contains the state and data of a single transaction that is persisted to disk.

Field experience has shown that the need to persist long running transactions is rare, and that the transaction is empty in most of those cases.

If a previously persisted object is still open and its state and/or data have been modified during the just-completed Bounded Recovery interval, it is re-persisted to a new persisted object file. Otherwise, previously persisted object files for open transactions are not changed.

It is theoretically possible that more than one persisted file might be required to persist a long-running transaction.

Note: The Bounded Recovery files cannot be used to recover the state of Extract if moved to another system, even with the same database, if the new system is not identical to the original system in all relevant aspects. For example, checkpoint files written on an Oracle 11g Solaris platform cannot be used to recover Extract on an Oracle 11g Linux platform.
Circumstances that Change Bounded Recovery to Normal Recovery

Most of the time, Extract uses normal recovery and not Bounded Recovery, the exception being the rare circumstance when there is a persisted object or objects. Certain abnormal circumstances may prevent Extract from switching from Bounded Recovery back to normal recovery mode. These include, but are not limited to, such occurrences as physical corruption of the disk (where persisted data is stored for long-running transactions), inadvertent deletion of the Bounded Recovery checkpoint files, and other actions or events that corrupt the continuity of the environment. There may also be more correctable reasons for failure.

In all but a very few cases, if Bounded Recovery fails during a recovery, Extract switches to normal recovery. After completing the normal recovery, Bounded Recovery is turned on again for runtime.

Bounded Recovery is not invoked under the following circumstances:

- The Extract start point is altered by CSN or by time.
- The Extract I/O checkpoint altered.
- The Extract parameter file is altered during recovery, such as making changes to the \texttt{TABLE} specification.

After completion of the recovery, Bounded Recovery will be in effect again for the next run.

What to Do if Extract Abends During Bounded Recovery

If Extract abends in Bounded Recovery, examine the error log to determine the reason. It might be something that is quickly resolved, such as an invalid parameter file or incorrect privileges on the directory that contains the Bounded Recovery files. In such cases, after the problem is fixed, Extract can be restarted with Bounded Recovery in effect.

If the problem is not correctable, restart Extract with the \texttt{BRRESET} command in GGSCI. Extract will recover in normal recovery mode and then turn on Bounded Recovery again.

Modifying the BR Parameter

Bounded Recovery is enabled by default with a default Bounded Recovery interval of four hours (as controlled with the \texttt{BRINTERVAL} option). This interval should be appropriate for most environments. Do not alter the \texttt{BR} parameter without first obtaining guidance from an Oracle support analyst. Bounded Recovery runtime statistics are available to help Oracle GoldenGate analysts evaluate the Bounded Recovery usage profile to determine the proper setting for \texttt{BRINTERVAL} in the unlikely event that the default is not sufficient.

Should you be requested to alter \texttt{BR}, be aware that the Bounded Recovery interval is a multiple of the regular Extract checkpoint interval. The Extract checkpoint is controlled by the \texttt{CHECKPOINTSECS} parameter. Thus, the \texttt{BR} parameter controls the ratio of the Bounded Recovery checkpoint to the regular Extract checkpoint. You might need to change both parameters, if so advised by your Oracle representative.

Supported Databases

This parameter applies to Oracle databases. For other databases, Extract recovers by reading the old logs from the start point of the oldest open transaction at the point of failure and does not persist long-running transactions.
Default

```
BR BRINTERVAL 4, BRDIR BR
```

Syntax

```
BR
[, BRDIR directory]
[, BRINTERVAL number {M | H}]
[, BRKEEPSTALEFILES]
[, BROFF]
[, BROFFONFAILURE]
[, BRRESET]
[, BRFSOPTION { MS_SYNC | MS_ASYNC }]
```

**BRDIR directory**

Specifies the relative or full path name of the parent directory that will contain the BR directory. The BR directory contains the Bounded Recovery checkpoint files, and the name of this directory cannot be changed. The default parent directory for the BR directory is a directory named BR in the root directory that contains the Oracle GoldenGate installation files.

Each Extract group within a given Oracle GoldenGate installation will have its own sub-directory under the directory that is specified with BRDIR. Each of those directories is named for the associated Extract group.

For directory, do not use any name that contains the string `temp` or `tmp` (case-independent). Temporary directories are subject to removal during internal or external cleanup procedures.

**BRINTERVAL number {M | H}**

Specifies the time between Bounded Recovery checkpoints. This is known as the Bounded Recovery interval. This interval is an integral multiple of the standard Extract checkpoint interval, as controlled by the CHECKPOINTSECS parameter. However, it need not be set exactly. Bounded Recovery will adjust any legal BRINTERVAL parameter internally as it requires.

The minimum interval is 20 minutes. The maximum is 96 hours. The default interval is 4 hours.

**BRKEEPSTALEFILES**

Causes old Bounded Recovery checkpoint files to be retained. By default, only current checkpoint files are retained. Extract cannot recover from old Bounded Recovery checkpoint files. Retain old files only at the request of an Oracle support analyst.

**BROFF**

Turns off Bounded Recovery for the run and for recovery. Consult Oracle before using this option. In most circumstances, when there is a problem with Bounded Recovery, it turns itself off.

**BROFFONFAILURE**

Disables Bounded Recovery after an error. By default, if Extract encounters an error during Bounded Recovery processing, it reverts to normal recovery, but then enables Bounded Recovery again after recovery completes. BROFFONFAILURE turns Bounded Recovery off for the runtime processing.

**BRRESET**

BRRESET forces Extract to use normal recovery for the current run, and then turn Bounded Recovery back on after the recovery is complete. Its purpose is for the rare
cases when Bounded Recovery does not revert to normal recovery if it encounters an error. Bounded Recovery will be enabled during runtime. Consult Oracle Support before using this option.

To use this option, you must start Extract from the command line. To run Extract from the command line, use the following syntax:

```
replicat paramfile name.prm reportfile name.rpt
```

Where:

- `paramfile name.prm` is the relative or fully qualified name of the Extract parameter file. The command name can be abbreviated to `pf`.
- `reportfile name.rpt` is the relative or fully qualified name of the Extract report file, if you want it in a place other than the default. The command name can be abbreviated to `rf`.

**BR BRFSOPTION {MS_SYNC | MS_ASYNC}**

Performs synchronous/asynchronous writes of the mapped data in Bounded Recovery.

**MS_SYNC**

Bounded Recovery writes of mapped data are synchronized for I/O data integrity completion.

**MS_ASYNC**

Bounded Recovery writes of mapped data are initiated or queued for servicing.

**Example**

```
BR BRDIR /user/checkpt/br
```

specifies that the Bounded Recovery checkpoint files will be created in the `/user/checkpt/br` directory.
BULKLOAD

Valid For

Replicat

Description

Use the BULKLOAD parameter for an initial load Replicat when using the direct bulk load to Oracle SQL*Loader method. This method passes initial-load data directly to the interface of Oracle's SQL*Loader utility to perform a direct load. A Collector process and trails are not used.

For a complete guide to the methods of loading data with Oracle GoldenGate, see Administering Oracle GoldenGate for Windows and UNIX.

Default

None

Syntax

BULKLOAD
[LOGGING | NOLOGGING]
[PARALLEL | NOPARALLEL]
[SKIPALLINDEXES | SKIPUNUSEDINDEX | NOSKIPALLINDEXES]

LOGGING | NOLOGGING
Valid for Replicat for Oracle. LOGGING is the default and enables redo logging for the loaded objects. NOLOGGING increases BULKLOAD performance by disabling redo logging of the loaded objects. Do not specify NOLOGGING for cascading synchronization and multiple master configurations.

However, BULKLOAD must be set to LOGGING if the target is part of a cascading or bi-directional configuration, where a local Extract will capture the loaded objects.

PARALLEL | NOPARALLEL
Valid for Replicat for Oracle. PARALLEL enables BULKLOAD to use multiple load sessions to load the same segment concurrently. NOPARALLEL is the default and disables parallel loading.

SKIPALLINDEXES | SKIPUNUSEDINDEX | NOSKIPALLINDEXES
Valid for Replicat for Oracle. Controls the handling of indexes. NOSKIPALLINDEXES is the default, which allows index maintenance during a direct load. SKIPALLINDEXES skips all index maintenance. SKIPUNUSEDINDEX skips unusable indexes.
CACHEMGR

Valid For

Extract and Replicat, all databases except DB2 on z/OS

Description

Use the CACHEMGR parameter to control the amount of virtual memory and temporary disk space that is available for caching uncommitted transaction data.

Caution: Before changing this parameter from its default cache settings, contact Oracle Support for guidance. The cache manager of Oracle GoldenGate is internally self-configuring and self-adjusting, and most production environments will not require changes to this parameter. You can, however, specify the directory for the page files without assistance.

About Memory Management

Note: While described as accurately as possible here, the underlying design of the memory management component is always subject to changes that may be required by ongoing product improvements.

Because Oracle GoldenGate replicates only committed transactions, it stores the operations of each transaction in a managed virtual-memory pool known as a cache until it receives either a commit or a rollback for that transaction. One global cache operates as a shared resource of an Extract or Replicat process. The following sub-pools of virtual memory are allocated from the global cache:

- One sub-pool per Extract log reader thread or Replicat trail reader thread for most transaction row data.
- One sub-pool for BLOB data and possibly other large items.

Within each sub-pool, individual buffers are allocated from the global cache. Each buffer contains information that is relative to a transaction that is being processed by Oracle GoldenGate.

The Oracle GoldenGate cache manager takes advantage of the memory management functions of the operating system to ensure that Oracle GoldenGate processes work in a sustained and efficient manner. Within its cache, it makes use of modern virtual memory techniques by:

- Allocating and managing active buffers efficiently.
- Recycling old buffers instead of paging to disk, when possible.
- Paging less-used information to disk, when necessary.

The actual amount of physical memory that is used by any Oracle GoldenGate process is controlled by the operating system, not the Oracle GoldenGate program.

The cache manager keeps an Oracle GoldenGate process working within the soft limit of its global cache size, only allocating virtual memory on demand. (The cache manager does not allocate physical memory, over which it has no control.) System calls
to increase the cache size are made only as a last resort and, when used, are always followed by the release of virtual memory back to the system.

The system must have sufficient swap space for each Oracle GoldenGate Extract and Replicat process that will be running. To determine the required swap space:

1. Start one Extract process and one Replicat process.
2. Run GGSCI.
3. View the report file of each running process and find the line `PROCESS VM AVAIL FROM OS (min)`.
4. Round up each value to the next full gigabyte if needed. For example, round up 1.76GB to 2 GB.
5. Multiply the rounded-up Extract value by the number of Extract processes.
6. Multiply the rounded-up Replicat value by the number of Replicat processes.
7. Add the two results, plus any additional swap space required by other Oracle GoldenGate processes and other processes on the system.

\[(\text{PROCESS VM} \times \text{number}_\text{Extracts}) + (\text{PROCESS VM} \times \text{number}_\text{Replicats}) + (\text{swap}_\text{for}_\text{other}_\text{processes}) = \text{max}_\text{swap}_\text{space}_\text{on}_\text{system}\]

This sum is the maximum amount of swap space that could be needed for those processes. The actual amount of physical memory that is used by any Oracle GoldenGate process is controlled by the operating system, not the Oracle GoldenGate process. The global cache size is controlled by the `CACHESIZE` option of `CACHEMGR`.

---

**Note:** The cache manager is also used internally by Oracle GoldenGate for other purposes besides the BLOB sub-pool and the sub-pool for other transaction data. You may see these additional memory pools when you view the statistics.

---

**When to Adjust CACHEMGR**

The memory manager generates statistics that can be viewed with the `SEND EXTRACT` or `SEND REPLICAT` command when used with the `CACHEMANAGER` option. The statistics show the size of the memory pool, the paging frequency, the size of the transactions, and other information that creates a system profile.

Based on this profile, you might need to make adjustments to the memory cache if you see performance problems that appear to be related to file caching. The first step is to modify the `CACHESIZE` parameter. You might need to use a higher or lower cache size based on the size and type of transactions that are being generated.

It is possible, however, that operating system constraints could limit the effect of modifying any components of the `CACHEMGR` parameter. In particular, if the operating system has a small per-process virtual memory limit, it will force more file caching, regardless of the `CACHEMGR` configuration.

See "SEND EXTRACT" on page 1-37 and "SEND REPLICAT" on page 1-72 for more information.

**Viewing Basic Statistics in the Report File**

Upon completing its initialization, the cache manager writes the following statistics to the process report file:
CACHEMGR virtual memory values (may have been adjusted)
CACHESIZE: 32G
CACHEPAGEOUTSIZE (normal): 8M
PROCESS VM AVAIL FROM OS (min): 63.97G
CACHESIZEMAX (strict force to disk): 48G

Where:
- **CACHESIZE** shows the soft limit of virtual memory that is available to the process for caching transaction data. It is determined dynamically, based on the value of **PROCESS VM AVAIL FROM OS (min)**. It can be controlled with the **CACHESIZE** option of **CACHEMGR**.
- **PROCESS VM AVAIL FROM OS (min)** shows the approximate amount of virtual memory that the process has determined it can use. For internal reasons, this amount may be less than what the operating system shows as being available.
- **CACHESIZEMAX (strict force to disk)** is derived from **PROCESS VM AVAIL FROM OS** and **CACHESIZE**. It can be understood in terms of how the cache manager determines which transactions are eligible to be paged out to disk. Normally, only those whose current virtual memory buffers exceed a specific internal value are eligible to be paged. When the total memory requested exceeds **CACHESIZE**, the cache manager looks for transactions to write to disk and chooses them from the list of eligible ones. If the eligible ones have been paged to disk already, and the virtual memory in use now exceeds **CACHESIZEMAX (strict force to disk)**, then any transaction that requires additional buffers can be eligible for paging. This guarantees that virtual memory will always be available.

**Identifying the Paging Directory**
By default, Oracle GoldenGate maintains data that it swaps to disk in the `dirtmp` sub-directory of the Oracle GoldenGate installation directory. The cache manager assumes that all of the free space on the file system is available. This directory can fill up quickly if there is a large transaction volume with large transaction sizes. To prevent I/O contention and possible disk-related Extract failures, dedicate a disk to this directory. You can assign a name and size to this directory with the **CACHEDIRECTORY** option of the **CACHEMGR** parameter. The **CACHESIZE** option of **CACHEMGR** sets a soft limit for the amount of virtual memory (cache size) that is available for caching transaction data.

**Guidelines for Using CACHEMGR**
- This parameter is valid for all databases supported by Oracle GoldenGate.
- At least one argument must be supplied. **CACHEMGR** by itself is invalid.
- Parameter options can be listed in any order.
- Only one **CACHEMGR** parameter is permitted in a parameter file.
- To use this parameter correctly (other than specifying the directory for the page files), you must know the profile of the system and the kinds of transactions that are being propagated from your applications. In normal environments, you should not need to change this parameter, because the cache manager is self-adjusting. If you feel that an adjustment is warranted, please open an Oracle service request at http://support.oracle.com.

**Default**
None
Syntax

CACHEMGR {
    [, CACHESIZE size]
    [, CACHEDIRECTORY path [size] [,...]]
}

CACHESIZE size
Sets a soft limit for the amount of virtual memory (cache size) that is available for
caching transaction data. On 64-bit systems, the default is 64 GB. On 32-bit systems,
the cache size is determined dynamically by the cache manager.

The memory is allocated on demand. By default, the cache manager dynamically
determines the amount of virtual memory that is available to it from the operating
system and determines the appropriate cache size. The available virtual memory is
reported with the PROCESS VM AVAIL FROM OS value in the report file. The CACHESIZE
value will be sized down if it is larger than, or sufficiently close to, the amount of
virtual memory that is available to the process. However, for systems with large
address spaces, the cache manager does no further determination once an internal
limit is reached.

The CACHESIZE value will always be a power of two, rounded down from the value of
PROCESS VM AVAIL FROM OS, unless the latter is itself a power of two, in which case it
is halved. After the specified size is consumed by data, the memory manager will try
to free up memory by paging data to disk or by reusing aged buffers, before
requesting more memory from the system.

If a transaction's cache virtual memory requirements grow beyond the initial buffer
allocation, the additional amount of cache memory that is allocated by the cache
manager is determined dynamically based on factors such as the current size of the
cached data of this transaction, the size needed for the new data, and the amount of
virtual memory that is being used conjointly by all the transactions.

CACHEDIRECTORY path [size]
Specifies the name of the directory to which Oracle GoldenGate writes transaction
data to disk temporarily when necessary. The default without this parameter is the
dirtmp sub-directory of the Oracle GoldenGate installation directory. Any directory for
temporary files can be on an Oracle Database File System, but cannot be on a direct
I/O or concurrent I/O mounted file system that does not support the mmap() system
call, such as AIX.

- path is a fully qualified directory name.
- size sets a maximum amount of disk space that can be allocated to the specified
directory. The upper limit is that which is imposed by the file system, such as
maximum file size or number of files. The minimum size is 2 GB, which is
enforced. There is no default. Do not use this option unless you must constrain the
swap space that is used by Oracle GoldenGate because of resource limitations.

You can specify more than one directory by using a CACHEDIRECTORY clause for each
one. The maximum number of directories is 100.

The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in
any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

CACHEMGR CACHEFSOPTION { MS_SYNC | MS_ASYNC }
Performs synchronous or asynchronous writes of the mapped data in the Oracle
GoldenGate memory cache manager.
Example

CACHEMGR CACHESIZE 500MB, CACHEDIRECTORY /ggs/temp 2GB, CACHEDIRECTORY /ggs2/temp 2GB
# CATALOGEXCLUDE

**Valid For**

Extract, Replicat, DEFGEN

**Description**

Use the `CATALOGEXCLUDE` parameter to explicitly exclude source objects in the specified container or catalog from the Oracle GoldenGate configuration when the container or catalog name is being specified with a wildcard in `TABLE` or `MAP` statements. This parameter is valid when the database is an Oracle container database or a SQL/MX database, where fully qualified three-part names are being used.

The positioning of `CATALOGEXCLUDE` in relation to parameters that specify files or trails determines its effect. Parameters that specify trails or files are: `EXTFILE`, `RMTFILE`, `EXTTRAIL`, `RMTTRAIL`. The parameter works as follows:

- **When a `CATALOGEXCLUDE` specification is placed before any `TABLE` or `SEQUENCE` parameters, and also before the parameters that specify trails or files, it applies globally to all trails or files, and to all `TABLE` and `SEQUENCE` parameters.**
- **When a `CATALOGEXCLUDE` specification is placed after a parameter that specifies a trail or file, it is effective only for that trail or file and only for the `TABLE` or `SEQUENCE` parameters that are associated with it. Multiple trail or file specifications can be made in a parameter file, each followed by a set of `TABLE`, `SEQUENCE`, and `CATALOGEXCLUDE` specifications.**

`CATALOGEXCLUDE` is evaluated before evaluating the associated `TABLE` or `SEQUENCE` parameter. Thus, the order in which they appear does not make a difference.

See also the `EXCLUDEWILDCARDOBJECTSONLY` parameter.

**Default**

None

**Syntax**

```
CATALOGEXCLUDE {container | catalog}
```

*container | catalog*

The source Oracle container or SQL/MX catalog that is to be excluded. A wildcard can be used. Follow the rules for using wildcards described in *Administering Oracle GoldenGate for Windows and UNIX*.

**Examples**

**Example 1**

This example omits all source catalogs that contain the string `src_test`.

```
EXTRACT capt
RMTHOST sysb, MGRPORT 7809
RMTTRAIL /ggs/dirdat/aa
CATALOGEXCLUDE src_test*
TABLE *.*.*;
```
Example 2
This example omits the pdb1 pluggable database.

EXTRACT capt
USERIDALIAS alias1
RMTHOST sysb, MGRPORT 7809
RMTTRAIL /ggs/dirdat/aa
CATALOGEXCLUDE pdb1
TABLE *.*.*;
CHARMAP

Valid For

Replicat

Description

Use the CHARMAP parameter to specify that the character mapping file overrides the character code point mapping. By enabling character set conversion for same character sets, you may encounter performance degradation.

Placement in the Parameter File

CHARMAP must be placed on the first line of the parameter file.

Default

The encoding of the parameter file is operating system default character set.

Syntax

CHARMAP charmap filename

The character mapping file format is as follows:

-- Sample character mapping file.
-- Can use -- or COMMENT as comment line.
-- Can use CHARSET parameter to specify file encoding.
--
-- Source character set
SOURCECHARSET     shiftjis
--
-- Target character set
TARGETCHARSET     ja16euc
--
-- Character map definition by one code point.
-- left hand is source and right hand target code point.
\xa2c1     \x89\xa2\xb7        -- override \xa2c1 to \x89\xa2\xb7
--
-- Character map definition by range. Number of source and target
characters must be the same.
\x61 - \x7a    \x41 - \x5a

Example

In the following example, the character map definition is given by range (the number of source and target characters must be the same):

CHARMAP \x41 - \x5a

REPLACEBADCHAR FORCECHECK

This enables strict character set conversion and check code point even if the source and target are the same.

Add the following to your character mapping file:

SOURCECHARSET    windows-932
TARGETCHARSET    windows-932
CHARSET

Valid For

Extract, Replicat, DEFGEN, Manager, GLOBALS

Description

Use the CHARSET parameter to specify the character set of the parameter files in the local Oracle GoldenGate instance. By default, the parameter file is created in the default character set of the local operating system. CHARSET specifies an alternative character set to use in the event that the local platform does not support a required character or characters.

CHARSET allows operating-system incompatible characters, including multi byte characters, to be used in the parameter file without the need for an escape sequence (\uXXXX) when the local platform does not support multibyte characters as the default character set of the operating system.

CHARSET can also be used when the parameter file is being created on one system but will be used on a different system with a different character set. To avoid possible incompatibilities between different character sets, you should create parameter files on the same system where they will be used by Oracle GoldenGate.

---

**Note:** Use of CHARSET in the mgr.prm file is not supported in 12.1.2.x or earlier releases.

---

Placement in the Parameter File

CHARSET must be placed on the first line of the parameter file.

Usage in the GLOBALS File

CHARSET in a GLOBALS file sets a default character set for the parameter files of all local processes. CHARSET in an individual parameter file overrides the default that is set in GLOBALS.

Usage in Nested Parameter Files

You can use CHARSET in a parameter file that includes an OBEY or INCLUDE parameter, but the referenced parameter file does not inherit the CHARSET character set. The CHARSET character set is used to read wildcarded object names in the referenced file, but you must use an escape sequence (\uXXXX) to specify all other incompatible characters in the referenced file.

Default

None

Syntax

CHARSET character_set

**character_set**
Any supported character set.
Example

CHARSET UTF-8
CHECKMINUTES

Valid For
Manager

Description
Use the CHECKMINUTES parameter to control how often Manager performs maintenance activities. Decreasing this parameter can significantly affect performance if trail files roll over frequently. Other events, such as processes ending abnormally, also trigger the maintenance cycle.

Default
Every 10 minutes

Syntax
CHECKMINUTES minutes

minutes
The frequency, in minutes, to perform maintenance activities.

Example
CHECKMINUTES 15
CHECKPARAMS

Valid For

Extract and Replicat

Description

Use the CHECKPARAMS parameter to test the syntax of a parameter file. To start the test:

1. Edit the parameter file to add CHECKPARAMS.
2. (Optional) To verify the tables, add the NODYNAMICRESOLUTION parameter.
3. Start the process. Without processing data, Oracle GoldenGate audits the syntax. If NODYNAMICRESOLUTION exists, Oracle GoldenGate connects to the database to verify that the tables specified with TABLE or MAP exist. If there is a syntax failure, the process abends with error 190. If the syntax succeeds, the process stops and writes a message to the report file that the parameters processed successfully.
4. Do one of the following:
   - If the test succeeds, edit the file to remove the CHECKPARAMS parameter and the NODYNAMICRESOLUTION parameter, if used, and then start the process again to begin processing.
   - If the test fails, edit the parameter file to fix the syntax based on the report's findings, and then remove NODYNAMICRESOLUTION and start the process again.

CHECKPARAMS can be positioned anywhere within the parameter file.

Default

None

Syntax

CHECKPARAMS
CHECKPOINTSECS

Valid For

Extract and Replicat

Description

Use the CHECKPOINTSECS parameter to control how often Extract and Replicat make their routine checkpoints.

- Decreasing the value causes more frequent checkpoints. This reduces the amount of data that must be reprocessed if the process fails, but it could cause performance degradation because data is written to disk more frequently.

- Increasing the value causes less frequent checkpoints. This might improve performance, but it increases the amount of data that must be reprocessed if the process fails. When using less frequent Extract checkpoints, make certain that the transaction logs remain available in case the data has to be reprocessed.

| Note: | In addition to its routine checkpoints, Replicat also makes a checkpoint when it commits a transaction. |

Avoid changing CHECKPOINTSECS unless you first open an Oracle service request.

Default

10 seconds

Syntax

CHECKPOINTSECS seconds

seconds

The number of seconds to wait before issuing a checkpoint.

Example

CHECKPOINTSECS 20
CHECKPOINTTABLE

Valid For

GLOBALS

Description

Use the CHECKPOINTTABLE parameter in a GLOBALS parameter file to specify the name of a default checkpoint table that can be used by all Replicat groups in one or more Oracle GoldenGate instances. All Replicat groups created with the ADD REPLICAT command will default to this table unless it is overridden by using the CHECKPOINTTABLE option of that command.

To create the checkpoint table, use the ADD CHECKPOINTTABLE command in GGSCI. Do not use a checkpoint table for a Replicat that is configured in integrated mode against an Oracle target database. It is not required in that mode and will be ignored.

See Administering Oracle GoldenGate for Windows and UNIX for more information about creating a checkpoint table.

Default

None

Syntax

CHECKPOINTTABLE [container. | catalog.] owner.table

[container. | catalog.]owner.table
The owner and name of the checkpoint table. Additionally, for an Oracle container database, specify the correct pluggable database (container). For a SQL/MX database, specify the correct catalog.

Example

CHECKPOINTTABLE finance.ggs.chkpt
CMDTRACE

Valid For

Extract and Replicat

Description

Use the CMDTRACE parameter to display macro expansion steps in the report file. You can use this parameter more than once in the parameter file to set different options for different macros.

Default

OFF

Syntax

CMDTRACE \{ON | OFF | DETAIL\}

ON
Enables the display of macro expansion.

OFF
Disables the display of macro expansion.

DETAIL
Produces a verbose display of macro expansion.

Example

In the following example, tracing is enabled before #testmac is invoked, and then disabled after the macro's execution.

MACRO #testmac
BEGIN
col1 = col2,
col3 = col4
END;
...
CMDTRACE ON
MAP test.table2 , TARGET test.table2,
COLMAP (#testmac);
CMDTRACE OFF
COLMATCH

Valid For
Extract and Replicat

Description
Use the COLMATCH parameter to create global rules for column mapping. COLMATCH rules apply to all TABLE or MAP statements that follow the COLMATCH statement. Global rules can be turned off for subsequent TABLE or MAP entries with the RESET option.

With COLMATCH, you can map between tables that are similar in structure but have different column names for the same sets of data. COLMATCH provides a more convenient way to map columns of this type than does using a COLMAP clause in individual TABLE or MAP statements.

With COLMATCH, you can:
- Map explicitly based on column names.
- Ignore name prefixes or suffixes.

Either COLMATCH or a COLMAP clause of a TABLE or MAP statement is required when mapping differently named source and target columns.

See Administering Oracle GoldenGate for Windows and UNIX for more information about mapping columns.

Default
None

Syntax
COLMATCH
(NAMES target_column = source_column | PREFIX prefix | SUFFIX suffix | RESET)

NAMES target_column = source_column
Specifies the name of a target and source column, for example CUSTOMER_CODE and CUST_CODE. If the database requires double quotes to enforce case-sensitivity, specify the column name that way. For example: NAMES "ABC" = "ABC2". For other case-sensitive databases, specify the column name as it is stored in the database, for example: NAMES ABC = abc.

PREFIX prefix | SUFFIX suffix
Specifies a column name prefix or suffix to ignore. If the database requires double quotes to enforce case-sensitivity, specify the prefix or suffix that way if it is case-sensitive. For other case-sensitive databases, specify the prefix or suffix as it is stored in the database.

For example, to map a target column named "ORDER_ID" to a source column named "P_ORDER_ID", specify:

COLMATCH PREFIX 'P_'
To map a target column named \texttt{"CUST\_CODE\_K"} to a source column named \texttt{CUST\_CODE}, specify:

\begin{verbatim}
COLMATCH SUFFIX "\_K"
\end{verbatim}

\textbf{RESET}
Turns off previously defined COLMATCH rules for subsequent TABLE or MAP statements.

\section*{Examples}

\textbf{Example 1}
\begin{verbatim}
COLMATCH NAMES "CUSTOMER\_CODE" = "CUST\_CODE"
\end{verbatim}

\textbf{Example 2}
\begin{verbatim}
COLMATCH NAMES Customer_Code = 'Cust_Code'
\end{verbatim}

\textbf{Example 3}
\begin{verbatim}
COLMATCH PREFIX P_
\end{verbatim}

\textbf{Example 4}
\begin{verbatim}
COLMATCH SUFFIX _K
\end{verbatim}

\textbf{Example 5}
\begin{verbatim}
COLMATCH RESET
\end{verbatim}
Valid For

Manager, Extract, Replicat

Description

Use the COMMENT parameter or double hyphens (--) to indicate comments anywhere within a parameter file. Anything on the same line after COMMENT or double hyphens is ignored during processing. Comments that continue to the next line must be preceded by another COMMENT keyword or double hyphens.

---

**Note:** If any columns in the tables that are being synchronized contain the word "comment," there may be conflicts with the COMMENT parameter. Use double hyphens instead.

---

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about working with parameter files.

Default

None

Syntax

{(COMMENT comment) | (--) comment}

Examples

**Example 1**

COMMENT GoldenGate param file for fin Extract group.

**Example 2**

-- GoldenGate param file for fin Extract group.
COMPRESSDELETES | NOCOMPRESSDELETES

Valid For

Extract

Description

Use the COMPRESSDELETES and NOCOMPRESSDELETES parameters to control the way that columns are written to the trail record for DELETE operations. COMPRESSDELETES and NOCOMPRESSDELETES can be used globally for all TABLE statements in the parameter file, or they can be used as on-off switches for individual TABLE statements.

These parameters support the following databases:

- DB2 LUW
- DB2 z/OS
- Oracle
- SQL/MX
- SQL Server
- Sybase
- Teradata version 12 or later

These parameters do not affect data pumps.

Default

COMPRESSDELETES

Syntax

{COMPRESSDELETES | NOCOMPRESSDELETES [FETCHMISSINGCOLUMNS]}

COMPRESSDELETES

Causes Extract to write only the primary key to the trail for DELETE operations. This is the default. The key provides enough information to delete the correct target record, while restricting the amount of data that must be processed.

NOCOMPRESSDELETES [FETCHMISSINGCOLUMNS]

NOCOMPRESSDELETES sends all of the columns to the trail. This becomes the default when a table definition does not include a primary key or unique index, or when a substitute key is defined with the KEYCOLS option of TABLE. The KEYCOLS option writes the specified columns to the trail whether or not a real key exists. See KEYCOLS (columns) for more information about the KEYCOLS option.

NOCOMPRESSDELETES is also required when using the Conflict Detection and Resolution (CDR) feature for a DB2 database on any of the platforms that are supported by Oracle GoldenGate. See Administering Oracle GoldenGate for Windows and UNIX for more information about CDR.

FETCHMISSINGCOLUMNS is valid for Oracle Database only. It causes the values of data types that are only supported by fetching to be fetched from the database on DELETE operations. These data types are LOB, UDT, LONG, and some XMLType columns. For
detailed information about columns that are supported by fetching (rather than directly captured from the redo stream), see Installing and Configuring Oracle GoldenGate for Oracle Database. The columns that are fetched will appear in the trail file as part of the DELETE record. If NOCOMPRESSDELETES is used for Oracle Database data without the FETCHMISSINGCOLUMNS option, only the LOB data that can be read from the logs (without fetching) will be included in the DELETE operation in the trail.
COMPRESSUPDATES | NOCOMPRESSUPDATES

Valid For

Extract

Description

Use the COMPRESSUPDATES and NOCOMPRESSUPDATES parameters for Extract to control the way columns are written to the trail record for UPDATE operations.

COMPRESSUPDATES, the default, causes Extract to write only the primary key and the changed columns of a row to the trail for update operations. This provides enough information to update the correct target record (unless conflict resolution is required), while restricting the amount of data that must be processed.

If other columns are supplementally logged by the database for use by Oracle GoldenGate, Extract writes those columns to the trail as well. Additionally, if a substitute key is defined with the KEYCOLS option of the TABLE parameter, those columns are written to the trail, whether or not a primary or unique key is defined. See "KEYCOLS (columns)" on page 3-331 for more information.

NOCOMPRESSUPDATES sends all of the columns to the trail. This becomes the default when a table definition does not include a primary key or unique index. NOCOMPRESSUPDATES also is required when using the Conflict Detection and Resolution (CDR) feature for a DB2 database on any of the platforms that are supported by Oracle GoldenGate. See Administering Oracle GoldenGate for Windows and UNIX for more information about CDR.

COMPRESSUPDATES and NOCOMPRESSUPDATES apply globally for all TABLE statements in a parameter file.

These parameters support the following databases:

- DB2 LUW
- DB2 z/OS
- Teradata version 12 or later
- SQL Server
- Sybase

COMPRESSUPDATES and NOCOMPRESSUPDATES do not affect data pumps.

Default

COMPRESSUPDATES

Syntax

COMPRESSUPDATES | NOCOMPRESSUPDATES
COORDSTATINTERVAL

Valid For

Replicat in coordinated mode

Description

Use the COORDSTATINTERVAL parameter to set the amount of time, in seconds, between requests for statistics sent by the Replicat coordinator thread to the apply threads. If a thread does not return statistics within an internal heartbeat interval, Replicat logs a warning message. The heartbeat interval is not configurable and is always six times the COORDSTATINTERVAL interval. At the default COORDSTATINTERVAL interval of 10 seconds, for example, the heartbeat default is one minute (60 seconds).

Default

10 seconds

Syntax

COORDSTATINTERVAL interval

interval

The interval, in seconds, between requests for thread statistics. Valid values are 0 or any positive number.
COORDTIMER

Valid For

Replicat in coordinated mode

Description

Use the COORDTIMER parameter to set a base amount of time, in seconds, that the threads and coordinator wait for each other to start. A thread will wait for this base time interval before retrying a connection to the coordinator and it will do this a certain number of times. The coordinator waits for the length of this base time interval and it is reset after every thread is successfully registered. The overall time the coordinator waits before abending is dependent on this timer and it is variable depending on the register time of the threads.

A value of 0 disables this timing procedure. If timing is disabled, the coordinator thread may wait indefinitely for the threads to start, and Replicat will enter a suspended state. In this case, the internal Replicat heartbeat timer is disabled regardless of the COORDSTATINTERVAL setting.

Default

180 seconds (three minutes)

Syntax

COORDTIMER wait_time

wait_time

The amount of time, in seconds, that the coordinator thread waits for the apply threads to start. Valid values are 0 or any positive number.
CREDENTIALSTORELOCATION

Valid For

GLOBALs

Description

Use the CREDENTIALSTORE parameter to change the location of the Oracle GoldenGate credential store from the default location. The default location is the dircrd directory in the Oracle GoldenGate installation directory. The default location is the preferred location.

The credential store stores database user names and passwords in encrypted format as a security measure. When CREDENTIALSTORE is used, the specified location is assumed for all GGSCI commands that manage the credential store. See “ADD CREDENTIALSTORE” on page 1-99 for more information about the credential store. See Administering Oracle GoldenGate for Windows and UNIX for more information about configuring Oracle GoldenGate security.

Syntax

CREDENTIALSTORELOCATION directory

directory
The full path name of the directory where the credential store is to be stored.

Example

CREDENTIALSTORELOCATION /home/ogg/credentials
CUSEREXIT

Valid For

Extract when fetching from a multitenant container database (CDB) and Replicat

Description

Use the CUSEREXIT parameter to call a custom exit routine written in C programming code from a Windows DLL or UNIX shared object at a defined exit point within Oracle GoldenGate processing. Your user exit routine must be able to accept different events and information from the Extract and Replicat processes, process the information as desired, and then return a response and information to the caller (the Oracle GoldenGate process that called it).

User exits can be used as an alternative to, or in conjunction with, the data transformation functions that are available within the Oracle GoldenGate solution.

Note: When using a coordinated Replicat to call a user exit routine, you are responsible for writing the user exits in a thread-safe manner.

For help with creating and implementing user exits, see Administering Oracle GoldenGate for Windows and UNIX.

Default

None

Syntax

CUSEREXIT {DLL | shared_object} routine
[, PASSTHRU]
[, INCLUDE_UPDATE_BEFOR]E
[, PARAMS 'string']

{DLL | shared_object}
The name of the Windows DLL or UNIX shared object that contains the user exit function.

routine
The name of the exit routine to be executed.

PASSTHRU
Valid only for an Extract data pump. It assumes that no database is required, and that no output trail is allowed. It expects that the user exit will perform all of the processing and that Extract will skip the record. Extract will perform all of the required data mapping before passing the record to the user exit.

Instead of a reply status of EXIT_OK_VAL, the reply will be EXIT_PROCESSED_REC_VAL. All process statistics are updated as if the records were processed by Oracle GoldenGate.

INCLUDE_UPDATE_BEFOR]E
Passes the before images of column values to a user exit. When using this parameter, you must explicitly request the before image by setting the requesting_before_after_ind flag to BEFORE_IMAGE_VAL within a callback function that supports this flag.
Otherwise, only the after image is passed to the user exit. By default, Oracle GoldenGate only works with after images.

When using INCLUDEUPDATEBEFORES for a user exit that is called from a data pump or from Replicat, always use the GETUPDATEBEFORES parameter for the primary Extract process, so that the before image is captured, written to the trail, and causes a process_record event in the user exit. In a case where the primary Extract also has a user exit, GETUPDATEBEFORES causes both the before image and the after image to be sent to the user exit as separate EXIT_CALL_PROCESS_RECORD events.

If the user exit is called from a primary Extract (one that reads the transaction log), only INCLUDEUPDATEBEFORES is needed for that Extract. GETUPDATEBEFORES is not needed in this case, unless other Oracle GoldenGate processes downstream will need the before image to be written to the trail. INCLUDEUPDATEBEFORES does not cause before images to be written to the trail.

PARAMS 'string'
Passes the specified string at startup. Can be used to pass a properties file, startup parameters, or other string. Enclose the string within single quote marks.

Data in the string is passed to the user exit in the EXIT_CALL_START exit_params_def.function_param. If no quoted string is specified with PARAMS, the exit_params_def.function_param is NULL.

Examples

Example 1
CUSEREXIT userexit.dll MyUserExit

Example 2
CUSEREXIT userexit.dll MyUserExit, PARAMS 'init.properties'

Example 3
CUSEREXIT userexit.dll MyUserExit, INCLUDEUPDATEBEFORES, PARAMS 'init.properties'

Example 4
CUSEREXIT userexit.dll MyUserExit, INCLUDEUPDATEBEFORES, PASSTHRU, &
PARAMS 'init.properties'

Example 5
CUSEREXIT userexit.dll MyUserExit, & PASSTHRU, &
INCLUDEUPDATEBEFORES, PARAMS 'Some text to start with during startup'
DBOPTIONS

Valid For

Extract and Replicat

Description

Use the DBOPTIONS parameter to specify database options. This is a global parameter, applying to all TABLE or MAP statements in the parameter file.

The TARGETDB or SOURCEDB parameter must precede a DBOPTIONS parameter statement and/or the USERIDALIAS statement. Some DBOPTIONS options apply only to Extract or Replicat.

Default

None

Syntax

DBOPTIONS
[ALLOWLOBDATATRUNCATE | NOALLOWLOBDATATRUNCATE]
[ALLOWUNUSEDCOLUMN | NOALLOWUNUSEDCOLUMN]
[BINDCHARFORBITASCHAR]
[CATALOGCONNECT | NOCATALOGCONNECT]
[CONNECTIONPORT port]
[DECRYPTPASSWORD shared_secret ENCRYPTKEY {DEFAULT | key_name}]
[DEFERREFOCONST]
[DISABLECOMMITNOWAIT]
[DISABLELOBCACHING]
[EMPTYLOBSTRING 'string']
[FETCHBATCHSIZE records]
[FETCHLOBS | NOFETCHLOBS]
[HOST {DNS_name | IP_address}]
[INTEGRATEDPARAMS{parameter[, ...]}]
[LIMITROWS | NOLIMITROWS]
[LOBBUFFSIZE bytes]
[LOBWRITESIZE bytes]
[SESSIONPOOLMAX max_value | SESSIONPOOLMIN min_value]
[SESSIONPOOLINCR increment_value]
[SETTAG [tag_value | NULL] ]
[SHOWINFOMESSAGES]
[SHOWWARNINGS]
[SKIPTEMPLOB | NOSKIPTEMPLOB]
[SPTHREAD | NOSPPTHREAD]
[SUPPRESSTRIGGERS | NOSUPPRESSTRIGGERS]
[TDSPACKETSIZE bytes]
[TRANSNAME trans_name]
[TRUSTEDCONNECTION]
[USEODBC | USEREPPLICATIONUSER]
[XMLBUFFSIZE bytes]

ALLOWUNUSEDCOLUMN | NOALLOWUNUSEDCOLUMN

Valid for Extract for Oracle. Controls whether Extract abends when it encounters a table with an unused column.
The default is `ALLOWUNUSEDCOLUMN`. When Extract encounters a table with an unused column, it continues processing and generates a warning. When using this parameter, either the same unused column must exist on the target or a source definitions file for the table must be specified to Replicat, so that the correct metadata mapping can be performed.

`NOALLOWUNUSEDCOLUMN` causes Extract to abend on unused columns.

**ALLOWLOBDATATRUNCATE | NOALLOWLOBDATATRUNCATE**
Valid for Replicat for DB2 LUW, Sybase, and MySQL. `ALLOWLOBDATATRUNCATE` prevents Replicat from abending when replicated LOB data is too large for a target `CHAR`, `VARCHAR`, `BINARY` or `VARBINARY` column and is applicable to target LOB columns only. `NOALLOWLOBDATATRUNCATE` prevents Replicat from abending when replicated LOB data is too large for a target LOB column. The LOB data is truncated to the maximum size of the target column *without any further error messages or warnings*.

`NOALLOWLOBDATATRUNCATE` is the default and causes Replicat to abend with an error message if the replicated LOB is too large.

**BINDCHARFORBITASCHAR**
Valid for `DEFGEN`, Extract, and Replicat for DB2 for i. Allows columns that are defined as `CHAR` or `VARCHAR` with CCSID 65535, or `CHAR` and `VARCHAR FOR BIT DATA` to be treated as if the field had a normal translatable encoding. The encoding is picked up from the job CCSID. When this option is in effect, `defgen` does not indicate that the field is binary in the `defs` file.

**CATALOGCONNECT | NOCATALOGCONNECT**
Valid for Extract and Replicat for ODBC databases. By default, Oracle GoldenGate creates a new connection for catalog queries, but you can use `NOCATALOGCONNECT` to prevent that. On DB2 for z/OS, `NOCATALOGCONNECT` prevents Oracle GoldenGate from attempting multiple connections when the MVS DB2 initialization parameter `mvsattachtype` is set to `CAF`. Because CAF mode does not support multiple connections, it is possible that Oracle GoldenGate may issue commit locks on the system catalog tablespaces until it receives the commit for its open connection. To prevent commit locks, Oracle GoldenGate recommends using RRSAF (`mvsattachtype=RRSAF`), which supports multiple connections.

**CONNECTIONPORT port**
Valid for Replicat for multi-daemon MySQL. Specifies the TCP/IP port of the instance to which Replicat must connect.

**DECRYPTPASSWORD shared_secret algorithm ENCRYPTKEY (key_name | DEFAULT)**
Valid for Extract in classic capture mode (Oracle)

Specifies the shared secret (password) that decrypts the TDE key, which decrypts redo log data that was encrypted with Oracle Transparent Data Encryption (TDE). The TDE key is first encrypted in the Oracle server by using the shared secret as a key, and then it is delivered to Extract, which decrypts it by using the same shared secret. The shared secret must be created in the Oracle Wallet or Hardware Security Module by the Oracle Server Security Officer. The only other person who should know the shared secret is the Oracle GoldenGate Administrator.

To use the decryption options, you must first generate the encrypted shared secret with the `ENCRYPT PASSWORD` command in GGSCI and create an `ENCKEYS` file.

Parameter options:
**shared_secret**

Is the encrypted shared secret (password) that is copied from the `ENCRYPT PASSWORD` command results.

**algorithm**

Specifies the encryption algorithm that was used to encrypt the password: AES128, AES192, AES256, or BLOWFISH. AES is not supported on DB2 on z/OS, DB2 for i, and SQL/MX.

**ENCRYPTKEY key_name**

Specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if `ENCRYPT PASSWORD` was used with the `KEYNAME key_name` option. Requires an ENCKEYS file to be created on the local system.

**ENCRYPTKEY DEFAULT**

Directs Oracle GoldenGate to use a random key. Use if `ENCRYPT PASSWORD` was used with the `KEYNAME DEFAULT` option.

For more information about configuring Extract to support TDE, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

For more information about Oracle GoldenGate encryption options, including ENCKEYS, see *Administering Oracle GoldenGate for Windows and UNIX*.

**DEFERREFCONST**

Valid for nonintegrated Replicat for Oracle. Sets constraints to DEFERRABLE to delay the checking and enforcement of cascade delete and cascade update referential integrity constraints by the Oracle target database until the Replicat transaction is committed. At that point, if there are constraint violations, an error is generated. Integrated Replicat does not require disabling of referential constraints on the target system.

You can use DEFERREFCONST instead of disabling the constraints on the target tables or setting them to DEFERRED. When used, DEFERREFCONST defers both DEFERABLE and NOT DEFERABLE constraints. DEFERREFCONST applies to every transaction that is processed by Replicat.

If used with an Oracle version that does not support this functionality, DEFERREFCONST is ignored without returning a notification to the Oracle GoldenGate log. To handle errors on the commit operation, you can use `REPERROR` at the root level of the parameter file and specify the TRANSDISCARD or TRANSEXCEPTION option.

**DISABLECOMMITNOWAIT**

Valid for Replicat for Oracle. Disables the use of asynchronous COMMIT by Replicat. An asynchronous COMMIT statement includes the NOWAIT option.

When DISABLECOMMITNOWAIT is used, Replicat issues a standard synchronous COMMIT (COMMIT with WAIT option).

**DISABLELOBCACHING**

Valid for nonintegrated Replicat for Oracle. Disables Oracle’s LOB caching mechanism. By default, Replicat enables Oracle’s LOB caching mechanism.

**EMPTYLOBSTRING 'string'**

Valid for Replicat for Sybase. Substitutes a string value for empty (zero-length) LOB columns, such as Sybase IMAGE or TEXT values, that are replicated to the target. By default, Oracle GoldenGate sets empty columns to NULL on the target and will abend if the target database does not permit LOB columns to be NULL. This option prevents Replicat from abending.
For ‘string’ use any string that the column accepts, and enclose the string within single quotes. The default is NULL.

Example:

DBOPTIONS EMPTYLOBSTRING 'empty'

FETCHBATCHSIZE records
Valid for Extract for Oracle, DB2, SQL/MX, Sybase, SQL Server, Sybase, and Teradata. Enables array fetches for initial loads to improve performance, rather than one row at a time. Valid values are 0 through 1000000 records per fetch. The default is 1000.

Performance slows when batch size gets very small or very large. If the table contains LOB data, Extract reverts to single-row fetch mode, and then resumes batch fetch mode afterward.

HOST (DNS_name | IP_address)
Valid for Replicat for multi-daemon MySQL. Specifies the DNS name or IP address of the system that hosts the instance to which Replicat must connect.

FETCHLOBS | NOFETCHLOBS
Valid for Extract for DB2 for z/OS and DB2 for LUW. Suppresses the fetching of LOBs directly from the database table when the LOB options for the table are set to NOT LOGGED. With NOT LOGGED, the value for the column is not available in the transaction logs and can only be obtained from the table itself. By default, Oracle GoldenGate captures changes to LOBs from the transaction logs. The default is FETCHLOBS.

INTEGRATEDPARAMS parameter[, ...]
Valid for Replicat for Oracle. Passes settings for parameters that control the database inbound server within the target Oracle database. Use this option only for an integrated Replicat. For more information about integrated Replicat and a list of supported inbound server parameters, see Installing and Configuring Oracle GoldenGate for Oracle Database.

LIMITROWS | NOLIMITROWS
Valid for Replicat for MySQL, Oracle, SQL Server, and Sybase. LIMITROWS prevents multiple rows from being updated or deleted by the same Replicat SQL statement when the target table does not have a primary or unique key.

LIMITROWS is the default. LIMITROWS and NOLIMITROWS apply globally to all MAP statements in a parameter file.

For MySQL, LIMITROWS uses a LIMIT 1 clause in the UPDATE or DELETE statement.

For Oracle targets, LIMITROWS (the default) must be used. It uses either WHERE ROWNUM = 1 or AND ROWNUM = 1 in the WHERE clause.

For SQL Server and Sybase, LIMITROWS uses a SET ROWCOUNT 1 clause before the UPDATE or DELETE statement.

NOLIMITROWS permits multiple rows to be updated or deleted by the same Replicat SQL statement.

LOBBUFSIZE bytes
Valid for Extract for Oracle. Determines the memory buffer size in bytes to allocate for each embedded LOB attribute that is in an Oracle object type. Valid values are from 1024 and 10485760 bytes. The default is 1048576 bytes.

If the length of embedded LOB exceeds the specified LOBBUFSIZE size, an error message similar to the following is generated:

GGS ERROR ZZ-0L3 Buffer overflow, needed: 2048, allocated: 1024.
**LOBWRITESIZE bytes**
Valid for nonintegrated Replicat for Oracle. Specifies a fragment size in bytes for each LOB that Replicat writes to the target database. The LOB data is stored in a buffer until this size is reached. Because LOBs must be written to the database in fragments, writing in larger blocks prevents excessive I/O. The higher the value, the fewer I/O calls that are made by Replicat to the database server to write the whole LOB to the database.

Specify a multiple of the Oracle LOB fragment size. A given value will be rounded up to a multiple of the Oracle LOB fragment size, if necessary. The default LOB write size is 32k if DBOPTIONS NOSKIPTEMPLOB is specified, or 1MB if DBOPTIONS SKIPTEMPLOB is specified. Valid values are from 2,048 bytes to 2,097,152 bytes (2MB).

By default, Replicat enables Oracle's LOB caching mechanism. To disable Oracle's LOB caching, use the DISABLELOBCACHING option of DBOPTIONS.

**SHOWINFOMESSAGES**
Valid for Extract and Replicat for Sybase. Enables the following Sybase server messages to be printed to the error log.

- 0: /* General informational message */
- 5701: /* Changed Database Context */
- 5703: /* Changed language setting */
- 5704: /* Changed client character set */
- 7326: /* Non ANSI Escaping */

Normally, these messages are suppressed because they do not affect Oracle GoldenGate processing.

**SHOWWARNINGS**
Valid for Extract and Replicat for Sybase. Enables the logging of Sybase server messages with a severity level greater than 10. These messages may be useful for debugging when Sybase performs corrective action that causes data to change.

**SESSIONPOOLMAX max_value**
Valid for Extract in integrated mode for Oracle. Sets a maximum value for the number of sessions in the OCI Session Pool, which is used by Extract for fetching from a container database. The default value is 10 sessions. Must be specified before the USERID or USERIDALIAS parameter; otherwise will be ignored and the default will be used.

**SESSIONPOOLMIN min_value**
Valid for Extract in integrated mode for Oracle. Sets a minimum value for the number of sessions in the OCI Session Pool, which is used by Extract for fetching from a container database. The default value is 2 sessions. Must be specified before the USERID or USERIDALIAS parameter; otherwise will be ignored and the default will be used.

**SESSIONPOOLINCR increment_value**
Valid for Extract in integrated mode for Oracle. Sets a value for the number of incremental sessions that can be added to the OCI Session Pool, which is used by Extract for fetching from a container database. The default value is 2 sessions. Must be specified before the USERID or USERIDALIAS parameter; otherwise will be ignored and the default will be used.

**SETTAG [tag_value | NULL**
Valid for Replicat for Oracle. Sets the value for an Oracle redo tag that will be used to identify the transactions of the associated Replicat in the redo log. A redo tag also can be used to identify transactions other than those of Replicat.
Use this option to prevent cycling (loop-back) of Replicat the individual records in a bi-directional configuration or to filter other transactions from capture. The default SETTAG value is 00. Valid value is any single Oracle Streams tag. A tag value can be up to 2000 hexadecimal digits (0-9 A-F) long. For more information about Streams tags, see Oracle Streams Replication Administrator’s Guide.

Transactions in the redo that are marked with the specified tag can be filtered by an Extract that has the TRANLOGOPTIONS parameter with the EXCLUDETAG option set to the tag_value. Use tag-based filtering to prevent cycling (loop-back) of Replicat transactions in a bi-directional configuration or to filter other transactions from capture. For more information, see TRANLOGOPTIONS.

You can disable the tagging of DDL by using the DDLOPTIONS parameter with the NOTAG option.

**hex_value**
A hexadecimal value from 0 through F. The default value is 00. The following are valid examples:

```
DBOPTIONS SETTAG 00112233445566778899AABBCCDDEEFF
DBOPTIONS SETTAG 00112233445566778899aabbccddeeff
DBOPTIONS SETTAG 123
```

**NULL**
Disables tag-based filtering for the associated Replicat.

**SKIPTEMPLOB | NOSKIPTEMPLOB**
Valid for Replicat for Oracle database versions 11g and 12c. Controls how LOBs are applied to a target Oracle database. The default of SKIPTEMPLOB improves performance by directly writing LOB data to the target LOB column. Replicat creates a SQL statement with an empty LOB value and returns the LOB locator to the bind variable. After the SQL statement is executed successfully, the LOB data is written directly to the LOB column using the returned LOB locator.

NOSKIPTEMPLOB uses a temporary LOB in the SQL statement. Replicat declares a bind variable within SQL statement and associates a temporary LOB, then writes to the temporary LOB. The Oracle database applies the LOB column data from the temporary LOB.

SKIPTEMPLOB applies to INSERT and UPDATE operations that contain LOB data. It does not apply if the table has a functional index with a LOB column, if the LOB data is NULL, empty, or stored inline. It also does not apply to partial LOB operations.

Oracle GoldenGate allocates a minimum 1MB LOB-write chunk size when SKIPTEMPLOB is enabled, and a warning message is issued if a value of less than 1MB is specified for the LOBWRITESIZE option of DBOPTIONS. The LOB write chunk size for each column is adjusted and rounded by the database, and the actual LOB write chunk size may differ from the value of LOBWRITESIZE depending on the LOB storage attribute of the target table and the LOB type.

NOSKIPTEMPLOB is provided for backward compatibility; otherwise the default of SKIPTEMPLOB should be retained.

**SPTHREAD | NOSPTHREAD**
Valid for Extract and Replicat. Creates a separate database connection thread for stored procedures. The default is NOSPTHREAD.
**SUPPRESSTRIGGERS | NOSUPPRESSTRIGGERS**

Valid for nonintegrated Replicat for Oracle. Controls whether or not triggers are fired during the Replicat session. Provides an alternative to manually disabling triggers. (Integrated Replicat does not require disabling of triggers on the target system.)

**SUPPRESSTRIGGERS** is the default and prevents triggers from firing on target objects that are configured for replication with Oracle GoldenGate. **SUPPRESSTRIGGERS** is valid for Oracle 11.2.0.2 and later 11gR2 versions. **SUPPRESSTRIGGERS** is not valid for 11gR1.

To allow a specific trigger to fire, you can use the following `SQLEXEC` statement in the Replicat parameter file, where `trigger_owner` is the owner of the trigger and `trigger_name` is the name of the trigger.

```
SQLEXEC 'dbms_ddl.set_trigger_firing_property(trigger_owner "trigger_name", FALSE);
```

**Note:** Once this `SQLEXEC` is executed with `FALSE`, the trigger will continue to fire until the command is run again with a setting of `TRUE`.

**NOSUPPRESSTRIGGERS** allows target triggers to fire. To use `[NO]SUPPRESSTRIGGERS`, the Replicat user must have the privileges granted through the `dbms_goldengate_auth.grant_admin_privilege` package. This procedure is part of the Oracle database installation. See the database documentation for more information.

The `USERID` or `USERIDALIAS` parameter must precede a `DBOPTIONS` statement that contains `SUPPRESSTRIGGERS` or `NOSUPPRESSTRIGGERS`.

**TDSPACKETSIZE bytes**

Valid for Extract and Replicat for Sybase. Sets the TDS packet size for replication to a Sybase target.

Valid values:

- Sybase version 12.5.4:

  **Note:** This version is de-supported as of Oracle GoldenGate 11.2.1.

  512 to 65024

  Default is 0 for Extract, 512 for Replicat

- Sybase15 or higher:

  2048 to 65024

  Default is 0 for Extract, 2048 for Replicat

The value must be a multiple of 512. The range of values that are set for the Sybase Adaptive Server `max network packet size` and `additional network memory` parameters must support the value that is set with `TDSPACKETSIZE`.

**Note:** The higher the `max network packet size` value, the more memory (as set with `additional network memory`) the database server needs to allocate for the network data.
For best performance, choose a server packet size that works efficiently with the underlying packet size on your network. The goals of this procedure are to:

- Reduce the number of server reads and writes to the network.
- Reduce unused space in the network packets to increase network throughput.

For example, if your network packet size carries 1500 bytes of data, you can achieve better transfer performance by setting the packet size on the server to 1024 (512 x 2) than by setting it to 1536 (512 x 3).

For optimal performance, start with the following configuration:

```
DBOPTIONS TDSPACKETSIZE 8192
```

The `DBOPTIONS` parameter that contains `TDSPACKETSIZE` must be placed before the `SOURCEDB` or `TARGETDB` parameter in the parameter file.

**TRANSNAME trans_name**
Valid for Replicat for SQL Server. Allows an individual Replicat to use a specific transaction name that is specified in the parameter file.

**TRUSTEDCONNECTION**
Valid for Extract and Replicat for SQL Server. Causes Oracle GoldenGate to connect by using `trusted connection = yes`. Contact Oracle Support before using this option.

**USEODBC**
Valid for Replicat for SQL Server. Configures Replicat to use ODBC to perform DML operations. The default is to use OLE DB. Not valid if `USEREPPLICATIONUSER` is enabled; will cause Replicat to abend.

---

**Note:** Replicat always uses ODBC to connect to the database catalog to obtain metadata.

---

**USEREPPLICATIONUSER**
Valid for Replicat for SQL Server. Configures Replicat to perform target DML operations as the SQL Server replication user. The replication user is not a SQL Server user or account, but is a property of the database connection. `USEREPPLICATIONUSER` enables the SQL Server `NOT FOR REPLICATION` flag.

When the replication user is used, the following concerns must be addressed for their effect on data integrity:

- **IDENTITY** seeds on the target are not updated. A partitioning scheme is needed to avoid primary key violations unless the target is read-only.
- Foreign key constraints are not enforced.
- **ON UPDATE CASCADE, ON DELETE CASCADE** and triggers are disabled. This is beneficial to Replicat, since it prevents duplicate operations, but may not be appropriate for the target applications and might require modification to the code of the constraint or trigger to ensure data integrity.
- **CHECK** constraints are not enforced, so data integrity cannot be certain on the target.

When using `USEREPPLICATIONUSER`, **IDENTITY** properties and constraints must be set with the 'not for replication' option at the object level within the database. For
more information about these considerations, see *Installing and Configuring Oracle GoldenGate for SQL Server*.

By default, USEREPlicationUSER is disabled and the default is to use OLE DB. The use of USEREPlicationUSER is only advised if delivery performance must be increased. Not valid if USEODBC is enabled; will cause Replicat to abend.

**XMLBUFSIZE bytes**

Valid for Extract for Oracle. Sets the size of the memory buffer that stores XML data that was extracted from the `sys.xmltype` attribute of a SDO_GEORASTER object type. The default is 1048576 bytes (1MB). If the data exceeds the default buffer size, Extract will abend. If this occurs, increase the buffer size and start Extract again. The valid range of values is 1024 to 10485760 bytes.

**Examples**

**Example 1**

```
DBOPTIONS HOST 127.0.0.1, CONNECTIONPORT 3307
```

**Example 2**

```
DBOPTIONS DECRYPTPASSWORD AACCAAAAAAAAIAALCKDZIBH0JH0JUH ENCRYPTKEY DEFAULT
```

**Example 3**

```
DBOPTIONS TSQPACKETSIZE 2048
```

**Example 4**

```
DBOPTIONS FETCHBATCHSIZE 2000
```

**Example 5**

```
DBOPTION XMLBUFSIZE 2097152
```
DDL

Valid For

Extract and Replicat

Description

Use the DDL parameter to:

■ enable DDL support
■ filter DDL operations
■ configure a processing action based on a DDL record

When used without options, the DDL parameter performs no filtering, and it causes all DDL operations to be propagated as follows:

■ As an Extract parameter, it captures all supported DDL operations that are generated on all supported database objects and sends them to the trail.

■ As a Replicat parameter, it replicates all DDL operations from the Oracle GoldenGate trail and applies them to the target. This is the same as the default behavior without this parameter.

When used with options, the DDL parameter acts as a filtering agent to include or exclude DDL operations based on:

■ scope
■ object type
■ operation type
■ object name
■ strings in the DDL command syntax or comments, or both

Only one DDL parameter can be used in a parameter file, but you can combine multiple inclusion and exclusion options to filter the DDL to the required level.

■ The filtering options of the DDL parameter are valid for a primary Extract that captures from the transaction source, but not for a data-pump Extract.

■ When combined, multiple filter option specifications are linked logically as AND statements.

■ All filter criteria specified with multiple options must be satisfied for a DDL statement to be replicated.

■ When using complex filtering criteria in a DDL parameter statement, it is recommended that you test your configuration in a test environment before using it in production.

■ See Example 1 for more information.

Do not use the DDL parameter for:

■ an Extract data pump
■ a VAM-sort Extract (Teradata source databases)

These process types do not permit the mapping or conversion of DDL and will propagate DDL records automatically in pass-through mode. DDL that is performed
on a source table (for example ALTER TABLE TableA...) will be applied by Replicat with the same table name (ALTER TABLE TableA). It cannot be mapped as ALTER TABLE TableB. See "PASSTHRU | NOPASSTHRU" on page 3-209 for more information about pass-through mode.

For additional information about how to use Oracle GoldenGate DDL support, see *Installing and Configuring Oracle GoldenGate for Oracle Database or Installing and Configuring Oracle GoldenGate for Teradata*, as applicable.

**Syntax**

```plaintext
DDL [ {INCLUDE | EXCLUDE]
    [, MAPPED | UNMAPPED | OTHER | ALL]
    [, OPTYPE type]
    [, OBJTYPE 'type']
    [, SOURCECATALOG catalog | ALLCATALOGS]
    [, ALLOWEMPTYPETABLE]
    [, ALLOWEMPTOWNER]
    [, OBJNAME name]
    [, INSTR 'string']
    [, INSTRWORDS 'word_list']
    [, INSTRCOMMENTS 'comment_string']
    [, INSTRCOMMENTSWORDS 'word_list']
    [, STAYMETADATA]
    [, EVENTACTIONS (action)]
}
[...]
```

**DDL Filtering Options**

The following are the syntax options for filtering and operating upon the DDL that is replicated by Oracle GoldenGate. These options apply to the INCLUDE and EXCLUDE clauses of the DDL parameter and other parameters that support DDL replication.

**INCLUDE | EXCLUDE**

Use INCLUDE or EXCLUDE to identify the beginning of an inclusion or exclusion clause.

- An inclusion clause contains filtering criteria that identifies the DDL that this parameter will affect.
- An exclusion clause contains filtering criteria that excludes specific DDL from this parameter.

The inclusion or exclusion clause must consist of the INCLUDE or EXCLUDE keyword followed by any valid combination of the other filtering options of the DDL parameter.

If you use EXCLUDE, you must create a corresponding INCLUDE clause. For example, the following is invalid:

```plaintext
DDL EXCLUDE OBJNAME hr.*
```

However, you can use either of the following:

- `DDL INCLUDE ALL, EXCLUDE OBJNAME hr.*`
- `DDL INCLUDE OBJNAME fin.* EXCLUDE OBJNAME fin.ss`

An EXCLUDE takes priority over any INCLUDEs that contain the same criteria. You can use multiple inclusion and exclusion clauses.

Do not include any Oracle GoldenGate installed DDL objects in a DDL parameter, in a TABLE parameter, or in a MAP parameter, nor in a TABLEEXCLUDE or MAPEXCLUDE...
parameter. Make certain that wildcard specifications in those parameters do not include Oracle GoldenGate-installed DDL objects. These objects must not be part of the Oracle GoldenGate configuration, but the Extract process must be aware of operations on them, and that is why you must not explicitly exclude them from the configuration with an EXCLUDE, TABLEEXCLUDE, or MAPEXCLUDE parameter statement.

**MAPPED | UNMAPPED | OTHER | ALL**

Use MAPPED, UNMAPPED, OTHER, and ALL to apply INCLUDE or EXCLUDE based on the DDL operation scope.

- **MAPPED** applies INCLUDE or EXCLUDE to DDL operations that are of MAPPED scope. MAPPED filtering is performed before filtering that is specified with other DDL parameter options.
- **UNMAPPED** applies INCLUDE or EXCLUDE to DDL operations that are of UNMAPPED scope.
- **OTHER** applies INCLUDE or EXCLUDE to DDL operations that are of OTHER scope.
- **ALL** applies INCLUDE or EXCLUDE to DDL operations of all scopes.

**DDL EXCLUDE ALL** is a special processing option that maintains up-to-date object metadata for Oracle GoldenGate, while blocking the replication of the DDL operations themselves. You can use DDL EXCLUDE ALL when using a method other than Oracle GoldenGate to apply DDL to the target, but you want Oracle GoldenGate to replicate data changes to the target objects. It provides the current metadata to Oracle GoldenGate as objects change, thus preventing the need to stop and start the Oracle GoldenGate processes. The following special conditions apply to DDL EXCLUDE ALL:

- **DDL EXCLUDE ALL** does not require the use of an INCLUDE clause.
- When using DDL EXCLUDE ALL, you can set the WILDCARDRESOLVE parameter to IMMEDIATE to allow immediate DML resolution if required.

**OPTYPE type**

Use OPTYPE to apply INCLUDE or EXCLUDE to a specific type of DDL operation, such as CREATE, ALTER, and RENAME. For type, use any DDL command that is valid for the database. For example, to include ALTER operations, the correct syntax is:

```
DDL INCLUDE OPTYPE ALTER
```

**OBJTYPE 'type'**

Use OBJTYPE to apply INCLUDE or EXCLUDE to a specific type of database object. For type, use any object type that is valid for the database, such as TABLE, INDEX, and TRIGGER. For an Oracle materialized view and materialized views log, the correct types are snapshot and snapshot log, respectively. Enclose the name of the object type within single quotes. For example:

```
DDL INCLUDE OBJTYPE 'INDEX'
DDL INCLUDE OBJTYPE 'SNAPSHOT'
```

For Oracle object type USER, do not use the OBJNAME option, because OBJNAME expects owner.object or container.owner.object whereas USER only has a schema.

**SOURCECATALOG catalog | ALLCATALOGS**

Use these options to specify how unqualified object names in an OBJNAME clause are resolved to the correct container. Use these options when the source database is an Oracle container database.
**SOURCECATALOG** specifies a default container for all of the object names that are specified in the same *INCLUDE* or *EXCLUDE* clause. To take effect, **SOURCECATALOG** must be specified before the *OBJNAME* specification. See "**SOURCECATALOG**" on page 3-275 for more information including using statements that contain two-part names, where three-part object names are required to fully identify an object.

**ALLCATALOGS** specifies that all of the containers of the database should be considered when resolving object names that are specified in the same *INCLUDE* or *EXCLUDE* clause. **ALLCATALOGS** can be placed before or after the *OBJNAME* specification.

The following is the order of precedence that is given when there are different catalog specifications in a parameter file:

1. **ALLCATALOGS** in an *INCLUDE* or *EXCLUDE* clause overrides all **SOURCECATALOG** specifications in the *INCLUDE* or *EXCLUDE* clause and at the root of the parameter file, and it overrides the container specification of a fully qualified object name in the *OBJNAME* clause.

2. An explicit catalog specification in the *OBJNAME* clause overrides all instances of **SOURCECATALOG** (but not **ALLCATALOGS**).

3. **SOURCECATALOG** in an *INCLUDE* or *EXCLUDE* clause overrides the global **SOURCECATALOG** parameter that is specified at the root of the *TABLE* or *MAP* statement.

4. The global **SOURCECATALOG** parameter takes effect for any unqualified object names in *OBJNAME* clauses if the *INCLUDE* or *EXCLUDE* clause does not specify **SOURCECATALOG** or **ALLCATALOGS**.

5. In the absence of any of the preceding parameters, all catalogs are considered.

**ALLOWEMPTYOBJECT**
Use **ALLOWEMPTYOBJECT** to allow an *OBJNAME* specification to process DDL that contains no object name. For example:

```
DDL INCLUDE OBJNAME sch.* ALLOWEMPTYOBJECT
```

**ALLOWEMPTYOWNER**
Use **ALLOWEMPTYOWNER** to allow an *OBJNAME* specification to process DDL that contains no owner name. For example:

```
DDL INCLUDE OBJNAME pdb.sch.* ALLOWEMPTYOWNER
```

**OBJNAME** name
Use **OBJNAME** to apply *INCLUDE* or *EXCLUDE* to the fully qualified name of an object. To specify two-part and three-part object names and wildcards correctly, see *Administering Oracle GoldenGate for Windows and UNIX*.

Enclose case-sensitive object names within double quote marks.

Case-insensitive example:

```
DDL INCLUDE OBJNAME accounts.*
```

Case-sensitive example:

```
DDL INCLUDE OBJNAME accounts."cust"
```

Do not use **OBJNAME** for the Oracle USER object, because **OBJNAME** expects *owner.object* or *container.owner.object*, whereas USER only has a schema.
When using `OBJNAME` with `MAPPED` in a Replicat parameter file, the value for `OBJNAME` must refer to the name specified with the `TARGET` clause of the `MAP` statement. For example, given the following `MAP` statement, the correct value is `OBJNAME fin2.*`.

```
MAP fin.exp_*, TARGET fin2.*;
```

In the following example, a `CREATE TABLE` statement executes as follows on the source:

```
CREATE TABLE fin.exp_phone;
```

That same statement executes as follows on the target:

```
CREATE TABLE fin2.exp_phone;
```

If a target owner is not specified in the `MAP` statement, Replicat maps it to the database user that is specified with the `USERID` or `USERIDALIAS` parameter.

For DDL that creates derived objects, such as a trigger, the value for `OBJNAME` must be the name of the base object, not the name of the derived object.

For example, to include the following DDL statement, the correct value is `hr.accounts, not hr.insert_trig`.

```
CREATE TRIGGER hr.insert_trig ON hr.accounts;
```

For `RENAME` operations, the value for `OBJNAME` must be the new table name. For example, to include the following DDL statement, the correct value is `hr.acct`.

```
ALTER TABLE hr.accounts RENAME TO acct;
```

**INSTR 'string'**

Use `INSTR` to apply `INCLUDE` or `EXCLUDE` to DDL statements that contain a specific character string within the command syntax itself, but not within comments. For example, the following excludes DDL that creates an index.

```
DDL INCLUDE ALL EXCLUDE INSTR 'CREATE INDEX'
```

Enclose the string within single quotes. The string search is not case sensitive.

`INSTR` does not support single quotation marks (') that are within the string, nor does it support `NULL` values.

**INSTRCOMMENTS 'comment_string'**

(Valid for Oracle) Use `INSTRCOMMENTS` to apply `INCLUDE` or `EXCLUDE` to DDL statements that contain a specific character string within a comment, but not within the DDL command itself. By using `INSTRCOMMENTS`, you can use comments as a filtering agent.

For example, the following excludes DDL statements that include the string ‘source only’ in the comments.

```
DDL INCLUDE ALL EXCLUDE INSTRCOMMENTS 'SOURCE ONLY'
```

In this example, DDL statements such as the following are not replicated.

```
CREATE USER john IDENTIFIED BY john /*source only*/;
```

Enclose the string within single quotes. The string search is not case sensitive. You can combine `INSTR` and `INSTRCOMMENTS` to filter on a string in the command syntax and in the comments of the same DDL statement.
INSTRCOMMENTS does not support single quotation marks (’’) that are within the string, nor does it support NULL values.

INSTRWORDS ‘word_list’
Use INSTRWORDS to apply INCLUDE or EXCLUDE to DDL statements that contain the specified words.

For word_list, supply the words in any order, within single quotes. To include spaces, put the space (and the word, if applicable) in double quotes. Double quotes also can be used to enclose sentences.

All specified words must be present in the DDL for INSTRWORDS to take effect.

Example:

```
DDL INCLUDE OPTYPE ALTER OBJTEYP 'TABLE' INSTRWORDS 'ALTER CONSTRAINT "xyz"
```

This example matches the following DDL statements:

```
ALTER TABLE ADD CONSTRAINT xyz CHECK
ALTER TABLE DROP CONSTRAINT xyz
```

INSTRWORDS does not support single quotation marks (’’) that are within the string, nor does it support NULL values.

INSTRCOMMENTSWORDS ‘word_list’
(Valid for Oracle) Works the same way as INSTRWORDS, but only applies to comments within a DDL statement, not the DDL syntax itself. By using INSTRCOMMENTS, you can use comments as a filtering agent.

INSTRCOMMENTSWORDS does not support single quotation marks (’’) that are within the string, nor does it support NULL values.

You can combine INSTRWORDS and INSTRCOMMENTSWORDS to filter on a string in the command syntax and in the comments of the same DDL statement.

STAYMETADATA
(Valid for Oracle). Prevents metadata from being captured by Extract or applied by Replicat.

When Extract first encounters DML on a table, it retrieves the metadata for that table. When DDL is encountered on that table, the old metadata is invalidated. The next DML on that table is matched to the new metadata so that the target table structure always is up-to-date with that of the source.

However, if you know that a particular DDL operation will not affect the table’s metadata, you can use STAYMETADATA so that the current metadata is not retrieved or replicated. This is a performance improvement that has benefit for such operations as imports and exports, where such DDL as truncates and the disabling of constraints are often performed. These operations do not affect table structure, as it relates to the integrity of subsequent data replication, so they can be ignored in such cases. For example ALTER TABLE ADD FOREIGN KEY does not affect table metadata.

An example of how this can be applied selectively is as follows:

```
DDL INCLUDE ALL INCLUDE STAYMETADATA OBJNAME xyz
```

This example states that all DDL is to be included for replication, but only DDL that operates on object xyz will be subject to STAYMETADATA.
STAYMETADATA also can be used the same way in an EXCLUDE clause.

STAYMETADATA must be used the same way on the source and target to ensure metadata integrity.

When STAYMETADATA is in use, a message is added to the report file. DDL reporting is controlled by the DDLOPT options parameter with the REPORT option.

This same functionality can be applied globally to all DDL that occurs on the source by using the @ddl_staymetadatad scripts:

- @ddl_staymetadata_on globally turns off metadata versioning.
- @ddl_staymetadata_off globally enables metadata versioning again.

This option should be used with the assistance of Oracle GoldenGate technical support staff, because it might not always be apparent which DDL affects object metadata. If improperly used, it can compromise the integrity of the replication environment.

EVENTACTIONS (action)
Causes the Extract or Replicat process take a defined action based on a DDL record in the transaction log or trail, which is known as the event record. The DDL event is triggered if the DDL record is eligible to be written to the trail by Extract or a data pump, or to be executed by Replicat, as determined by the other filtering options of the DDL parameter. You can use this system to customize processing based on database events.

For action, see EVENTACTIONS under the MAP and TABLE parameters.

Guidelines for using EVENTACTIONS on DDL records:

- CHECKPOINTBEFORE: Since each DDL record is autonomous, the DDL record is guaranteed to be the start of a transaction; therefore, the CHECKPOINT BEFORE event action is implied for a DDL record.
- IGNORE: This option is not valid for DDL records. Because DDL operations are autonomous, ignoring a record is equivalent to ignoring the entire transaction.

EVENTACTIONS does not support the following DDL objects because they are derived objects:

- indexes
- triggers
- synonyms
- RENAME on a table and ALTER TABLE RENAME

In a Teradata configuration where Extract is configured in maximum protection mode, use EVENTACTIONS only in the VAM-sort Extract group. It is not supported by the primary Extract in this configuration because concurrent changes are not sorted in transaction order at this point in the processing stream. For more information, see Installing and Configuring Oracle GoldenGate for Teradata.

Examples

Example 1 Combining DDL Parameter Options
The following is an example of how to combine the options of the DDL parameter.

```sql
DDL &
INCLUDE UNMAPPED &
```
The combined filter criteria in this statement specify the following:

- INCLUDE all ALTER TABLE statements for tables that are not mapped with a TABLE or MAP statement (UNMAPPED scope), but only if those tables are owned by users and their names start with tab,
- INCLUDE all DDL operation types for all tables that are mapped with a TABLE or MAP statement (MAPPED scope),
- EXCLUDE all DDL operation types for all tables that are MAPPED in scope, but only if those tables are owned by temporary and only if their names begin with tab.

**Example 2 Including an Event Action**
The following example specifies an event action of REPORT for all DDL records.

```
DDL INCLUDE ALL EVENTACTIONS (REPORT)
```

**Example 3 Using an Event Action on a Subset of DDL**
The following example shows how EVENTACTIONS can be used on a subset of the DDL. All DDL is to be replicated, but only the DDL that is executed on explicitly named objects qualifies to trigger the event actions of REPORT and LOG.

```
DDL INCLUDE ALL &
  INCLUDE OBJNAME sales.t* EVENTACTIONS (REPORT) &
  INCLUDE OBJNAME fin.my_tab EVENTACTIONS (LOG) &
```

**Example 4**
The following example demonstrates the different ways to specify catalog names for DDL that is issued on objects in a source Oracle container database.

- This includes pdb1.sch1.obj1 and pdb2.sch2.obj2 for DDL processing.

```
SOURCECATALOG pdb1
DDL INCLUDE OBJNAME sch1.obj1 INCLUDE SOURCECATALOG pdb2 OBJNAME sch2.obj2
```

- This includes all objects with the name sch.obj in any catalog for DDL processing.

```
DDL INCLUDE ALLCATALOGS OBJNAME sch.obj
```

- This also includes all objects with the name sch.obj in any catalog for DDL processing, because ALLCATALOGS overrides any other catalog specification.

```
DDL INCLUDE ALLCATALOGS OBJNAME pdb.sch.obj
```

**Example 5**
The following shows the combined use of ALLOWEMPTYOBJECT and ALLOWEMPTYOWNER.

```
DDL INCLUDE pdb.*.* ALLOWEMPTYOWNER ALLOWEMPTYOBJECT
```
DDLERROR

Valid For
Extract and Replicat

Description
Use the DDLERROR parameter to handle DDL errors on the source and target systems. Options are available for Extract and Replicat.

DDLERROR for Extract
Use the Extract option of the DDLERROR parameter to handle errors on objects found by Extract for which metadata cannot be found.

Default
Abend

Syntax
DDLERROR [RESTARTSKIP number_of_skips] [RETRYDELAY seconds] [SKIPTRIGGERERROR number_of_errors]

RESTARTSKIP number_of_skips
Causes Extract to skip and ignore a specific number of DDL operations on startup, to prevent Extract from abending on an error. By default, a DDL error causes Extract to abend so that no operations are skipped. Valid values are 1 to 100000.

To write information about skipped operations to the Extract report file, use the DDLOPTIONS parameter with the REPORT option.

RETRYDELAY
Specifies the delay between attempts to retry a failed operation. The default is 60 seconds.

SKIPTRIGGERERROR number_of_errors
(Oracle) Causes Extract to skip and ignore a specific number of DDL errors that are caused by the DDL trigger on startup. Valid values are 1 through 100000.

SKIPTRIGGERERROR is checked before the RESTARTSKIP option. If Extract skips a DDL operation because of a trigger error, that operation is not counted toward the RESTARTSKIP specification.

DDLERROR for Replicat
Use the Replicat options of the DDLERROR parameter to handle errors that occur when DDL is applied to the target database. With DDLERROR options, you can handle most errors in a default manner, for example to stop processing, and also handle other errors in a specific manner. You can use multiple instances of DDLERROR in the same parameter file to handle all errors that are anticipated.

Default
Abend
### Syntax

```plaintext
DDLERROR
{error | DEFAULT} {response}
{INCLUDE inclusion_clause | EXCLUDE exclusion_clause}
[IGNOREMISSINGOBJECTS | ABENDONMISSINGOBJECTS]
[RETRYDELAY seconds]

{error | DEFAULT} {response}
```

**error**
Specifies an explicit DDL error for this `DDLERROR` statement to handle.

**DEFAULT**
Specifies a default `response` to any DDL errors for which there is not an explicit `DDLERROR` statement.

**response**
The action taken by Replicat when a DDL error occurs. Can be one of the following:

- **ABEND**
  Roll back the operation and terminate processing abnormally. ABEND is the default.

- **DISCARD**
  Log the offending operation to the discard file but continue processing subsequent DDL.

- **IGNORE**
  Ignore the error.

**{INCLUDE inclusion_clause | EXCLUDE exclusion_clause}**
Identifies the beginning of an inclusion or exclusion clause that controls whether specific DDL is handled or not handled by the `DDLERROR` statement. See "DDL Filtering Options" on page 3-78 for syntax and usage.

**{IGNOREMISSINGOBJECTS | ABENDONMISSINGOBJECTS}**
Controls whether or not Extract abends when DML is issued on objects that could not be found on the target. This condition typically occurs when DDL that is not in the replication configuration is issued directly on the target, or it can occur when there is a discrepancy between the source and target definitions.

- **IGNOREMISSINGOBJECTS**
  Causes Replicat to skip DML operations on missing tables.

- **ABENDONMISSINGOBJECTS**
  Causes Replicat to abend on DML operations on missing tables.

**{RETRYDELAY seconds}**
Specifies the delay in seconds between attempts to retry a failed operation. The default is 60 seconds.

### Examples

**Example 1 DDLERROR Basic Example**
In the following example, the `DDLERROR` statement causes Replicat to ignore the specified error, but not before trying the operation again three times at ten-second
intervals. Replicat applies the error handling to DDL operations executed on objects whose names satisfy the wildcard of `tab*` (any user, any operation) except those that satisfy `tab1*`.

```
DDLERROR 1234 IGNORE RETRYOP MAXRETRIES 3 RETRYDELAY 10 &
INCLUDE ALL OBJTYPE TABLE OBJNAME tab* EXCLUDE OBJNAME tab1*
```

To handle all errors except that error, the following DDLERROR statement can be added.

```
DDLERROR DEFAULT ABEND
```

In this case, Replicat abends on DDL errors.

**Example 2 Using Multiple DDLERROR Statements**

The order in which you list DDLERROR statements in the parameter file does not affect their validity unless multiple DDLERROR statements specify the same error, without any additional qualifiers. In that case, Replicat only uses the first one listed. For example, given the following statements, Replicat will abend on the error.

```
DDLERROR 1234 ABEND
DDLERROR 5678 IGNORE
```

With the proper qualifiers, however, the previous configuration becomes a more useful one. For example:

```
DDLERROR 1234 ABEND INCLUDE OBJNAME tab*
DDLERROR 5678 IGNORE
```

In this case, because there is an INCLUDE statement, Replicat will abend only if an object name in an errant DDL statement matches wildcard `tab*`. Replicat will ignore errant operations that include any other object name.
DDLOPTONS

Valid For

Extract and Replicat

Description

Use the DDLOPTONS parameter to configure aspects of DDL processing other than filtering and string substitution. You can use multiple DDLOPTONS statements, but using one is recommended. If using multiple DDLOPTONS statements, make each of them unique so that one does not override the other. Multiple DDLOPTONS statements are executed in the order listed in the parameter file.

For more information about how to use DDLOPTONS within the context of Oracle GoldenGate DDL support, see the Installing and Configuring Oracle GoldenGate for Oracle Database or Installing and Configuring Oracle GoldenGate for Teradata as appropriate for your installation.

Default

See the argument descriptions

Syntax

DDLOPTONS
[, ADDTRANDATA {ABEND | RETRYOP RETRYDELAY seconds MAXRETRIES retries}
[, DEFAULTUSERPASSWORD password [ENCRYPTKEY DEFAULT | ENCRYPTKEY key_name] ]
[, CAPTUREGLOBALTEMPTABLE ]
[, DEFAULTUSERPASSWORDALIAS alias [DOMAIN domain] ]
[, GETAPPLOPS | IGNOREAPPLOPS]
[, GETREPLICATES | IGNOREREPLICATES]
[, IGNOREMAPPING]
[, MAPDERIVED | NOMAPDERIVED]
[, MAPSCHEMAS]
[, MAPSESSIONSCHEMA source_schema TARGET target_schema]
[, NOTAG]
[, PASSWORD ENCRYPTKEY [DEFAULT | ENCRYPTKEY key_name]
[, REMOVECOMMENTS (BEFORE | AFTER)]
[, REPLICATEPASSWORD | NOREPLICATEPASSWORD]
[, REPORT | NOREPORT]
[, UPDATEMETADATA]
[, USEPASSWORDVERIFIERLEVEL (10|11)]
[, USEOWNERFORSESSION]

ADDTRANDATA (ABEND | RETRYOP RETRYDELAY seconds MAXRETRIES retries)
Valid for Extract (Teradata)

Not supported when Classic Extract is reading from an Active Data Guard standby database because supplemental logging must be enabled on the primary database, which is read/write. Not supported for multitenant container databases. Supplemental logging must be enabled when using ADD SCHEMATRANDATA. This option should only be used when schema-level supplemental logging is not an option in your environment.

No longer valid for Oracle and a warning is issued if used.

Use ADDTRANDATA to:
Enable Oracle supplemental logging automatically for new tables created with a `CREATE TABLE` statement.

- Update supplemental logging for tables affected by an `ALTER TABLE` statement to add or drop columns.
- Update supplemental logging for tables that are renamed.
- Update supplemental logging for tables where unique or primary keys are added or dropped.

By default, `ADDTRANDATA` is disabled. The default for `ADDTRANDATA` when used without additional options is:

```
DDLOPTONS ADDTRANDATA RETRYOP RETRYDELAY 10 MAXRETRIES 10
```

To use `ADDTRANDATA` functionality, Oracle GoldenGate, the database, and the appropriate tables must be configured for DDL capture. For Oracle, the Oracle GoldenGate DDL objects must be installed and configured. For more information, see `Installing and Configuring Oracle GoldenGate for Oracle Database` or the `Installing and Configuring Oracle GoldenGate for Teradata`, depending on your environment.

For new tables created with `CREATE TABLE`, `ADDTRANDATA` produces the same results as the default `ADD TRANDATA` command in GGSCI by issuing the Oracle `ALTER TABLE` command with the `ADD SUPPLEMENTAL LOG GROUP` option. Oracle GoldenGate executes this command when the `CREATE TABLE` or `ALTER TABLE` is captured on the source. If you have special requirements for the supplemental logging, use the `ADD TRANDATA` command, not `DDLOPTONS ADDTRANDATA`. By default, the `ALTER TABLE` statement that adds the supplemental logging is not replicated to the target unless the `GETREPLICATES` option is in use.

For renamed tables, `ADDTRANDATA` deletes the supplemental log group for the old table and creates it for the new one. If you do not use `ADDTRANDATA` and tables will be renamed, do the following to create the log group before doing the rename:

1. Drop the supplemental log group using the database interface or the `DELETE TRANDATA` command in GGSCI.
   
   ```
   DELETE TRANDATA table_name
   ```

2. Rename the table.

3. Create the new supplemental log group using the database interface or the `ADD TRANDATA` command in GGSCI.
   
   ```
   ADD TRANDATA table_name
   ```

There might be a lag between the time when an original DDL operation occurs and when the `ADD TRANDATA` takes effect. During this time, do not allow DML operations (insert, update, delete) on the affected table if the data is to be replicated; otherwise, it will not be captured. To determine when DML can be resumed after `ADDTRANDATA`, do the following:

1. Edit the Extract parameter file in GGSCI.

---

**Caution:** Do not use the `VIEW PARAMS` or `EDIT PARAMS` command to view or edit a parameter file that was created in a character set other than that of the local operating system. View the file from outside GGSCI; otherwise, the contents may become corrupted.
2. Add the REPORT option to DDLOPTIONS, then save and close the file.

```
DDLOPTIONS [, DDLOPTIONS_option] [,...] , REPORT
```

3. Stop and start Extract to activate the parameter changes.

```
STOP EXTRACT group_name
START EXTRACT group_name
```

4. View the Extract process report.

```
VIEW REPORT group_name
```

5. Look for the ALTER TABLE statement that added the log group to the table, and make a note of the time that the command took effect. The entry looks similar to the following:

```
Successfully added TRAN DATA for table with the key, table [MYSCHEMA1.MYTABLE], operation [ALTER TABLE "MYSCHEMA1"."MYTABLE" ADD SUPPLEMENTAL LOG GROUP "GGS_MYTABLE_53475" (MYID) ALWAYS /* GOLDENGATE_DDL_REPLICATION */ ].
```

6. Permit DML operations on the new table.

The ADDTRANDATA options are:

```
ABEND
Causes Extract to abend.

RETRYOP
Causes Extract to try again based on RETRYDELAY and MAXRETRIES. Both are required when RETRYOP is used.

RETRYDELAY seconds
Sets the delay before Extract tries again. The maximum delay is 10,000 seconds.

MAXRETRIES retries
Sets the number of retries that Extract can make before abending. The maximum is 10,000 retries.

DEFAULTUSERPASSWORD password [algorithm ENCRYPTKEY {key_name | DEFAULT}]
Valid for Replicat. (Oracle only)
Can be used instead of the DEFAULTUSERPASSWORDALIAS option if an Oracle GoldenGate credential store is not being used. Specifies a different password for a replicated (CREATE | ALTER) USER name IDENTIFIED BY password statement from the one used in the source statement. Replicat will replace the placeholder that Extract writes to the trail with the specified password. When using DEFAULTUSERPASSWORD, use the NOREPLICATEPASSWORD option of DDLOPTIONS for Extract.

DEFAULTUSERPASSWORD password without options specifies a clear-text password. If the password is case-sensitive, type it that way.

Use the following options if the password was encrypted with the ENCRYPT PASSWORD command in GGSCI:

```
algorithm
Specifies the encryption algorithm that was used to encrypt the password with the ENCRYPT PASSWORD command: AES128, AES192, AES256, or BLOWFISH. Use AES unless Blowfish is required for backward compatibility. AES is more secure than Blowfish.
```
**ENCRYPTKEY** *key_name*

Specifies the logical name of a user-created encryption key in the **ENCKEYS** lookup file. Use if **ENCRYPT PASSWORD** was used with the **KEYNAME** *key_name* option, and specify the same key name.

**ENCRYPTKEY DEFAULT**

Directs Oracle GoldenGate to use a random key. Use if **ENCRYPT PASSWORD** was used with the **KEYNAME** DEFAULT option.

For more information about Oracle GoldenGate security options, see *Administering Oracle GoldenGate for Windows and UNIX*.

**CAPTUREGLOBALTEMPTABLE**

Valid for Oracle

Allows Global Temporary Tables (GTT) DDLs to be visible to Extract so that they can be replicated. By default, GTT DDLs are not visible to Extract so using **CAPTUREGLOBALTEMPTABLE** you can set Extract to include GTT DDLs that then can be filtered by the DDL statement and if passed, written to the trail. The GTT DDLs are included in Replicat, if present in trail, and are filtered by the DDL statement then if they are passed they are executed.

For trigger-version of Extract, this option is set to false regardless of whether the table is GTT or not.

**DEFAULTUSERPASSWORDALIAS** *alias [DOMAIN domain]*

Valid for Replicat. (Oracle only)

Can be used instead of the **DEFAULTUSERPASSWORD** option if an Oracle GoldenGate credential store is being used. Specifies the alias of a credential whose password replaces the one in the **IDENTIFIED BY** clause of a replicated **CREATE USER** or **ALTER USER** statement. The alias is resolved to the encrypted password in the Oracle GoldenGate credential store. Replicat replaces the placeholder that Extract writes to the trail with the resolved password before applying the DDL to the target.

When using **DEFAULTUSERPASSWORDALIAS**, use the **NOREPLICATEPASSWORD** option of DDLOPTIONS for Extract.

*alias*

Specifies the alias of the credential whose password will be used for the replacement password. This credential must exist in the Oracle GoldenGate credential store. If you are not sure what alias to use, you can inspect the content of the credential store by issuing the **INFO CREDENTIALSTORE** command. See "INFO CREDENTIALSTORE" on page 1-103.

*DOMAIN domain*

Specifies the domain that is assigned to the specified user in the credential store.

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about Oracle GoldenGate security.

**GETAPPLOPS | IGNOREAPPLOPS**

Valid for Extract. (Oracle only)

Controls whether or not DDL operations produced by business applications except Replicat are included in the content that Extract writes to a trail or file. **GETAPPLOPS** and **IGNOREAPPLOPS** can be used together with the **GETREPLICATES** and **IGNOREREPLICATES** options to control which DDL is propagated in a bidirectional or cascading configuration.
For a bidirectional configuration, use `GETAPPLOPS` with `IGNOREREPLICATES`. You also must use the `UPDATEMETADATA` option.

For a cascading configuration, use `IGNOREAPPLOPS` with `GETREPLICATES` on the systems that will be cascading the DDL operations to the target.

The default is `GETAPPLOPS`.

**GETREPLICATES | IGNOREREPLICATES**
Valid for Extract (Oracle only). Controls whether or not DDL operations produced by Replicat are included in the content that Extract writes to a trail or file. The default is `IGNOREREPLICATES`. For more information, see the `GETAPPLOPS | IGNOREREPLICOPS` options of `DDLOPTIONS`.

**IGNOREMAPPING**
Valid for Replicat. Disables the evaluation of name mapping that determines whether DDL is of `MAPPED` or `UNMAPPED` scope. This option improves performance in like-to-like DDL replication configurations, where source and target schema names and object names match, and where mapping functions are therefore unnecessary. With `IGNOREMAPPING` enabled, `MAPPED` or `UNMAPPED` scope cannot be determined, so all DDL statements are treated as `OTHER` scope. Do not use this parameter when source schemas and object names are mapped to different schema and object names on the target.

**MAPDERIVED | NOMAPDERIVED**
Valid for Replicat (Oracle and Teradata). Controls how derived object names are mapped.

**MAPDERIVED**
If a `MAP` statement exists for the derived object, the name is mapped to the name specified in that `TARGET` clause. Otherwise, the name is mapped to the name specified in the `TARGET` clause of the `MAP` statement that contains the base object. `MAPDERIVED` is the default.

**NOMAPDERIVED**
Prevents name mapping. `NOMAPDERIVED` overrides any explicit `MAP` statements that contain the name of the derived object.

For more information about how derived objects are handled during DDL replication, see the `Installing and Configuring Oracle GoldenGate for Oracle Database` or `Installing and Configuring Oracle GoldenGate for Teradata`, depending on your installation.

**MAPSCHEMAS**
Valid for Replicat (Oracle and Teradata). Use only when `MAPSESSIONSCHEMA` is used.

- `MAPSESSIONSCHEMA` establishes a source-target mapping for session schemas and is used for objects whose schemas are not qualified in the DDL.
- `MAPSCHEMAS` maps objects that do have qualified schemas in the source DDL, but which do not qualify for mapping with `MAP`, to the same session-schema mapping as in `MAPSESSIONSCHEMA`. Examples of such objects are the Oracle `CREATE TABLE AS SELECT` statement, which contains a derived object in the `AS SELECT` clause, or the Teradata `CREATE REPLICATION RULESET` statement.

This mapping takes place after the mapping that is specified in the `MAP` statement.

As an example, suppose the following DDL statement is issued on a source Oracle database:

```sql
create table a.t as select from b.t;
```
Suppose the MAP statement on the target is as follows:

```
MAP a.*, TARGET c.*;
DDLOPTIONS MAPSESSIONSCHEMA b, TARGET b1, MAPSCHEMAS
```

As a result of this mapping, Replicat issues the following DDL statement on the target:

```
create table c.t as select from b1.t;
```

- The base table gets mapped according to the TARGET clause (to schema c).
- The qualified derived object (table t in SELECT FROM) gets mapped according to MAPSESSIONSCHEMA (to schema b1) because MAPSCHEMAS is present.

Without MAPSCHEMAS, the derived object would get mapped to schema c (as specified in the TARGET clause), because MAPSESSIONSCHEMA alone only maps unqualified objects.

**MAPSESSIONSCHEMA source_schema TARGET target_schema**

Valid for Replicat (Oracle only). Enables a source session schema to be mapped to (transformed to) a different session schema on the target.

- `source_schema` is the session schema that is set with `ALTER SESSION set CURRENT_SCHEMA` on the source.
- `target_schema` is the session schema that is set with `ALTER SESSION set CURRENT_SCHEMA` on the target.

Wildcards are not supported. You can use multiple MAPSESSIONSCHEMA parameters to map different schemas.

MAPSESSIONSCHEMA overrides any mapping of schema names that is based on master or derived object names

See the example at the end of this topic for usage.

See also MAPSCHEMAS.

**NOTAG**

Valid for Replicat

Prevents the tagging of DDL that is applied by Replicat with a redo tag (either the default tag '00' or one set with the DBOPTIONS parameter with the SETTAG option). Use this option for bidirectional configurations where GETREPLICATES is used and DDL applied by Replicat must be captured back by Extract for a metadata refresh.

**PASSWORD algorithm ENCRYPTKEY (key_name | DEFAULT)**

Valid for Extract (Oracle only)

Directs Extract to encrypt all passwords in source DDL before writing the DDL to the trail.

- `algorithm` specifies the encryption algorithm to be used to encrypt the password. Valid values are AES128, AES192, AES256, or BLOWFISH. Use AES unless Blowfish is required for backward compatibility. AES is more secure than Blowfish.

- `ENCRYPTKEY key_name` specifies the logical name of a user-created encryption key in an ENCKEYS lookup file.

- `ENCRYPTKEY DEFAULT` directs Oracle GoldenGate to use a random key.
DDLOPTIONS

**REMOVECOMMENTS (BEFORE | AFTER)**
Valid for Extract and Replicat (Oracle only). Controls whether or not comments are removed from the DDL operation. By default, comments are not removed, so that they can be used for string substitution with the DDLSUBST parameter. See "DDLSUBST" on page 3-97 for more information.

**REMOVECOMMENTS BEFORE**
Removes comments before the DDL operation is processed by Extract or Replicat. They will not be available for string substitution.

**REMOVECOMMENTS AFTER**
Removes comments after they are used for string substitution.

**REPLICATEPASSWORD | NOREPLICATEPASSWORD**
Valid for Extract (Oracle only). Applies to the password in a `{CREATE | ALTER} USER user IDENTIFIED BY password` command.

- By default (REPLICATEPASSWORD), Oracle GoldenGate uses the source password in the target CREATE or ALTER statement.
- To prevent the source password from being sent to the target, use NOREPLICATEPASSWORD.

When using NOREPLICATEPASSWORD, specify a password for the target DDL statement by using a DDLOPTIONS statement with the DEFAULTUSERPASSWORD or DEFAULTUSERPASSWORDALIAS option in the Replicat parameter file.

**REPORT | NOREPORT**
Valid for Extract and Replicat (Oracle and Teradata). Controls whether or not expanded DDL processing information is written to the report file. The default of NOREPORT reports basic DDL statistics. REPORT adds the parameters being used and a step-by-step history of the operations that were processed.

**UPDATEMETADATA**
Valid for Replicat (Oracle only). Use in an active-active bi-directional configuration. This parameter notifies Replicat on the system where DDL originated that this DDL was propagated to the other system, and that Replicat should now update its object metadata cache to match the new metadata. This keeps Replicat's metadata cache synchronized with the current metadata of the local database.

**USEOWNERFORSSESSION**
Valid for Replicat (Oracle only). Forces the schema of an unqualified object in the Replicat DDL statement to be that of the Replicat session schema, instead of the schema in an ALTER SESSION SET CURRENT_SCHEMA statement, which is the default behavior.

**USEPASSWORDVERIFIERLEVEL {10|11}**
Valid for Replicat (Oracle only). Checks if the password verifier being sent in a DDL CREATE USER statement requires modifying. The reason for this check is because Oracle has different password verifiers, depending on the database version:

- 10g: A weak verifier kept in user$.password.
- 11g: The SHA-1 verifier.
- 12c: The SHA-2 and HTTP digest verifiers.

The SHA-1, SHA-2 and HTTP verifiers are captured in user$.spare4 in the format of: 'S:<SHA-1-verifier>;H:<http-verifier>;T:<SHA-2-verifier>'. Integrated Extract returns the following DDL in 12c for create user DDL statements:
In 12.0.1.0 it returns: CREATE USER username IDENTIFIED BY VALUES 'S:SHA-1;H:http;weak'.

In 12.0.2.0 and later it returns: CREATE USER username IDENTIFIED BY VALUES 'S:SHA-1;H:http;T:SHA-2;weak'.

If Replicat runs against Oracle 12c, these forms of CREATE USER are handled at the RDBMS level, but if Replicat runs against Oracle 10g or 11, these forms are not handled by the RDBMS. Oracle 10g only accepts the weak verifier, whereas Oracle 11g only accepts the $SHA-1 and weak verifiers.

To allow the CREATE USER DDL generated for an Extract connected to Oracle 12c to work with a Replicat connected to Oracle 10g or 11g, this parameter can be used to filter out the unwanted verifiers, as follows:

- If USEPASSWORDVERIFIERLEVEL is set to 10, everything except the weak verifier is filtered out of the CREATE USER DDL verification string.
- If USEPASSWORDVERIFIERLEVEL is set to 11, everything except the S:SHA-1 and weak verifiers is filtered out of the CREATE USER DDL verification string.

Examples

Example 1

The following shows how MAPSESSIONSCHEMA works to allow mapping of a source session schema to another schema on the target.

Assume the following DDL capture and mapping configurations in Extract and Replicat:

**Extract:**

```
DDL INCLUDE OBJNAME SRC.* INCLUDE OBJNAME SRC1.*
TABLE SRC.*;
TABLE SRC1.*;
DDL INCLUDE OBJNAME SRC.* INCLUDE OBJNAME SRC1.*
TABLE SRC.*;
TABLE SRC1.*;
```

**Replicat:**

```
DDLOPTIIONS MAPSESSIONSCHEMA SRC TARGET DST
DDLOPTIIONS MAPSESSIONSCHEMA SRC1 TARGET DST1
MAP SRC.*, TARGET DST.*;
MAP SRC1.*, TARGET DST1.*;
DDL INCLUDE OBJNAME DST.* INCLUDE OBJNAME DST1.*
```

Assume that the following DDL statements are issued by the logged-in user on the source:

```
ALTER SESSION SET CURRENT_SCHEMA=SRC;
CREATE TABLE tab (X NUMBER);
CREATE TABLE SRC1.tab (X NUMBER) AS SELECT * FROM tab;
```

Replicat will perform the DDL as follows (explanations precede each code segment):

```
-- Set session to DST, because SRC.* is mapped to DST.* in MAP statement.
ALTER SESSION SET CURRENT_SCHEMA=SRC;
-- Create the first TAB table in the DST schema, using the DST session schema.
CREATE TABLE DST.tab (X NUMBER);
-- Restore Replicat schema.
ALTER SESSION SET CURRENT_SCHEMA=REPUSER
```
-- Set session schema to DST, per MAPSESSIONSCHEMA, so that AS SELECT succeeds.
ALTER SESSION SET CURRENT_SCHEMA=DST;
-- Create the DST1.TAB table AS SELECT * FROM the first table (DST.TAB).
CREATE TABLE DST1.tab (X NUMBER) AS SELECT * FROM tab;
-- Restore Replicat schema.
ALTER SESSION SET CURRENT_SCHEMA=REPUSER

Without MAPSESSIONSCHEMA, the SELECT * FROM TAB would attempt to select from a non-existent SRC.TAB table and fail. The default is to apply the source schema to unqualified objects in a target DDL statement. The DDL statement in that case would look as follows and would fail:

-- Set session to DST, because SRC.* is mapped to DST.* in MAP statement.
ALTER SESSION SET CURRENT_SCHEMA=DST;
-- Create the first TAB table in the DST schema, using the DST session schema.
CREATE TABLE DST.tab (X NUMBER);
-- Restore Replicat schema.
ALTER SESSION SET CURRENT_SCHEMA=REPUSER
-- Set session schema to SRC, because TAB in the AS SELECT is unqualified
-- and SRC is the source session schema.
ALTER SESSION SET CURRENT_SCHEMA=SRC;
-- Create DST1.TAB AS SELECT * from SRC.TAB (SRC=current session schema).
CREATE TABLE DST1.tab (X NUMBER) AS SELECT * FROM tab;
-- SRC.TAB does not exist.
-- Abend with an error unless the error is handled by a DDLERROR statement.

Example 2
The following shows how to use DEFAULTUSERPASSWORDALIAS to specify a different password for a replicated (CREATE | ALTER) USER name IDENTIFIED BY password statement from the one used in the source statement. In this example, the alias ddlalias is in the target domain in the credential store.

DDLOPTIONS DEFAULTUSERPASSWORDALIAS ddlalias DOMAIN target
DDLSUBST

Valid For

Extract and Replicat

Description

Use the DDLSUBST parameter to substitute strings in a DDL operation. For example, you could substitute one table name for another or substitute a string within comments. The search is not case-sensitive. To represent a quotation mark in a string, use a double quote mark.

Guidelines for Using DDLSUBST

- Do not use DDLSUBST to convert column names and data types to something different on the target. Changing the structure of a target object in this manner will cause errors when data is replicated to it. Likewise, do not use DDLSUBST to change owner and table names in a target DDL statement. Always use a MAP statement to map a replicated DDL operation to a different target object.

- DDLSUBST always executes after the DDL parameter, regardless of their relative order in the parameter file. Because the filtering executes first, use filtering criteria that is compatible with the criteria that you are using for string substitution. For example, consider the following parameter statements:

  DDL INCLUDE OBJNAME fin.*
  DDLSUBST 'cust' WITH 'customers' INCLUDE OBJNAME sales.*

  In this example, no substitution occurs because the objects in the INCLUDE and DDLSUBST statements are different. The fin-owned objects are included in the Oracle GoldenGate DDL configuration, but the sales-owned objects are not.

- You can use multiple DDLSUBST parameters. They execute in the order listed in the parameter file.

- For Oracle DDL that includes comments, do not use the DDLOPTONS parameter with the REMOVECOMMENTS BEFORE option if you will be doing string substitution on those comments. REMOVECOMMENTS BEFORE removes comments before string substitution occurs. To remove comments, but allow string substitution, use the REMOVECOMMENTS AFTER option.

- There is no maximum string size for substitutions, other than the limit that is imposed by the database. If the string size exceeds the database limit, the Extract or Replicat process that is executing the operation abends.

Default

No substitution

Syntax

DDLSUBST 'search_string' WITH 'replace_string'
[INCLUDE inclusion_clause | EXCLUDE exclusion_clause]
'search_string'
The string in the source DDL statement that you want to replace. Enclose the string within single quote marks. To represent a quotation mark in a string, use a double quotation mark.

WITH
Required keyword.

'replace_string'
The string that you want to use as the replacement in the target DDL. Enclose the string within single quote marks. To represent a quotation mark in a string, use a double quotation mark.

INCLUDE inclusion_clause | EXCLUDE exclusion_clause
Specifies one or more INCLUDE and EXCLUDE statements to filter the DDL operations for which the string substitution rules are applied. See "DDL Filtering Options" on page 3-78 for syntax and usage.

Examples

Example 1
The following replaces the string cust with the string customers for tables in the fin schema.

```
DDLSUBST 'cust' WITH 'customers'
INCLUDE ALL OBJTYPE 'table' OBJNAME fin.*
```

Example 2
The following substitutes a new directory only if the DDL command includes the word logfile. If the search string is found multiple times, the replacement string is inserted multiple times.

```
DDLSUBST '/file1/location1' WITH '/file2/location2' INCLUDE INSTR 'logfile'
```

Example 3
The following uses multiple DDLSUBST statements, which execute in the order shown.

```
DDLSUBST 'a' WITH 'b' INCLUDE ALL
DDLSUBST 'b' WITH 'c' INCLUDE ALL
```

The net effect of the preceding substitutes all a and b strings with c.
DDLRULEHINT

Description
Use the DDLRULEHINT parameter to add a RULE hint to the DDL trigger. For example you can add the RULE (/*NO_UNNEST*/) hint to improve the performance of the trigger when performing SQL queries.

You can also use the define _ddl_rule_hint parameter in the params.sql file to add a hint. For example: define _ddl_rule_hint = '/*NO_UNNEST*/'

Default
None

Syntax
DDLRULEHINT hint_syntax

hint_syntax
The syntax of the hint. Spaces are not permitted within the hint syntax.

Example
DDLRULEHINT /*NO_UNNEST*/
DDLTABLE

Valid For

GLOBALS

Description

Use the DDLTABLE parameter to specify the name of the DDL history table, if other than the default of GGS_DDL_HIST. The DDL history table stores a history of DDL operations processed by Oracle GoldenGate.

The name of the history table must also be specified with the ddl_hist_table parameter in the params.sql script. This script resides in the root Oracle GoldenGate installation directory.

This parameter is only valid for an Oracle database in which the capture configuration uses the Oracle GoldenGate DDL trigger to support DDL replication. For more information about the Oracle GoldenGate DDL objects, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Default

GGS_DDL_HIST

Syntax

DDLTABLE table_name

table_name
The fully qualified name of the DDL history table. This can be a two-part name (schema.table) or a three-part name, if stored in a container database (container.schema.table).

Example

DDLTABLE GG_DDL_HISTORY
DECERTTRAIL

Valid For

Extract data pump and Replicat.

Description

Use the DECERTTRAIL parameter to decrypt data in a trail or extract file. This parameter is required in the following cases:

- If the trail was encrypted with the master key and wallet method, use DECERTTRAIL for a data pump only if you want the data to be decrypted when written to the output trail of the data pump. Otherwise, this parameter is not needed. If the data-pump requires further processing of records, it decrypts automatically and then re-encrypts the data before writing it to the output trail. Replicat always decrypts data automatically when the master key and wallet method is used.

- If the trail was encrypted with the ENCKEYS method, use DECERTTRAIL for a data pump if the NOPASSTHRU parameter is being used. When DECERTTRAIL is used for a data pump, use the ENCRYPTTRAIL parameter before specifying any output trails that must be encrypted.

- If the trail was encrypted with the ENCKEYS method, use DECERTTRAIL for Replicat to decrypt the data before applying it to the target.

Data encryption is controlled by the ENCRYPTTRAIL | NOENCRYPTTRAIL parameters. See Administering Oracle GoldenGate for Windows and UNIX for more information about trail or file encryption.

Default

None.

Syntax

DECERTTRAIL {(AES128 | AES192 | AES256) [KEYNAME key_name]}

DECERTTRAIL

Valid without any other options only if the trail or file was encrypted with ENCRYPTTRAIL without options to use 256-key byte substitution.

{(AES128 | AES192 | AES256)}

Valid for master key and wallet method and ENCKEYS method. Specify the same AES cipher that was used in ENCRYPTTRAIL to encrypt the trail or file.

KEYNAME key_name

Valid for the ENCKEYS method. Specifies the logical key name that was used in the ENCRYPTTRAIL statement. This key must exist in a local ENCKEYS lookup file.

Example

Example 1

The following is an example of the ENCKEYS method.

DECERTTRAIL AES192, KEYNAME mykey1
Example 2
The following is all that is needed to decrypt using the master key and wallet method.

DECRYPTTRAIL
DEFERAPPLYINTERVAL

Valid For
Replicat

Description
Use the DEFERAPPLYINTERVAL parameter to set an amount of time that Replicat waits before applying captured transactions to the target database. To determine when to apply the transaction, Replicat adds the delay value to the commit timestamp of the source transaction, as recorded in the local GMT time of the source system.

You can use DEFERAPPLYINTERVAL for such purposes as to prevent the propagation of erroneous changes made to the source data, to control data arrival across different time zones, and to allow time for other planned events to occur before the data is applied to the target. Note that by using DEFERAPPLYINTERVAL, you are purposely building latency into the target data, and it should be used with caution if the target applications are time-sensitive.

To find out if Replicat is deferring operations, use the SEND REPLICAT command with the STATUS option and look for a status of Waiting on deferred apply.

**Note:** If the TCPSOURCETIMER parameter is in use, it is possible that the timestamps of the source and target transactions could vary by a few seconds, causing Replicat to hold its transaction (and hence row locks) open for a few seconds. This small variance should not have a noticeable affect on performance.

Default
0 (no delay)

Syntax
DEFERAPPLYINTERVAL \( n \) unit

\( n \)
A numeric value for the amount of time to delay. The minimum delay time is the value that is set for the EOFDELAY parameter. The maximum delay time is seven days.

**unit**
The unit of time for the delay. Can be:

S | SEC | SECS | SECOND | SECONDS | MIN | MINS | MINUTE | MINUTES | HOUR | HOURS | DAY | DAYS

Example
This example directs Replicat to wait ten hours before posting its transactions.

DEFERAPPLYINTERVAL 10 HOURS

If a transaction completes at 08:00:00 source GMT time, and the delay time is 10 hours, the transaction will be applied to the target at 18:00:00 target GMT time the same day.
DEFSFILE

Valid For

DEFGEN

Description

Use the DEFSFILE parameter to identify the name of the file to which DEFGEN will write data definitions. By default, the data definitions file is written in the character set of the local operating system. You can change the character set with the CHARSET option.

For more information about definitions files, see Administering Oracle GoldenGate for Windows and UNIX.

Default

None

Syntax

DEFSFILE file_name [APPEND | PURGE] [CHARSET character_set] [FORMAT RELEASE major.minor]

file_name

The relative or fully qualified file name. The file is created when you run DEFGEN.

APPEND

Directs DEFGEN to write new content (from the current run) at the end of any existing content, if the specified file already exists. If the definitions file already exists, but is of an older Oracle GoldenGate release version, you can set the FORMAT RELEASE option to the same version as the existing file to prevent errors. Otherwise, DEFGEN will try to add newer metadata features and abend. The following are the restrictions when using APPEND:

- If the existing data definitions file is in a format older than Oracle GoldenGate 11.2.1, DEFGEN appends the table definitions in the old format, where table and column names with multi-byte and special characters are not supported.
- If the existing data definitions file is in the newer format introduced in version 11.2.1, DEFGEN appends the table definitions in the existing character set of the file.
- If the existing file is from version 11.2 or earlier, it was written when DEFGEN did not support three-part object names and will cause an error if the new metadata contains three-part names. You can specify objects from an Oracle container database or SQL/MX if you remove the container or catalog portion by using the NOCATALOG parameter in the DEFGEN parameter file.

PURGE

Directs DEFGEN to purge the specified file before writing new content from the current run. This is the default. When using PURGE, you can overwrite an existing definitions file that was created by an older version of DEFGEN with newer metadata that supports newer features, such as three-part object names.

CHARSET character_set

Generates the definitions file in the specified character set. Without CHARSET, the default character set of the operating system is used. If APPEND mode is specified for a
definitions file that is version 11.2.1 or later, \texttt{CHARSET} is ignored, and the character set of the existing definitions file is used.

\textbf{FORMAT RELEASE \textit{major}\textunderscore \textit{minor}}

Specifies the metadata format of the definitions that are sent by DEFGEN to the definitions file. The metadata tells the reader process whether the file records are of a version that it supports. The metadata format depends on the version of the Oracle GoldenGate process. Older Oracle GoldenGate versions contain different metadata than newer ones. Use \textbf{FORMAT} when the definitions file will be used by a process that is of an older Oracle GoldenGate version than the current one.

- \textbf{FORMAT} is a required keyword.
- \textbf{RELEASE} specifies an Oracle GoldenGate release version. \textit{major} is the major version number, and \textit{minor} is the minor version number. The \textit{X.x} must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate \textit{X.x} version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.)

The release version is programmatically mapped back to an appropriate internal compatibility level. The default is the current version of the process that writes to this trail. Note that \textbf{RELEASE} versions earlier than 12.1 do not support three-part object names.

\textbf{Example}

\begin{verbatim}
DEFSFILE ./dirdef/orcldef CHARSET ISO-8859-11 FORMAT RELEASE 11.2
\end{verbatim}
DISCARDFILE | NODISCARDFILE

Valid For

Extract and Replicat

Description

Use the DISCARDFILE parameter to do the following:

- Customize the name, location, size, and write mode of the discard file. By default, a discard file is generated whenever a process is started with the START command through GGSCI. To retain the default properties, a DISCARDFILE parameter is not required.
- Specify the use of a discard file for processing methods where the process starts from the command line of the operating system and a discard file is not created by default.

Use the NODISCARDFILE parameter to disable the use of a discard file. If NODISCARDFILE is used with DISCARDFILE, the process abends.

When using DISCARDFILE, use either the PURGE or APPEND option. Otherwise, you must specify a different discard file name before starting each process run, because Oracle GoldenGate will not write to an existing discard file without one of these instructions and will terminate.

See "DISCARDROLLOVER" on page 3-108 for how to control how often the discard file is rolled over to a new file.

For more information about the discard file, see Administering Oracle GoldenGate for Windows and UNIX.

Default

If a process is started with the START command in GGSCI, generate a discard file by default as follows:

- The file is named after the process that creates it, with a .dsc extension. If the process is a coordinated Replicat, generate one file per thread. Each file name is appended with the thread ID of the corresponding thread.
- The file is created in the dirrpt sub-directory of the Oracle GoldenGate installation directory.
- The maximum file size is 50 megabytes.
- At startup, if a discard file exists, it is purged before new data is written.

If a process is started from the command line of the operating system, do not generate a discard file by default.

Syntax

DISCARDFILE { [file_name]
 [, APPEND | PURGE]
 [, MAXBYTES n | MEGABYTES n] } |
NODISCARDFILE

DISCARDFILE
Indicates that the name or other attribute of the discard file is being changed.
file_name
The relative or fully qualified name of the discard file, including the actual file name. For a coordinated Replicat, specify a file name of up to five characters, because each file name is appended with the thread ID of the thread that writes it. To store the file in the Oracle GoldenGate directory, a relative path name is sufficient, because Oracle GoldenGate qualifies the name with the Oracle GoldenGate installation directory.

APPEND
Adds new content to existing content if the file already exists. If neither APPEND nor PURGE is used, you must specify a different discard file name before starting each process run.

PURGE
Purges the file before writing new content. If neither PURGE nor APPEND is used, you must specify a different discard file name before starting each process run.

MAXBYTES \( n \)
Sets the maximum size of the file in bytes. The valid range is from 1 to 2147483646. The default is 50000000. If the specified size is exceeded, the process abends.

MEGABYTES \( n \)
Sets the maximum size of the file in megabytes. The valid range is from 1 to 2147. The default is 50 MB. If the specified size is exceeded, the process abends.

NODISCARDFILE
Prevents the process from creating a discard file.

Example

Example 1
This example specifies a non-default file name and extension, non-default write mode, and non-default maximum file size. This example shows how you could change the default properties of a discard file for an online (started through GGSCI) process or specify the use of a discard file for a process that starts from the command line of the operating system and has no discard file by default.

DISCARDFILE .dirrpt/discard.txt, APPEND, MEGABYTES 20

Example 2
This example changes only the write mode of the default discard file for an online process (started through GGSCI).

DISCARDFILE .dirrpt/finance.dsc, APPEND

Example 3
This example disables the use of a discard file for an online process (started through GGSCI).

NODISCARDFILE
DISCARDROLLOVER

Valid For
Extract and Replicat

Description
Use the DISCARDROLLOVER parameter to set a schedule for aging discard files. For long or continuous runs, setting an aging schedule prevents the discard file from filling up and causing the process to abend, and it provides a predictable set of archives that can be included in your archiving routine.

When the DISCARDROLLOVER age point is reached, a new discard file is created, and old files are renamed in the format of GROUPn.extension, where:

- GROUP is the name of the Extract or Replicat group.
- n is a number that gets incremented by one each time a new file is created, for example: myext0.dsc, myext1.dsc, myext2.dsc, and so forth.
- extension is the file extension, such as .dsc.

You can specify a time of day, a day of the week, or both. Specifying just a time of day (AT option) without a day of the week (ON option) generates a discard file at the specified time every day.

Discard files always roll over at the start of a process run, regardless of whether DISCARDROLLOVER is used or not.

If the NODISCARDFILE parameter is used with the DISCARDROLLOVER parameter, the process abends.

For more information about the discard file, see Administering Oracle GoldenGate for Windows and UNIX.

Default
Disabled. By default, discard files are rolled over when a process starts.

Syntax
DISCARDROLLOVER
{AT hh:mm | ON day | AT hh:mm ON day}

AT hh:mm
The time of day to age the file.

Valid values:
- hh is an hour of the day from 00 through 23.
- mm is minutes from 00 through 59.

ON day
The day of the week to age the file.

Valid values:
SUNDAY
They are not case-sensitive.

Examples

Example 1
DISCARDROLLOVER AT 05:30

Example 2
DISCARDROLLOVER ON friday

Example 3
DISCARDROLLOVER AT 05:30 ON friday
DOWNCRITICAL

Valid For
Manager

Description
Use the DOWNCRITICAL parameter to include processes that abended or stopped normally in the report that is generated by the DOWNREPORT parameter.

Default
None

Syntax

DOWNCRITICAL
DOWNREPORT

Valid For

Manager

Description

Use the DOWNREPORTMINUTES or DOWNREPORTHOURS parameter to specify the frequency with which Manager reports Extract and Replicat processes that are not running. Whenever a process starts or stops, events are generated to the error log, and those messages can easily be overlooked if the log is large. DOWNREPORTMINUTES and DOWNREPORTHOURS report on a periodic basis to ensure that you are aware of stopped processes.

If DOWNREPORT is explicitly indicated and the value of the CHECKMINUTES parameter is greater than that of DOWNREPORT, then CHECKMINUTES acquires the value of DOWNREPORT.

To report on running processes, use the UPREPORT parameter.

Default

Do not report down processes.

Syntax

DOWNREPORTMINUTES minutes | DOWNREPORTHOURS hours

minutes
The frequency, in minutes, to report processes that are not running.

hours
The frequency, in hours, to report processes that are not running.

Example

The following generates a report every 30 minutes.

DOWNREPORTMINUTES 30
DSOPTIONS

Valid For

Extract

Description

Use the DSOPTIONS parameter to specify processing options for an Extract that uses a Teradata Access Module (TAM). For more information about configuring Oracle GoldenGate for Teradata extraction, see Installing and Configuring Oracle GoldenGate for Teradata. Use of this parameter is identical to using the TRANLOGOPTIONS parameter so many of the options are described in "TRANLOGOPTIONS" on page 3-364.

Default

None

Syntax

DSOPTIONS
[CHECKOPCOMPLETE]
[CHECKTRANDATA]
[COMMITTEDTRANLOG]
[CREATETRANLOG]
[EXCLUDETRANS]
[EXCLUDEUSER]
[GETMETADATAFROMVAM]
[IGNOREMETADATAFROMVAM]
[NOCHECKPOINTERROR]
[NOCHECKTRANDATA]
[RESTARTAPPEND]
[VAMCOMPATIBILITY]

COMMITTEDTRANLOG
(Maximum performance mode) Specifies that transaction data will not be persisted to disk. The TAM sends transaction data changes to an Extract process that saves it to a regular Oracle GoldenGate trail in transaction commit order. The trail can be read by Replicat or by a data pump Extract group.

CREATETRANLOG
(Maximum protection mode) Causes Extract to create a VAM trail, which is a local trail to which transaction data changes are persisted for further processing by a VAM-sort Extract. Data is written to the VAM trail in log-style format which interleaves change records from different transactions. Use this option for the primary Extract process that interfaces with a Teradata Access Module (TAM) and writes to the VAM trail. Specify the VAM trail with the ADD EXTTRAIL command in GGSCI.

SORTTRANLOG
(Maximum protection mode) Indicates that Extract needs to perform transaction sorting functions. Use this option for a VAM-sort Extract group that reads a VAM trail that is populated by a primary Extract process. The VAM-sort Extract sorts the interleaved operations into the correct prepare/commit/rollback transactional units before further processing by Oracle GoldenGate.
RESTARTAPPEND
(Maximum performance mode and maximum protection mode) Directs Extract to append data to the end of the Oracle GoldenGate trail upon restart, rather than rewriting data that was written in a previous run. Use this option with the COMMITTEDTRANLOG or CREATETRANLOG argument.

VAMCOMPATIBILITY 1
(Maximum performance mode and maximum protection mode) A value of 1 means the original VAM API metadata structure is being used. This structure was originally created for Teradata, which is a separate implementation from the other databases, and Teradata still uses this level. To maintain backwards compatibility with Extract, it may be necessary to manually set VAMCOMPATIBILITY to 1 if running an earlier version of a TAM module against the later releases of Extract that contain VAM versioning. Extract abends with a message if VAMCOMPATIBILITY 1 is required and not set.
DYNAMICPORTLIST

Valid For
Manager

Description
Use the DYNAMICPORTLIST parameter to specify a list of available ports to which the following local Oracle GoldenGate processes can bind for communication with a remote Oracle GoldenGate process:

- Collector: to communicate with a remote Extract to receive incoming data.
- Replicat: to communicate with a remote Extract to receive data during an initial load task.
- Passive Extract: to communicate with a remote Collector
- GGSCI: to issue remote commands

Specify enough ports to accommodate expansion of the number of processes without having to stop and restart Manager to add them to the list. You can specify an individual port, a range of ports, or both.

Default
None

Syntax
DYNAMICPORTLIST (port | port-port) [ , ...]

port
A port number that can be allocated. The maximum number of port entries is 5000.

- To specify multiple ports, use a comma-delimited list. Example:
  7830, 7833

- To specify a range of ports, use a dash (-) to separate the first and last port in the range. Do not put any spaces before or after the dash. Example:
  7830-7835

- To specify a range of ports plus an individual port, place a comma between the range and the individual port number. Example:
  7830-7835, 7839

Example
DYNAMICPORTLIST 7820-7830, 7833, 7835
DYNAMICRESOLUTION | NODYNAMICRESOLUTION

Valid For

Extract and Replicat

Description

Use the DYNAMICRESOLUTION and NODYNAMICRESOLUTION parameters to control how table names are resolved.

DYNAMICRESOLUTION, the default, enables fast process startup when there are numerous tables specified in TABLE or MAP statements. To get metadata for transaction records that it needs to process, Oracle GoldenGate queries the database and then builds a record of the tables that are involved. DYNAMICRESOLUTION causes the record to be built one table at a time, instead of all at once. The metadata of any given table is added when Extract first encounters the object ID in the transaction log, while record-building for other tables is deferred until their object IDs are encountered. DYNAMICRESOLUTION is the same as WILDCARDRESOLVE DYNAMIC.

NODYNAMICRESOLUTION causes the entire object record (for all tables) to be built at startup, which can be time-consuming if the database is large. This option is not supported for Teradata. NODYNAMICRESOLUTION is the same as WILDCARDRESOLVE IMMEDIATE.

See “WILDCARDRESOLVE” on page 3-421 for more information.

Default

DYNAMICRESOLUTION

Syntax

DYNAMICRESOLUTION | NODYNAMICRESOLUTION
EBCDICTOASCII

Valid For

Extract data pump and Replicat

Description

Use the EBCDICTOASCII parameter to convert character data in the input trail from EBCDIC to ASCII format when sending it to a DB2 target database on a z/OS system. This parameter can be specified to request conversion of all EBCDIC columns and user token data to ASCII. This parameter must precede the SOURCEDB parameter. This parameter is only needed if the input trail file was created by an Extract version prior to v10.0. It is ignored for all other cases, because the conversion is done automatically. As of version 11.2.1, conversion is not allowed by a data pump.

Default

None

Syntax

EBCDICTOASCII
ENABLECATALOGNAMES

Valid For

GLOBAL

Description

Use the ENABLECATALOGNAMES to enable Oracle GoldenGate support for three-part object names in SQL/MX databases. A three-part name includes the catalog with the schema and object name. USEENABLECATALOGNAMES is ignored for all other databases.

Default

Disabled

Syntax

ENABLECATALOGNAMES
ENABLEMONITORING

Valid For

GLOBALS

Description

Use the ENABLEMONITORING parameter to enable the monitoring of Oracle GoldenGate instances from Oracle GoldenGate Monitor. It directs Manager to publish the monitoring points that provide status and other information to the Oracle GoldenGate Monitor clients. See "Summary of Oracle GoldenGate Data Store Commands" on page 1-6 for commands that control the Java agent that sends the information from the monitoring points to the Oracle GoldenGate Monitor Server.

Before enabling monitoring on any given platform, see Administering Oracle GoldenGate Monitor to make certain that the operating system is supported. That guide also contains instructions for installing and configuring Oracle GoldenGate Monitor. For help with using Oracle GoldenGate Monitor, see the online help.

This parameter is not valid for NonStop or SQL/MX.

---

**Note:** When monitoring is enabled on a UNIX system for a high number of Oracle GoldenGate processes (approximately 400), the system-imposed limit on the maximum amount of allowed shared memory may be exceeded. The message returned by Manager is similar to this:

WARNING OGG-01934  Datastore repair failed" reported during "start...

If this occurs, increase the kernel parameter kernel.shmmax by 8 times the default for the operating system.

---

Default

Disabled

Syntax

ENABLEMONITORING
ENCRYPTTRAIL | NOENCRYPTTRAIL

Valid For
Extract

Description
Use the ENCRYPTTRAIL and NOENCRYPTTRAIL parameters to control whether Oracle GoldenGate encrypts or does not encrypt data that is written to a trail or extract file.

ENCRYPTTRAIL supports the following encryption methods:

- **Master key and wallet method**: Generate a one-time AES key for each trail file and uses it to encrypt the contents. Then, the one-time key is encrypted by the master-key and stored in the trail file header.

- **ENCKEYS method**: Generate a AES encryption key, store it under a given name in an ENCKEYS file, and configure Oracle GoldenGate to use that key to directly encrypt or decrypt the contents of the trail file.

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about these encryption methods. ENCRYPTTRAIL requirements are different for these methods.

You can use encryption for local and remote trails that are specified with the following parameters in an Extract parameter file:

- **RMTTRAIL**
- **EXTRAIL**

You can use encryption for local and remote extract files that are specified with the following parameters in an Extract parameter file:

- **RMTFILE**
- **EXTFILE**

ENCRYPTTRAIL and NOENCRYPTTRAIL are trail or file-specific. One affects all subsequent trail or extract file specifications in the parameter file until the other parameter is encountered. The parameter must be placed before the parameter entry for the trail that it will affect.

ENCRYPTTRAIL and NOENCRYPTTRAIL cannot be used when FORMATASCII is used to write data to a file in ASCII format. The trail or file must be written in the default Oracle GoldenGate canonical format.

ENCRYPTTRAIL encrypts the trail data across all data links and within the files themselves. Only the data blocks are encrypted. User tokens are not encrypted.

Default
NOENCRYPTTRAIL

Syntax

```
ENCRYPTTRAIL [(AES128 | AES192 | AES256) [KEYNAME key_name]] | NOENCRYPTTRAIL]
```

ENCRYPTTRAIL without options uses AES128 as the default for all database types except the iSeries, z/OS, and NonStop platforms, where BLOWFISH is the default. AES is not supported on those platforms.
{AES128 | AES192 | AES256}
Specifies the Advanced Encryption Standard (AES) encryption key length to use. This is a symmetric-key encryption standard that is used by governments and other organizations that require a high degree of data security. This option is not supported by the iSeries, z/OS, and NonStop platforms.

For both the master key and wallet method and the `ENCKEYS` method, you must specify one of the AES ciphers to encrypt the file(s):

- **AES128** has a 128-bit block size with a key size of 128 bits.
- **AES192** has a 128-bit block size with a key size of 192 bits.
- **AES256** has a 128-bit block size with a key size of 256 bits.

To use AES encryption for any database other than Oracle on a 32-bit platform, the path of the `lib` sub-directory of the Oracle GoldenGate installation directory must be specified as an environment variable before starting any processes. This is not required on 64-bit platforms. Set the path as follows:

- **UNIX**: Specify the path as an entry to the `LD_LIBRARY_PATH` or `SHLIB_PATH` variable. For example:
  ```
  setenv LD_LIBRARY_PATH ./lib:$LD_LIBRARY_PATH
  ```
- **Windows**: Add the path to the `PATH` variable.

You can use the `SETENV` parameter to set it as a session variable for the process.

**KEYNAME key_name**
Specifies that the `ENCKEYS` method of encryption will be used. Not valid for the master key and wallet method. For `key_name`, specify the logical name of the user-defined encryption key. Oracle GoldenGate uses the key name to look up the actual key in the `ENCKEYS` lookup file. To use the `ENCKEYS` method, you must:

- Generate the encryption key.
- Store it in an `ENCKEYS` lookup file.
- Copy `ENCKEYS` to every system where encryption or decryption (or both) are performed.

**NOENCRYPTTRAIL**
Prevents the trail from being encrypted. This is the default.

**Examples**

**Example 1**
In the following example, the master key and wallet method is used. The Extract process writes to two trails. The data for the `emp` table is written to trail `/home/ggsora/dirdat/em`, which is encrypted with the AES-192 cipher. The data for the `stores` table is written to trail `/home/ggsora/dirdat/st`, which is not encrypted.

````
ENCRYPTTRAIL AES192
RMTTRAIL /home/ggsora/dirdat/em
TABLE hr.emp;
NOENCRYPTTRAIL
RMTTRAIL /home/ggsora/dirdat/st
TABLE ops.stores;
```

Example 2
As an alternative to the preceding example, you can omit NOENCRYPTTRAIL if you list all non-encrypted trails before the ENCRYPTTRAIL parameter.

```
RMTTRAIL /home/ggsora/dirdat/st
TABLE ops.stores;
ENCRYPTTRAIL AES192
RMTTRAIL /home/ggsora/dirdat/em
TABLE hr.emp;
```

Example 3
In the following example, the ENCKEYS method is used.

```
ENCRYPTTRAIL AES192, KEYNAME mykey1
RMTTRAIL /home/ggsora/dirdat/em
TABLE hr.emp;
TABLE ops.stores;
```
Valid For

Replicat

Description

Use the END parameter to terminate Replicat when it encounters the first record in the data source whose timestamp is the specified point in time.

Without END, the process runs continuously until:

- the end of the transaction log or trail is reached, at which point it will stop gracefully.
- manually terminated from the command shell.

Use END with the SPECIALRUN parameter to post data as a point-in-time snapshot, rather than continuously updating the target tables.

Default

Continuous processing

Syntax

END {date [time] | RUNTIME}

date [time]
Causes Replicat to terminate when it reaches a record in the data source whose timestamp exceeds the one that is specified with this parameter.

Valid values:

- date is a date in the format of yyyy-mm-dd.
- time is the time in the format of hh:mm[:ss[.cccccc]] based on a 24-hour clock.

RUNTIME
Causes Replicat to terminate when it reaches a record in the data source whose timestamp exceeds the current date and clock time. All unprocessed records with timestamps up to this point in time are processed. One advantage of using RUNTIME is that you do not have to alter the parameter file to change dates and times from run to run. Instead, you can control the process start time within your batch programming.

Examples

Example 1
SPECIALRUN
END 2010-12-31 17:00:00

Example 2
SPECIALRUN
END RUNTIME
**EOFDELAY | EOFDELAYCSECS**

**Valid For**

Extract and Replicat

**Description**

Use the `EOFDELAY` or `EOFDELAYCSECS` parameter to control how often Extract, a data pump, or Replicat checks for new data after it has reached the end of the current data in its data source. You can reduce the system I/O overhead of these reads by increasing the value of this parameter.

---

**Note:** Large increases can increase the latency of the target data, especially when the activity on the source database is low

This parameter is not valid when `SOURCEISTABLE` is used. This parameter cannot be set to zero (0).

**Default**

The minimum is 1 second; the maximum is 60 seconds.

**Syntax**

```
EOFDELAY seconds | EOFDELAYCSECS centiseconds
```

- `seconds`
  The delay, in seconds, before searching for data to process.

- `centiseconds`
  The delay, in centiseconds, before searching for data to process.

**Example**

```
EOFDELAY 3
```
EXCLUDETAG

Valid For

(Oracle) Valid for Extract and Replicat or data pump.

Description

Use `EXCLUDETAG` tag in your data pump or Replicat parameter file to specify changes to be excluded from trail files. The limitation for this parameter is that the tag value can be up to 2000 hexadecimal digits (0-9A-F) or the plus sign (+). You can have multiple `EXCLUDETAG` lines, but each `EXCLUDETAG` should have a single value. By default, Replicat the individual records every change it applies to the database by 00 in both classic mode or integrated mode.

Compare with older versions, new trail file contains tag tokens, which would not introduce problems for older trail readers.

Use `EXCLUDETAG` + to ignore the individual records that are tagged with any redo tag.

To tag the individual records, use the `DBOPTIONS` parameter with the `SETTAG` option in the Replicat parameter file. Use these parameters to prevent cycling (loop-back) of Replicat the individual records in a bi-directional configuration or to filter other transactions from capture. The default `SETTAG` value is 00. Valid value is any single Oracle Streams tag. A tag value can be up to 2000 hexadecimal digits (0-9 A-F) long. For more information about Streams tags, see *Oracle Streams Replication Administrator’s Guide*.

Default

None

Syntax

```
[EXCLUDETAG [tag | NULL] | [*]
```

Example 1

For Replicat:
```
excludetag tag
```

Example 2

For data pumps:
```
excludetag 00
```
EXCLUDEWILDCARDOBJECTSONLY

Valid For

GLOBAL

Description

Use the EXCLUDEWILDCARDOBJECTSONLY parameter to force the inclusion of non-wildcarded source objects specified in TABLE or MAP parameters when an exclusion parameter contains a wildcard that otherwise would exclude that object. Exclusion parameters are CATALOGEXCLUDE, SCHEMAEXCLUDE, MAPEXCLUDE, and TABLEEXCLUDE.

The exclusion parameters get evaluated and satisfied before the TABLE or MAP statements. Without EXCLUDEWILDCARDOBJECTSONLY, it would be possible for an object in a TABLE or MAP statement to be wrongly excluded because it satisfies the wildcard in the exclude specification. For EXCLUDEWILDCARDOBJECTSONLY to work on an object, that object must be explicitly named without using wildcards in any of the name components.

Default

None

Syntax

EXCLUDEWILDCARDOBJECTSONLY

Example

In this example, schema1.src_table1 is included in processing because the TABLEEXCLUDE parameter is wildcarded and the TABLE specification is not wildcarded. Without EXCLUDEWILDCARDOBJECTSONLY, schema1.src_table1 would be excluded because of the wildcard specification in TABLEEXCLUDE.

TABLEEXCLUDE schema1.src_table*;
TABLE schema1.src_table1;
EXTFILE

Valid For
Extract and Replicat

Description
Use the EXTFILE parameter to specify an extract file, which is a local file that will be read by a data pump Extract group on the local system, or to specify a local extract file that Replicat reads when SPECIALRUN is used.

EXTFILE must precede all associated TABLE or MAP statements. Multiple EXTFILE statements can be used to define different files.

You can encrypt the data in this file by using the ENCRYPTTRAIL parameter. See "ENCRYPTTRAIL | NOENCRYPTTRAIL" on page 3-119 for more information.

Default
None

Syntax
EXTFILE file_name
[, FORMAT RELEASE major.minor]
[, MAXFILES number]
[, MEGABYTES megabytes]
[, TRAILBYTEORDER {BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN}]

file_name
Valid for Extract and Replicat. Specifies the relative or fully qualified name of the extract file.

FORMAT RELEASE major.minor
Specifies the metadata format of the data that is sent by Extract to a trail, a file, or (if a remote task) to another process. The metadata tells the reader process whether the data records are of a version that it supports. The metadata format depends on the version of the Oracle GoldenGate process. Older Oracle GoldenGate versions contain different metadata than newer ones.

- FORMAT is a required keyword.
- RELEASE specifies an Oracle GoldenGate release version. major is the major version number, and minor is the minor version number. The X.x must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate X.x version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.) The release version is programmatically mapped back to the appropriate trail format compatibility level. The default is the current version of the process that writes to this trail. Note that RELEASE versions earlier than 12.1 do not support three-part object names.

There is a dependency between FORMAT and the RECOVERYOPTIONS parameter. When RECOVERYOPTIONS is set to APPENDMODE, FORMAT must be set to RELEASE 10.0 or greater. When RECOVERYOPTIONS is set to OVERWRITEMODE, FORMAT must be set to RELEASE 9.5 or less. See "RECOVERYOPTIONS" on page 3-224 for more information.
MAXFILES number
Valid for Extract. Forces a sequence of files to be created, rather than a single file. Use when you expect the size of a file to exceed the limit permitted by the operating system. MAXFILES permits as many files to be created as needed. Aged files are appended with a six-digit sequence number, for example datafile000002. Checkpoints are not maintained in these files. When using MAXFILES, also use MEGABYTES to set the maximum size of each file in the sequence.

MEGABYTES megabytes
Valid for Extract. Defines the maximum size of the file (or of each file created when MAXFILES is used). The size of an extract file cannot exceed 2GB.

TRAILBYTEORDER (BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN)
Sets the byte format of the metadata in the file records. This parameter does not affect the column data. Valid only for files that have a FORMAT RELEASE version of at least 12.1. Valid values are BIGENDIAN (big endian), LITTLEENDIAN (little endian), and NATIVEENDIAN (default of the local system). The default is BIGENDIAN. See the GLOBALS version of TRAILBYTEORDER for additional usage instructions.

Examples

Example 1
EXTFILE dirdat/datafile

Example 2
EXTFILE dirdat/extdat, MAXFILES 3, MEGABYTES 2

Example 3
EXTFILE /ggs/dirdat/extdat, FORMAT RELEASE 10.4
**EXTRACT**

**Valid For**

Extract

**Description**

Use the EXTRACT parameter to specify an Extract group for online (continuous) change synchronization. This parameter links the current run with previous runs, so that data continuity is maintained between source and target tables. Unless stopped by a user, Extract runs continuously and maintains checkpoints in the data source and trail to ensure data integrity and fault tolerance throughout planned or unplanned process termination, system outages, or network failure. EXTRACT must be the first entry in the parameter file.

For more information about implementing change synchronization, see the *Administering Oracle GoldenGate for Windows and UNIX*.

**Default**

None

**Syntax**

```
EXTRACT group_name
```

*group_name*

The group name as defined with the ADD EXTRACT command.

**Example**

The following specifies an Extract group named finance.

```
EXTRACT finance
```
EXTTRAIL

Valid For

Extract and Replicat

Description

Use the EXTTRAIL parameter to specify a trail on the local system that was created with the ADD EXTTRAIL command. The trail is read by a data pump Extract group or by a Replicat group on the local system.

EXTTRAIL must precede all associated TABLE statements. Multiple EXTTRAIL statements can be used to define different trails.

Do not use EXTTRAIL for an Extract that is configured in PASSIVE mode. See Administering Oracle GoldenGate for Windows and UNIX for more information about PASSIVE mode, an Oracle GoldenGate security feature.

You can encrypt the data in this trail by using the ENCRYPTTRAIL parameter. See "ENCRYPTTRAIL | NOENCRYPTTRAIL" on page 3-119 for more information.

Default

None

Syntax

EXTTRAIL file_name
[. FORMAT RELEASE major.minor]
[, TRAILBYTEORDER {BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN}]

file_name
The relative or fully qualified name of the trail. Use a maximum of two characters for the name. As trail files are aged, a six-character sequence number will be added to this name, for example /ogg/dirdat/rt000001.

FORMAT RELEASE major.minor
Specifies the metadata format of the data that is sent by Extract to a trail, a file, or (if a remote task) to another process. The metadata tells the reader process whether the data records are of a version that it supports. The metadata format depends on the version of the Oracle GoldenGate process. Older Oracle GoldenGate versions contain different metadata than newer ones.

- FORMAT is a required keyword.

- RELEASE specifies an Oracle GoldenGate release version. major is the major version number, and minor is the minor version number. The x.x must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate x.x version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.)

The release version is programmatically mapped back to an appropriate internal compatibility level. The default is the current version of the process that writes to this trail. Note that RELEASE versions earlier than 12.1 do not support three-part object names.
There is a dependency between FORMAT and the RECOVERYOPTIONS parameter. When RECOVERYOPTIONS is set to APPENDMODE, FORMAT must be set to RELEASE 10.0 or greater. When RECOVERYOPTIONS is set to OVERWRITEMODE, FORMAT must be set to RELEASE 9.5 or less. See "RECOVERYOPTIONS" on page 3-224 for more information.

See the Administering Oracle GoldenGate for Windows and UNIX for additional information about Oracle GoldenGate trail file versioning and recovery modes.

TRAILBYTEORDER (BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN)
Sets the byte format of the metadata in the trail records. This parameter does not affect the column data. Valid only for trails that have a FORMAT RELEASE version of at least 12.1. Valid values are BIGENDIAN (big endian), LITTLEENDIAN (little endian), and NATIVEENDIAN (default of the local system). The default is BIGENDIAN. See theGLOBALS version of TRAILBYTEORDER for additional usage instructions.

Examples

Example 1
EXTTRAIL dirdat/ny

Example 2
EXTTRAIL /ggs/dirdat/ex, FORMAT RELEASE 10.4
FETCHOPTIONS

Valid For
Extract

Description
Use the FETCHOPTIONS parameter to control certain aspects of the way that Oracle GoldenGate fetches data in the following circumstances:

- When the transaction record does not contain enough information for Extract to reconstruct an update operation.
- When Oracle GoldenGate must fetch a column value as the result of a FETCHCOLS clause of a TABLE statement.

FETCHOPTIONS is table-specific. One FETCHOPTIONS statement applies for all subsequent TABLE statements until a different FETCHOPTIONS statement is encountered.

Default fetch properties are adequate for most installations.

FETCHOPTIONS is not valid for SQL/MX.

Default
Ignore missing rows and continue processing

Syntax

FETCHOPTIONS
[, FETCHPKUPDATECOLS]
[, INCONSISTENTROW action]
[, MAXFETCHSTATEMENTS number]
[, MISSINGROW action]
[, NOFETCH]
[, SUPPRESSDUPLICATES]
[, USEKEY | NOUSEKEY]
[, USELATESTVERSION | NOUSELATESTVERSION]
[, USESNAPSHOT | NOUSESsnapshot]
[, USEROWID | NOUSEROWID]

FETCHPKUPDATECOLS
Fetches all unavailable columns when a primary key is updated. This option is off by default. When off, column fetching is performed according to other FETCHOPTIONS options that are enabled.

When on, it only takes effect during an update to a primary key column. The results are the same as using FETCHCOLS (*) in the TABLE statement. LOB columns are included in the fetch.

Use this parameter when using HANDLECOLLISIONS. When Replicat detects a missing update, all of the columns will be available to turn the update into an insert.

INCONSISTENTROW action
Indicates that column data was successfully fetched by row ID, but the key did not match. Either the row ID was recycled or a primary key update occurred after this operation (and prior to the fetch).
**FETCHOPTIONS**

*action* can be one of the following:

**ALLOW**
Allow the condition and continue processing.

**IGNORE**
Ignore the condition and continue processing. This is the default.

**REPORT**
Report the condition and contents of the row to the discard file, but continue processing the partial row.

**DISCARD**
Discard the data and do not process the partial row.

**ABEND**
Discard the data and quit processing.

**MAXFETCHSTATEMENTS number**
Controls the maximum allowable number of prepared queries that can be used by Extract to fetch row data from a source database. The fetched data is used when not enough information is available to construct a logical SQL statement from a transaction log record. Queries are prepared and cached as needed. When the value set with **MAXFETCHSTATEMENTS** is reached, the oldest query is replaced by the newest one. The value of this parameter controls the number of open cursors maintained by Extract for fetch queries only. Additional cursors may be used by Extract for other purposes, such as those required for stored procedures. This parameter is only valid for Oracle databases. The default is 100 statements. Make certain that the database can support the number of cursors specified, plus cursors used by other applications and processes.

For Informix Extracts with multiple databases, you must add **FETCHOPTIONS MAXFETCHSTATEMENTS 1** to your Extract parameter file. This does cause slight performance degradation for the capture process. This is not necessary for a single database Extract.

**MISSINGROW action**
Provides a response when Oracle GoldenGate cannot locate a row to be fetched, causing only part of the row (the changed values) to be available for processing. Typically a row cannot be located because it was deleted between the time the change record was created and when the fetch was triggered, or because the row image required was older than the undo retention specification. *action* can be one of the following:

**ALLOW**
Allow the condition and continue processing. This is the default.

**IGNORE**
Ignore the condition and continue processing.

**REPORT**
Report the condition and contents of the row to the discard file, but continue processing the partial row.

**DISCARD**
Discard the data and do not process the partial row.
ABEND
Discard the data and quit processing.

NOFETCH
Prevents Extract from fetching the column from the database. Extract writes the record to the trail, but inserts a token indicating that the column is missing.

SUPPRESSDUPicates
Valid for Oracle. Avoids target tablespaces becoming overly large when updates are made on LOB columns. For example, after replication a source tablespace of 232MB becomes a target tablespace of 7.52GB.

USEKEY | NOUSEKEY
Determines whether or not Oracle GoldenGate uses the primary key to locate the row to be fetched.

If both USEKEY and USEROWID are specified, ROWID takes priority for faster access to the record. USEROWID is the default.

USELATESTVERSION | NOUSELATESTVERSION
Valid for Oracle. Use with USESNAPSHOT. The default, USELATESTVERSION, directs Extract to fetch data from the source table if it cannot fetch from the undo tablespace. NOUSELATESTVERSION directs Extract to ignore the condition if the snapshot fetch fails, and continue processing.

To provide an alternate action if a snapshot fetch does not succeed, use the MISSINGROW option.

USESNAPSHOT | NOUSESNAPSHOT
Valid for Oracle. The default, USESNAPSHOT, causes Extract to use the Oracle Flashback mechanism to fetch the correct snapshot of data that is needed to reconstruct certain operations that cannot be fully captured from the redo record. NOUSESNAPSHOT causes Extract to fetch the needed data from the source table instead of the flashback logs.

USEROWID | NOUSEROWID
Valid for Oracle. Determines whether or not Oracle GoldenGate uses the row ID to locate the row to be fetched.

If both USEKEY and USEROWID are specified, ROWID takes priority for faster access to the record. USEROWID is the default.

Examples

Example 1
The following directs Extract to fetch data by using Flashback Query and to ignore the condition and continue processing the record if the fetch fails.

FETCHOPTIONS USESNAPSHOT, NOUSELATESTVERSION

Example 2
MAXFETCHSTATEMENTS 150

Example 3
The following directs Extract to fetch data by using Flashback Query and causes Extract to abend if the data is not available.

FETCHOPTIONS USESNAPSHOT, NOUSELATESTVERSION, MISSINGROW ABEND
FILTERDUPS | NOFILTERDUPS

Valid For

Replicat

Description

Use the FILTERDUPS and NOFILTERDUPS parameters to handle anomalies that can occur on a NonStop system when an application performs multiple operations on the same record within the same transaction. This type of transaction can cause out-of-order records in the TMF audit trail and will cause Replicat to abend. For example:

- An insert can occur in the audit trail before a delete on the same primary key, even though the source application performed the delete first, followed by the insert (resulting in a duplicate-record error when the insert is performed by Replicat).
- An update can occur in the audit trail before an insert on the same primary key (resulting in a missing-record error when the update is performed by Replicat).

FILTERDUPS prevents Replicat from abending by resolving the conditions as follows:

- In the event of a duplicate insert, Replicat saves the duplicated insert until the end of the transaction. If a delete with the same primary key is subsequently encountered, Replicat performs the delete, then the insert.
- In the event of a missing update, Replicat saves the missing update until the end of the transaction. If an insert with the same primary key is subsequently encountered, Replicat performs the insert, then the update.

IDX hospital applications and some BASE24 bank applications are the typical, but not the only, sources of this anomaly. Use FILTERDUPS only if Replicat is abending on duplicate or missing records and you know they were caused by out-of-order transactions originating on a NonStop system. The Logdump utility can be used to diagnose this condition.

FILTERDUPS and NOFILTERDUPS can be used as on-off switches for different groups of MAP statements to enable or disable the exception processing as needed.

Default

NOFILTERDUPS

Syntax

FILTERDUPS | NOFILTERDUPS

Example

This example turns on FILTERDUPS for ORDERS but disables it for any MAP statements that are defined later in the same parameter file.

FILTERDUPS
MAP $DATA1.SQLDAT.ORDERS, TARGET MASTER.ORDERS;
NOFILTERDUPS
**FLUSHSECS | FLUSHCSECS**

**Valid For**

Extract

**Description**

Use the `FLUSHSECS` and `FLUSHCSECS` parameters to control when Oracle GoldenGate flushes the Extract memory buffer. When sending data to remote systems, Extract buffers data to optimize network performance. The buffer is flushed to the target system when it is full or after the amount of time specified with `FLUSHSECS` or `FLUSHCSECS`. Data changes are not available to the target users until the buffer is flushed and the data is posted. To control the size of the buffer until the buffer is flushed, use the `TCPBUFSIZE` option of `RMTHOST`. See "RMTHOST" on page 3-249 for more information.

Increasing the value of `FLUSHSECS` or `FLUSHCSECS` could result in slightly more efficient use of the network, but it could increase the latency of the target data if activity on the source system is low and the buffer does not fill up. When source tables remain busy, `FLUSHSECS` and `FLUSHCSECS` have little effect.

This parameter cannot be set to zero (0).

**Default**

The minimum is 1 second; the maximum is 60 seconds.

**Syntax**

```
FLUSHSECS  seconds | FLUSHCSECS  centiseconds
```

- `seconds`
  The delay, in seconds, before flushing the buffer.

- `centiseconds`
  The delay, in centiseconds, before flushing the buffer.

**Example**

```
FLUSHSECS  80
```
FORMATASCII

Valid For

Extract

Description

Use the FORMATASCII parameter to output data in external ASCII format instead of the default Oracle GoldenGate canonical format. Using FORMATASCII, you can format output that is compatible with most database load utilities and other programs that require ASCII input. This parameter is required by the file-to-database-utility initial load method.

A FORMATASCII statement affects all extract files or trails that are listed after it in the parameter file. The relative order of the statements in the parameter file is important. If listed after a file or trail specification, FORMATASCII will not take effect.

Limitations

- Do not use FORMATASCII if the data will be processed by the Replicat process. Replicat expects the default canonical format.
- Do not use FORMATASCII if FORMATSQL or FORMATXML is being used.
- Do not use FORMATASCII if the data contains LOBs.
- Do not use FORMATASCII if Extract is connected to a multi-byte DB2 subsystem.
- Do not use FORMATASCII if Oracle GoldenGate DDL support is active.
- Do not use FORMATASCII in pass-through mode in a data pump because there is no table metadata available to generate trail output in the specified form.

Default Output

Database object names, such as table and column names, and CHAR and VARCHAR data are written in the default character set of the operating system.

Without specifying any parameter options, FORMATASCII generates records in the following format.

Line 1 contains the following tab-delimited list:

- The operation-type indicator: I, D, U, V (insert, delete, update, compressed update).
- A before or after image indicator: B or A.
- The table name in the character set of the operating system.
- A column name, column value, column name, column value, and so forth.
- A newline character (starts a new line).

Line 2 contains the following tab-delimited begin-transaction record:

- The begin transaction indicator, B.
- The timestamp at which the transaction committed.
- The sequence number of the transaction log in which the commit was found.
- The relative byte address (RBA) of the commit record within the transaction log.
Line 3 contains the following tab-delimited commit record:

- The commit character C.
- A newline character.

Every record in a source transaction is contained between the begin and commit indicators. Each combination of commit timestamp and RBA is unique.

**Custom Output**

You can customize the output format with optional arguments.

**Default**

See "Default Output" on page 3-136 for specific defaults.

**Syntax**

```
FORMATASCII [, option] [, ...]
```

`option` can be one of the following:

**BCP**

Formats the output for compatibility with SQL Server’s BCP, DTS, or SQL Server Integration Services (SSIS) bulk-load utility.

**DATE | TIME | TS**

Outputs one of the following:

- DATE outputs the date (year to day).
- TIME outputs the time (year to second).
- TS outputs the transaction timestamp (year to fraction).

**CHARSET set**

(Oracle SQL*Loader) Specifies the encoding of ASCII characters in Oracle NCHAR columns. Valid value is UTF8.

CHARSET allows the load to include character-length semantics when the source table contains NCHAR data and variable-length characters set to UTF-8.

---

**Note:** If both NCHAR and CHAR columns contain 8-bit ASCII characters, the generated file will contain a mix of operating system-native 8-bit ASCII character coding and UTF-8 coding, and the load will not succeed.

**DELIMITER delimiter**

An alternative delimiter character.

Valid values:

- TAB (delimit with tabs). This is the default.
- A character enclosed within single quotes, for example, ‘/’.

**EXTRACOLS number**

Includes placeholders for additional columns at the end of each record. Use this option when a target table has more columns than the source table.
NAMES | NONAMES
Includes or excludes column names as part of the output. For updates where only the changed values are present, column names are included unless you also specify the PLACEHOLDERS option.

NOHDRFIELDS [IND], [OP]
Suppresses output as follows:

**NOHDRFIELDS**
Without options, suppresses everything except the data values themselves.

**IND**
Suppresses everything except the before or after indicator (B or A) and the data values.

**OP**
Suppresses everything except the operation-type indicator (I, D, U, V) and the data values.

**NOQUOTE**
Excludes quotation marks from character data. Without NOQUOTE, characters are enclosed within single-quotes.

**NOTRANSTMTS**
Excludes transaction information.

**NULLISSPACE**
Outputs null columns as empty columns. Without NULLISSPACE, null columns are output as the word NULL.

**PLACEHOLDERS**
Outputs a placeholder for missing columns. For example, if the second and fourth columns are missing in a four-column table, the following output is possible:

'ABC',,,

**SQLLOADER**
Produces a fixed-length, ASCII-formatted file that is compatible with the Oracle SQL*Loader utility or the IBM Load Utility program.

**Examples**

The following examples are based on a source table named test.customer and a sample transaction. The examples show how various FORMATASCII options configure the output.

**Table test.customer:**

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CUSTNAME</td>
<td>CHAR(10)</td>
<td>Primary key</td>
</tr>
<tr>
<td>LOCATION</td>
<td>CHAR(10)</td>
<td></td>
</tr>
<tr>
<td>BALANCE</td>
<td>INTEGER</td>
<td></td>
</tr>
</tbody>
</table>

**Transaction:**

```sql
INSERT INTO CUSTOMER VALUES ('Eric', 'San Fran', 550);
UPDATE CUSTOMER SET BALANCE = 100 WHERE CUSTNAME = 'Eric';
COMMIT;
```
Example 1
FORMATASCII without options produces the following:
B,2011-01-21:14:09:46.421335,8,1873474,
I,A,TEST.CUSTOMER,CUSTNAME,'Eric',LOCATION,
'San Fran',BALANCE,550,
V,A,TEST.CUSTOMER,CUSTNAME,'Eric',BALANCE,100,
C,

Example 2
FORMATASCII, NONAMES, DELIMITER '|' produces the following:
B|2011-01-21:14:09:46.421335|8|1873474|
I|A|CUSTOMER|'Eric'|'San Fran'|550|
V|A|CUSTOMER|CUSTNAME|'Eric'|BALANCE|100|
C|

The last record returns column names for the CUSTNAME and BALANCE columns because
the record only contains values for columns that were updated, and PLACEHOLDERS was
not used.

Example 3
FORMATASCII, NOHDRFIELDS, OP, TS, NONAMES, NOQUOTE produces the following:
I,CUSTOMER,2011-01-21:14:09:46.421335,Eric,San Fran,550,
V,CUSTOMER,2011-01-21:14:09:46.421335,Eric,,100,

The absence of a value for the second column is indicated by two consecutive commas.
**FORMATSQ**

**Valid For**

Extract

**Description**

Use the `FORMATSQ` parameter to output data in external SQL format, instead of the default Oracle GoldenGate canonical format. `FORMATSQ` generates SQL statements (INSERT, UPDATE, DELETE) that can be applied to both SQL and Enscribe tables by utilities other than Oracle GoldenGate Replicat.

---

**Note:** Do not use `FORMATSQ` if the data will be processed by the Replicat process. Replicat expects the default canonical format. Do not use `FORMATSQ` if `FORMATASCII` or `FORMATXML` is being used. Do not use `FORMATASCII` if Oracle GoldenGate DDL support is active.

---

A `FORMATSQ` statement affects all extract files or trails defined after it.

Do not use `FORMATSQ` if Extract is connected to a multi-byte DB2 subsystem.

**Limitations**

- Do not use `FORMATSQ` if the data will be processed by the Replicat process. Replicat expects the default canonical format.
- Do not use `FORMATSQ` if `FORMATASCII` or `FORMATXML` is being used.
- Do not use `FORMATSQ` if Oracle GoldenGate DDL support is active.
- Do not use `FORMATSQ` in pass-through mode in a data pump because there is no table metadata available to generate trail output in the specified form.

**Default Output**

Database object names, such as table and column names, and CHAR and VARCHAR data are written in the default character set of the operating system.

Without options, `FORMATSQ` transactions are output as follows, in comma-delimited format:

- The begin-transaction indicator, B.
- The timestamp at which the transaction was committed.
- The sequence number of the transaction log in which the commit was found.
- The relative byte address (RBA) of the commit record within the transaction log.
- The SQL statements.
- The commit indicator, C.
- A newline indicator.

Every record in a transaction is contained between the begin and commit indicators. Each combination of commit timestamp and RBA is unique.
Customized Output
You can customize the output format with optional arguments.

Default
See "Default Output" on page 3-140 for specific defaults.

Syntax
FORMATSQL [option] [, ...]

option can be one of the following:

NONAMES
Omits column names for insert operations, because inserts contain all column names. This option conserves file size.

NOPKUPDATES
Converts UPDATE operations that affect columns in the target primary key to a DELETE followed by an INSERT. By default (without NOPKUPDATES), the output is a standard UPDATE operation.

ORACLE
Formats records for compatibility with Oracle databases by converting date and time columns to a format accepted by SQL*Plus, for example:

TO_DATE('2011-01-01','YYYY-MM-DD')

Example
FORMATSQL ORACLE, NONAMES
**FORMATXML**

**Valid For**

Extract

**Description**

Use the `FORMATXML` parameter to output data in XML format, instead of the default Oracle GoldenGate canonical format. A `FORMATXML` statement affects all extract files or trails that are defined after it. By default, the XML is output in the character set of the local operating system.

By default, XML stored as CLOB or BLOB is output up to 4000 bytes. To include larger XML stored as BLOB or CLOB, use the `ENCODING` option.

XML stored as CLOB is always output in a `CDATA` section regardless of its size. This is to avoid the overhead of converting reserved characters such as `<`, `>`, and `&` to the appropriate XML representation.

Binary data including BLOB are encoded as Base64, which represents binary data in an ASCII string format and allows output to XML.

The XML, the database object names, such as table and column names, and `CHAR` and `VARCHAR` data are written in the default character set of the operating system unless the `ENCODING` option is used to output in UTF-8.

**Limitations**

- Do not use `FORMATXML` if the data will be processed by the Replicat process. Replicat expects the default canonical format. Do not use `FORMATXML` if `FORMATASCII` or `FORMATSQL` is being used.
- Do not use `FORMATXML` if Extract is connected to a multi-byte DB2 subsystem.
- Do not use `FORMATXML` if Oracle GoldenGate DDL support is active.
- Do not use `FORMATXML` in pass-through mode in a data pump because there is no table metadata available to generate trail output in the specified form.

**Default**

None

**Syntax**

```
FORMATXML
[ENCODING character_set]
[INLINEPROPERTIES | NOINLINEPROPERTIES]
[TRANS | NOTRANS]
```

**ENCODING UTF-8**

Outputs the full sized XML to the XML file in UTF-8, but does not output headers.

The XML header tag and root node are included in the XML output. The root node is output as `OracleGoldenGateFormatXML`.

Regardless of their size, XML stored as CLOB is output in a `CDATA` section and binary data including BLOB is output to Base64 encoding.
**INLINEPROPERTIES | NOINLINEPROPERTIES**
Controls whether or not properties are included within the XML tag or written separately. **INLINEPROPERTIES** is the default.

**TRANS | NOTRANS**
Controls whether or not transaction boundaries and commit timestamps should be included in the XML output. **TRANS** is the default.

**Example**

```
FORMATXML NOINLINEPROPERTIES, NOTRANS
```
FUNCTIONSTACKSIZE

Valid For

Extract and Replicat

Description

Use the FUNCTIONSTACKSIZE parameter to control the size of the memory stack that is used for processing Oracle GoldenGate column-conversion functions. The memory stack holds arguments supplied to and from an Oracle GoldenGate function. You should not need to use this parameter unless Oracle GoldenGate returns a message indicating that the size of the stack should be increased. The message is similar to:

Not enough stack space. Specify FUNCTIONSTACKSIZE greater than {0,number,0}

This could happen when you are using a very large number of functions or arguments.

The default without FUNCTIONSTACKSIZE is 200 arguments, which optimizes the performance of Oracle GoldenGate and its usage of system memory. Increasing this parameter can adversely affect performance and the use of system memory.

When setting FUNCTIONSTACKSIZE for a coordinated Replicat, take into account that the specified value is applied to each thread in the configuration, not as an aggregate threshold for Replicat as a whole. For example, if FUNCTIONSTACKSIZE 400 is specified, it is possible for each thread to have 399 arguments without any warning or error from Replicat.

FUNCTIONSTACKSIZE must appear in the parameter file before any parameters that include functions are listed. FUNCTIONSTACKSIZE is a global parameter. It affects all clauses in a parameter file.

Default

200 arguments

Syntax

FUNCTIONSTACKSIZE number

number

A value between 0 and 5000 that denotes the number of function arguments to allow in a parameter clause.

Example

FUNCTIONSTACKSIZE 300
GENLOADFILES

Valid For

Replicat

Description

Use the GENLOADFILES parameter when using the file-to-database-utility initial load method to generate run and control files that are compatible with:

- Oracle's SQL*Loader utility
- Microsoft's BCP, DTS, or SQL Server Integration Services (SSIS) utility
- IBM's Load Utility (LOADUTIL).

A run file and a control file are generated for each MAP statement in the Replicat parameter file. Replicat stops after generating the control and run files and does not process data.

Use the run and control files with a data file that contains the data to be loaded into the target. To generate the data file, use the FORMATASCII parameter in the Extract parameter file. Use the SQLLOADER option of FORMATASCII for the Oracle and DB2 for z/OS utilities and use the BCP option for the Microsoft utility.

FORMATASCII outputs the table data to an Oracle GoldenGate trail or file in external ASCII format, which is compatible with the load utility. You can generate multiple data files by specifying multiple files.

Note: For IBM's Load Utility, you will need to specify the -E and -d defs_file Collector parameters with the PARAMS option of the RMTHOST parameter. These parameters are necessary to convert ASCII to EBCDIC and to specify the source-definitions file.

By default, GENLOADFILES creates the following file names:

- The SQL*Loader run file is named source_table.run, and the control file is named source_table.ctl, where source_table is the name of a source table specified in the MAP statement.
- The BCP/DTS/SSIS run file is named target_table.bat, and the control file is named target_table.fmt, where target_table is the name of a target table specified in the MAP statement.
- The Load Utility run file is named target_table.run, and the control file is named target_table.ctl, where target_table is the name of a target table specified in the MAP statement.

Control Files

The control file contains load parameters that are generated based on a template. Oracle GoldenGate provides default templates for SQL*Loader, BCP/DTS/SSIS, and Load Utility. You can modify the templates as needed to change the load rules, or you can create new templates.

The following are examples of the Oracle GoldenGate templates, which contain placeholders for the target tables, the data file(s) produced by FORMATASCII, and other
run parameters. Oracle GoldenGate replaces the placeholders with values based on parameters specified in the Replicat parameter file.

**Example 3–1  SQL*Loader Template sqlldr.tpl**

```
# File Names
controlfile ?target.ctl
runfile     ?target.run
#
# Run File Template
sqlldr userid=?pw control=?target log=?target direct=true
#
# Control File Template
unrecoverable
load data
infile ?source.dat
truncate
into table ?target
```

**Example 3–2  BCP/DTS/SSIS Template bcpfmt.tpl**

```
# Run File Template
# Substitute your database name for db
#
# Control File Template
# The value below must specify the BCP version, not the Sybase Adaptive Server or Microsoft SQL Server version. "bcp -v" can be used to determine the correct version number.
12.0
```

**Example 3–3  Load Utility Template db2cntl.tpl**

```
# File Names
controlfile ?target.ctl
runfile     ?target.run
#
# Run File Template
odb2 load
#
# Control File Template
LOAD REPLACE INTO TABLE ?target
```

**Run Files**

The run files contain the input parameters for starting the load. To execute the files, issue one of the following commands.

- Execute the SQL*Loader run file from the UNIX command shell.
  
  `% table.run`

- Execute the BCP run file from the DOS shell.
  
  `> table.bat`

- Execute the Load Utility run file with a JCL script to load the data to the DB2 for z/OS table. Add other environment-related parameters to the job script as needed.
Note: A setting of DYNAMIC for the WILDCARDRESOLVE parameter is not compatible with the GENLOADFILES parameter. Oracle GoldenGate defaults to IMMEDIATE when GENLOADFILES is specified.

Note that Oracle GoldenGate does not support multi-byte characters when the operating system and database character set are different, or when fixed length output format is used.

For step-by-step instructions on configuring Oracle GoldenGate to output the load files and performing the initial load, see the Administering Oracle GoldenGate for Windows and UNIX.

**Default**

None

**Syntax**

```plaintext
GENLOADFILES [template_file]
[CHARSET value]
```

*template_file*

The fully qualified name of the template file. The default template file is `sqlldr.tpl` for SQL*Loader, `bcpfmt.tpl` for BCP, DTS, or SSIS, and `db2cnt1.tpl` for DB2 on z/OS, all located in the Oracle GoldenGate home directory.

*CHARSET set*

(Oracle SQL*Loader) Specifies the encoding of ASCII characters in Oracle NCHAR columns. Valid value is `UTF8`. Required if using CHARSET option of FORMATASCII.

CHARSET allows the load to include character-length semantics when the source table contains NCHAR data and variable-length characters set to UTF-8. Currently, Oracle SQL*Loader uses byte-length semantics and is not compatible with character-length semantics.

**Note:** If both NCHAR and CHAR columns contain 8-bit ASCII characters, the generated file will contain a mix of operating system-native 8-bit ASCII character coding and UTF-8 coding, and the load will not succeed.

**Example**

```plaintext
GENLOADFILES sqlldr.tpl
```
GETAPPLOPS | IGNOREAPPLOPS

Valid For

Extract (Not valid for Informix.)

Description

Use the GETAPPLOPS or IGNOREAPPLOPS parameter to capture or ignore DML operations produced by any application except the local Replicat. By default, application data is captured.

These parameters are useful in conjunction with the GETREPLICATES and IGNOREREPLICATES parameters for the following:

- To separate data operations performed by a local Replicat from those performed by the business applications configured for Oracle GoldenGate extraction. Use IGNOREAPPLOPS and GETREPLICATES for one trail or file to contain just the Replicat operations, and use GETAPPLOPS and IGNOREREPLICATES for another trail or file to contain just the operations of the business applications.
- As part of a cascading configuration, where changes applied by Replicat locally must be captured by a local Extract to be propagated to another system. In this case, IGNOREAPPLOPS and GETREPLICATES would be used.
- As part of a loop detection scheme when using bidirectional replication. The default combination of GETAPPLOPS and IGNOREREPLICATES causes Extract to capture application data while ignoring Replicat operations posted to the same database objects. In addition to using these parameters, Extract must be configured to identify Replicat transactions.

See "GETREPLICATES | IGNOREREPLICATES" on page 3-152 for more information.

Using GETAPPLOPS for Oracle Sequences

GETAPPLOPS must be enabled to capture sequences that are replicated by Replicat. Replicat issues sequence updates in an autonomous transaction, so they are not reflected in the trace table. The sequence update appears as if it is an application operation.

Using GETAPPLEOPS for DDL Operations

See "DDLOPTIONS" on page 3-88 for information on to use GETAPPLOPS or IGNOREAPPLOPS functionality for DDL operations.

For more information about configuring bidirectional replication, see the Administering Oracle GoldenGate for Windows and UNIX.

Default

GETAPPLOPS

Syntax

GETAPPLOPS | IGNOREAPPLOPS
GETDELETES | IGNOREDELETES

Valid For

Extract and Replicat

Description

Use the GETDELETES and IGNOREDELETES parameters to control whether or not Oracle GoldenGate processes DELETE operations. These parameters are table-specific. One parameter remains in effect for all subsequent TABLE or MAP statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the GETDELETES threads in one set of MAP statements, and specify the IGNOREDELETES threads in a different set of MAP statements.

Default

GETDELETES

Syntax

GETDELETES | IGNOREDELETES

Example

This example shows how you can apply GETDELETES and IGNOREDELETES selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

GETDELETES
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
IGNOREDELETES
MAP sales.loc, TARGET sales.loc, THREAD (3);
GETENV

Valid For

Extract and Replicat

Description

Use the GETENV parameter to view environment variables that were set with the SETENV parameter. The results are printed to screen and the report file. Use one GETENV statement per variable to be retrieved.

For more information about using GETENV for column conversion including examples, see “GETENV” on page 5-20.

Default

None

Syntax

GETENV (environment_variable)

environment_variable

The name of the environment variable.

Example

The following shows GETENV statements and sample return values.

GETENV (ORACLE_HOME)
ORACLE_HOME = /home/oracle/ora9/product

GETENV (ORACLE_SID)
ORACLE_SID = ora9
GETINSERTS | IGNOREINSERTS

Valid For

Extract and Replicat

Description

Use the GETINSERTS and IGNOREINSERTS parameters to control whether or not INSERT operations are processed by Oracle GoldenGate. These parameters are table-specific. One parameter remains in effect for all subsequent TABLE or MAP statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the GETINSERTS threads in one set of MAP statements, and specify the IGNOREINSERTS threads in a different set of MAP statements.

Default

GETINSERTS

Syntax

GETINSERTS | IGNOREINSERTS

Example

This example shows how you can apply GETINSERTS and IGNOREINSERTS selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

GETINSERTS
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
IGNOREINSERTS
MAP sales.loc, TARGET sales.loc, THREAD (3);
GETREPLICATES | IGNOREREPLICATES

Valid For

Extract

Description

Use the GETREPLICATES and IGNOREREPLICATES parameters to control whether or not DML transactions issued by Replicat are captured or ignored by an Extract process that is processing the same tables on the same system.

These parameters are not valid for Teradata or Informix.

Ignoring Replicat Transactions

By default, Extract uses a combination of IGNOREREPLICATES and GETAPPLOPS. In this configuration, Extract captures all application data that is configured for synchronization by Oracle GoldenGate, and it ignores all Replicat operations. In a bi-directional configuration, this prevents the data that Replicat applies from looping back to the original system, which would cause duplicate-record errors.

Capturing Replicat Transactions

Use GETREPLICATES with IGNOREAPPLOPS in a cascading configuration to enable replicated data to be captured again by Extract on an intermediary system so that it can be replicated to the final target. For example, if database A replicates to database B, and database B replicates to database C, you would use GETREPLICATES for the Extract on database B.

Note: Even with GETREPLICATES in effect, however, you still can exclude specific replicated data from being captured by using a WHERE or FILTER clause in a TABLE or MAP statement.

Using GETREPLICATES and IGNOREREPLICATES with Oracle

The GETREPLICATES and IGNOREREPLICATES parameters should not be used if you are not using a trace table (the TRACETABLE parameter). By default, Extract captures all transactions including transactions committed by Replicat. If you want to ignore the Replicat transactions, you should use the TRANLOGOPTIONS EXCLUDEUSER parameter. You can also use this to ignore transactions by any specific user in addition to Replicat’s user.

If you are using the TRACETABLE parameter or have the default trace table, GGS_TRACE, created without explicitly using TRACETABLE, then Extract automatically ignores any transaction that has a TRACETABLE update in it by default. If you want to capture the Replicat committed transactions, you have to specify GETREPLICATES. In this case, Oracle does not recommend that you use it with TRANLOGOPTIONS EXCLUDUSER because Replicat will have unpredictable behavior in transaction filtering.

Default

IGNOREREPLICATES

Syntax

GETREPLICATES | IGNOREREPLICATES
GETTRUNCATES | IGNORETRUNCATES

Valid For

Extract and Replicat

Description

Use the GETTRUNCATES and IGNORETRUNCATES parameters to control whether or not Oracle GoldenGate processes table truncate operations. By default, truncate operations are not captured from the source or replicated to the target.

GETTRUNCATES and IGNORETRUNCATES are table-specific. One parameter remains in effect for all subsequent TABLE or MAP statements, until the other parameter is encountered.

In a coordinated Replicat configuration, truncates are always processed by the thread that is responsible for barrier transactions.

Supported Databases

- GETTRUNCATES and IGNORETRUNCATES are not supported for Teradata.
- GETTRUNCATES and IGNORETRUNCATES are supported by Extract for Oracle and Sybase.
- GETTRUNCATES and IGNORETRUNCATES are supported by Replicat for Oracle, SQL Server, Sybase, DB2 LUW, DB2 z/OS, MySQL, SQL/MX, and other ODBC targets that support the TRUNCATE command.

Note: It is not possible to ignore TRUNCATES during capture from a DB2 on z/OS database. By default, TRUNCATES are always captured from a DB2 on z/OS source, but they can be ignored by Replicat if IGNORETRUNCATES is used in the Replicat parameter file.

DB2 LUW Limitations

- DB2 LUW does not support a TRUNCATE command, so Replicat replicates a truncate operation by performing an IMPORT REPLACE from a NULL (blank) file.

Oracle Limitations

- Oracle GoldenGate supports the Oracle TRUNCATE TABLE command, but not TRUNCATE PARTITION. You can replicate TRUNCATE PARTITION as part of the full Oracle GoldenGate DDL replication support.
- The database does not log truncates against an empty table, so those operations are not captured by Oracle GoldenGate. The DDL support of Oracle GoldenGate can be used for this purpose.
- The database does not log truncates for empty partitions, so Oracle GoldenGate cannot reliably process TRUNCATE TABLE when the table contains any empty partitions. Do not use GETTRUNCATES on any partitioned table. Oracle GoldenGate DDL support can be used to capture truncates on tables that might include empty partitions.
Sybase Limitations
For Oracle GoldenGate to support TRUNCATE TABLE for Sybase, all table names must be unique across all schemas within a given database.

Default

IGNORETRUNCATES

Syntax

GETTRUNCATES | IGNORETRUNCATES
GETUPDATEAFTERS | IGNOREUPDATEAFTERS

Valid For

Extract and Replicat

Description

Use the GETUPDATEAFTERS and IGNOREUPDATEAFTERS parameters to control whether or not the after images of columns in UPDATE operations are included in the records processed by Oracle GoldenGate. After images contain the results of the UPDATE.

These parameters are table-specific. One parameter remains in effect for all subsequent TABLE or MAP statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the GETUPDATEAFTERS threads in one set of MAP statements, and specify the IGNOREUPDATEAFTERS threads in a different set of MAP statements.

Default

GETUPDATEAFTERS

Syntax

GETUPDATEAFTERS | IGNOREUPDATEAFTERS

Example

This example shows how you can apply GETUPDATEAFTERS and IGNOREUPDATEAFTERS selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

GETUPDATEAFTERS
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
IGNOREUPDATEAFTERS
MAP sales.loc, TARGET sales.loc, THREAD (3);
Valid For

Extract and Replicat

Description

Use the `GETUPDATEBEFORES` and `IGNOREUPDATEBEFORES` parameters to control whether or not the before images of columns in `UPDATE` operations are included in the records that are processed by Oracle GoldenGate. Before images contain column details that existed before a row was updated. Use the `GETUPDATEBEFORES` parameter as follows:

- in the Extract parameter file to extract before images from the data source.
- in the Replicat parameter file to include before images in a Replicat operation.

You can compare before images with after images to identify the net results of a transaction or perform other delta calculations. For example, if a `BALANCE` field is $100 before an update and $120 afterward, a comparison would show the difference of $20. You can use the column-conversion functions of Oracle GoldenGate to perform the comparisons and calculations.

To reference before images in the parameter file, use the `@BEFORE` conversion function. For example:

```sql
COLMAP (previous = @BEFORE (balance))
```

`GETUPDATEBEFORES` is required when using the Conflict Detection and Resolution (CDR) feature for a Oracle database on any of the platforms that are supported by Oracle GoldenGate. See *Administering Oracle GoldenGate for Windows and UNIX* for more information about CDR.

The `GETUPDATEBEFORES` and `IGNOREUPDATEBEFORES` parameters are table-specific. One parameter remains in effect for all subsequent `TABLE` or `MAP` statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between `MAP` statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the `GETUPDATEBEFORES` threads in one set of `MAP` statements, and specify the `IGNOREUPDATEBEFORES` threads in a different set of `MAP` statements.

Default

`IGNOREUPDATEBEFORES`

Syntax

`GETUPDATEBEFORES | IGNOREUPDATEBEFORES`

Example

This example shows how you can apply `GETUPDATEBEFORES` and `IGNOREUPDATEBEFORES` selectively to different `MAP` statements, each of which represents a different thread of a coordinated Replicat.

```sql
GETUPDATEBEFORES
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
IGNOREUPDATEBEFORES
```
MAP sales.loc, TARGET sales.loc, THREAD (3);
GETUPDATES | IGNOREUPDATES

Valid For
Extract and Replicat

Description
Use the GETUPDATES and IGNOREUPDATES parameters to control whether or not Oracle GoldenGate processes UPDATE operations. These parameters are table-specific. One parameter remains in effect for all subsequent TABLE or MAP statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the GETUPDATES threads in one set of MAP statements, and specify the IGNOREUPDATES threads in a different set of MAP statements.

Default
GETUPDATES

Syntax
GETUPDATES | IGNOREUPDATES

Example
This example shows how you can apply GETUPDATES and IGNOREUPDATES selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

GETUPDATES
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
IGNOREUPDATES
MAP sales.loc, TARGET sales.loc, THREAD (3);
GGSCHEMA

Valid For

GLOBALS

Description

Use the `GGSCHEMA` parameter to specify the name of the schema that contains the database objects that are owned by Oracle GoldenGate, such as those that support DDL replication for trigger based replication. This parameter is valid for the Oracle database.

See *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about the Oracle GoldenGate database objects.

Default

None

Syntax

`GGSCHEMA [container.]schema_name`

`[container.]schema_name`
The fully qualified name of the DDL schema. Use the full three-part name if the schema is within an Oracle container database.
GROUPTRANSOPS

Valid For

Replicat

Description

Use the GROUPTRANSOPS parameter to control the number of SQL operations that are contained in a Replicat transaction when operating in its normal mode (non-BATCHSQL). Increasing the number of operations in a Replicat transaction improves the performance of Oracle GoldenGate by:

- Reducing the number of transactions executed by Replicat.
- Reducing I/O activity to the checkpoint file and the checkpoint table, if used. Replicat issues a checkpoint whenever it applies a transaction to the target, in addition to its scheduled checkpoints.

Replicat accumulates operations from source transactions, in transaction order, and applies them as a group within one transaction on the target. GROUPTRANSOPS sets a minimum value rather than an absolute value, to avoid splitting apart source transactions. Replicat waits until it receives all operations from the last source transaction in the group before applying the target transaction.

For example, if transaction 1 contains 200 operations, and transaction 2 contains 400 operations, and transaction 3 contains 500 operations, the Replicat transaction contains all 1,100 operations even though GROUPTRANSOPS is set to the default of 1,000. Conversely, Replicat might apply a transaction before reaching the value set by GROUPTRANSOPS if there is no more data in the trail to process.

<table>
<thead>
<tr>
<th>Source Transactions (assumes same table and column list)</th>
<th>Replicat transaction in normal (GROUPTRANSOPS) mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Transaction 1:</td>
<td>Transaction:</td>
</tr>
<tr>
<td>INSERT</td>
<td>INSERT</td>
</tr>
<tr>
<td>DELETE</td>
<td>DELETE</td>
</tr>
<tr>
<td>Transaction 2:</td>
<td></td>
</tr>
<tr>
<td>INSERT</td>
<td>INSERT</td>
</tr>
<tr>
<td>DELETE</td>
<td>DELETE</td>
</tr>
<tr>
<td>Transaction 3:</td>
<td></td>
</tr>
<tr>
<td>INSERT</td>
<td>DELETE</td>
</tr>
<tr>
<td>DELETE</td>
<td></td>
</tr>
</tbody>
</table>

Avoid setting GROUPTRANSOPS to an arbitrarily high number because the difference between source and target transaction boundaries can increase the latency of the target data.

(Oracle only) For an integrated Replicat, GROUPTRANSOPS is effective only when the integrated Replicat parameter PARALLELISM is set to 1.

Default

Nonintegrated Replicat: 1000 operations, Integrated Replicat: 50 operations
Syntax

GROUPTRANSOPS number

define number

The minimum number of operations to be applied in a Replicat transaction. A value of 1 executes the operations within the same transaction boundaries as the source transaction. The value must be at least 1.

Example

GROUPTRANSOPS 2000
HANDLECOLLISIONS | NOHANDLECOLLISIONS

Valid For

Replicat

Description

Use the HANDLECOLLISIONS and NOHANDLECOLLISIONS parameters to control whether or not Replicat tries to resolve duplicate-record and missing-record errors when applying SQL on the target. These errors, called collisions, occur during an initial load, when data from source tables is being loaded to target tables while Oracle GoldenGate is replicating transactional changes that are being made to those tables. When Oracle GoldenGate applies the replicated changes after the load is finished, HANDLECOLLISIONS provides Replicat with error-handling logic for these collisions.

You can use HANDLECOLLISIONS and NOHANDLECOLLISIONS in the following ways:

- You can enable HANDLECOLLISIONS and NOHANDLECOLLISIONS in a global manner by specifying them at the root level of the parameter file. One parameter remains enabled for all subsequent MAP statements in the parameter file, until the opposing parameter is encountered.
- You can enable HANDLECOLLISIONS or NOHANDLECOLLISIONS within a specific MAP parameter to enable or disable error handling only for that source-target mapping.

The preceding methods can be combined. You can specify a global collisions-handling rule and then override that rule with different collisions-handling rules in the MAP statements. A MAP specification always overrides the global specification.

How HANDLECOLLISIONS Works

The following example explains how HANDLECOLLISIONS works:

- When Replicat encounters an update to a column that Oracle GoldenGate is using as a key, the handling is as follows:
  - If the row with the old key is not found in the target, the change record in the trail is converted to an insert.
  - If a row with the new key exists in the target, Replicat deletes the row that has the old key (it would not exist if the update had executed successfully), and then the row with the new key is updated as an overlay where the trail values replace the current values.

  This logic requires all of the columns in the table (not just the ones that changed) to be logged to the transaction log, either by default or by force, such as by using the COLS option of ADD TRANDATA for an Oracle database. See “Possible Solutions to Avoid Missing Column Values” on page 3-163 for more information.

- When Replicat encounters a duplicate-record error, the static record that was applied by the initial load is overwritten by the change record in the trail. Overlaying the change is safer from an operational standpoint than ignoring the duplicate-record error.

- When Replicat encounters a missing-record error during an update or delete operation that does not affect a key column, the change record in the trail is discarded. These errors happen when a record is changed on the source system and then the record is deleted before the table data is extracted by the initial-load process. For example:
1. The application updates record A in source table1.
2. Extract extracts the update.
3. The application deletes record A in source table1.
4. Extract extracts the delete.
5. Oracle GoldenGate extracts initial-load data from source table1, without record A.
6. Oracle GoldenGate applies the initial load, without record A.
7. Replicat attempts to apply the update of record A.
8. The database returns a "record missing" error.
9. Replicat attempts to apply the delete of record A.
10. The database returns a "record missing" error.

Disable HANDLECOLLISIONS after the transactional changes captured during the initial load are applied to the target tables, so that Replicat does not automatically handle subsequent errors. Errors generated after initial synchronization indicate an abnormal condition and should be evaluated by someone who can determine how to resolve them. For example, a missing-record error could indicate that a record which exists on the source system was inadvertently deleted from the target system.

You can turn off HANDLECOLLISIONS in the following ways:

- Stop Replicat and remove HANDLECOLLISIONS from the Replicat parameter file (can cause target latency). Alternatively, you can edit the parameter file to add NOHANDLECOLLISIONS before the MAP statements for which you want to disable the error handling.
- While Replicat is running, run GGSCI and then use the SEND REPLICAT command with the NOHANDLECOLLISIONS option for the tables that you want to affect. See "SEND REPLICAT" on page 1-72 for more information.

Note: If using SEND REPLICAT, make certain to remove HANDLECOLLISIONS from the parameter file or add NOHANDLECOLLISIONS parameter before starting another Replicat run, so that HANDLECOLLISIONS does not activate again.

Possible Solutions to Avoid Missing Column Values

When a database does not log all of the column values of a source table by default, there can be errors if the target table has NOT NULL constraints when Replicat attempts to convert a primary-key update to an insert. You can work around this scenario in the following ways:

- Use the NOCOMPRESSUPDATES parameter in the Extract parameter file to send all of the columns of the table to the trail, and configure the database to log all column values. By default, Extract only writes the primary key and the columns that changed to the trail. This is the safest method, because it writes the current values at the time when the operation is performed and eliminates the need for fetching.
- Use the FETCHOPTIONS parameter with the FETCHPKUPDATECOLS option in the Extract parameter file. This configuration causes Extract to fetch unavailable columns when a key column is updated on the source. A fetch is the current value, not necessarily the value at the time of a particular update, so there can be data integrity issues. See "FETCHOPTIONS" on page 3-131 for more information and
additional fetch options to handle unsuccessful fetches.

- To avoid fetches, use HANDLECOLLISIONS with _ALLOWPKMISSINGROWCOLLISIONS to skip the update instead of converting it to an INSERT. This configuration can also cause data integrity issues under certain conditions. See "Preventing Conversion of Key Updates to Inserts" for more information.

### Preparing Conversion of Key Updates to Inserts

In some cases, it is not appropriate to convert an operation that updates a key column to an INSERT if the target row does not exist. In these cases, you can use the _ALLOWPKMISSINGROWCOLLISIONS option to force Replicat to skip the operation, instead of applying it as an insert.

The following example illustrates such a case. This scenario performs an instantiation of Oracle GoldenGate replication, using the default HANDLECOLLISIONS logic, to show what happens if column values are missing when Replicat tries to convert the update to an insert.

**Source and target tables:**

Both tables are named *sample*.

<table>
<thead>
<tr>
<th>f1</th>
<th>f2</th>
<th>f3</th>
<th>f4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10-01-2011 11:30:45</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>10-02-2011 14:15:20</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>10-03-2011 15:12:55</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

- All columns are **NOT NULL**.
- f1 is the primary key.
- f2 is a date field that automatically updates whenever the record is changed.
- KEYCOLS is used in the parameter files to instruct Oracle GoldenGate to use f1 and f2 as the key.
- ADD TRANDATA was issued accordingly, to log column f2. Column f1 is automatically logged because it is a primary key.

**DML sequence of events:**

1. **Start Extract** to capture ongoing transactions.

2. **UPDATE** the table as follows:

   ```sql
   update sample set f3=3 where f1=2;
   ```

   In this operation, column f2 updates automatically with the current date and time. Oracle GoldenGate considers this to be a key update.

   The row now looks like this:

<table>
<thead>
<tr>
<th>f1</th>
<th>f2</th>
<th>f3</th>
<th>f4</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>10-20-2011 08:01:32</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

3. **DELETE** the same row.

   ```sql
   delete sample where f1=2;
   ```

   Now the table contains the following rows:

<table>
<thead>
<tr>
<th>f1</th>
<th>f2</th>
<th>f3</th>
<th>f4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10-01-2011 11:30:45</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>10-03-2011 15:12:55</td>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>
4. Perform an export/import of the source data to the target, using
HANDLECOLLISIONS to handle missing or duplicate rows.

5. The replicated update (update sample, set f3=3 where f1=2) is the first
operation to be applied from the trail by Replicat. It fails because the row was
deleted from the source before the import/export was performed.

6. Replicat converts the UPDATE to an INSERT according to HANDLECOLLISIONS logic for
operations that update a key column (the f2 date-time column).

7. In a case where all of the column values are available in the trail, the new INSERT
succeeds. Moreover, it does not cause inconsistency, even though the row was
deleted on the source, because the replicated delete (delete sample where f1=2)
removes it again. However, in this example, there are two problems:

- Only columns f1 and f2, plus the changed value of f3, are logged. The value
  for f4 is not logged and the value is not available for the insert operation.
- All columns have a NOT NULL constraint.

The missing f4 value causes the INSERT to fail. By using _
ALLOWPKMISSINGROWCOLLISIONS, Replicat skips the UPDATE instead of converting it to
an INSERT. This causes the subsequent DELETE to fail because the row does not exist, so
Replicat skips the DELETE record as part of the default HANDLECOLLISIONS logic. The
data now is consistent with that of the source.

Messages from _ALLOWPKMISSINGROWCOLLISIONS

Because of the risk of data loss associated with _ALLOWPKMISSINGROWCOLLISIONS, a
warning is issued when it is used. The warning is similar to the following text:

Using _ALLOWPKMISSINGROWCOLLISIONS may cause data corruption under certain
conditions.

A warning message also is issued for when an UPDATE to a key does not contain a full
after image for conversion to an insert:

A complete after image is not available in SOURCE.x, at RBA 123, in file
.dirdat\aa000000, while inserting a row into TARGET.x due to a missing target row
for a key update operation. NOCOMPRESSUPDATES or FETCHOPTIONS FETCHPKUPDATECOLS
may be specified in the EXTRACT parameter file to include a complete image for key
update operations.

Getting More Information about Initial Loads

See Administering Oracle GoldenGate for Windows and UNIX for more information about
Oracle GoldenGate initial load methods.

Default

NOHANDLECOLLISIONS

Syntax

HANDLECOLLISIONS | NOHANDLECOLLISIONS [_ALLOWPKMISSINGROWCOLLISIONS]
[THREADS (threadId[, threadId][, ...][, thread_range[, thread_range][, ...]])]

HANDLECOLLISIONS

Enables collision handling.
HANDLECOLLISIONS | NOHANDLECOLLISIONS

ALLOWPKMISSINGROWCOLLISIONS

Use HANDLECOLLISIONS with ALLOWPKMISSINGROWCOLLISIONS to skip primary-key UPDATE operations if the corresponding target row does not exist.

Note: Skipping operations can cause data corruption. See the Description in this topic.

NOHANDLECOLLISIONS

Turns off collision handling.

THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])

Enables HANDLECOLLISIONS for the specified threads. When used in a global HANDLECOLLISIONS statement at the root level of the parameter file, HANDLECOLLISIONS is enabled for the specified threads wherever they are in all MAP statements where . When used in a HANDLECOLLISIONS clause of a MAP statement, HANDLECOLLISIONS is enabled only for that MAP statement.

threadID[, threadID][, ...]

Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

thread_range[, thread_range][, ...]

Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

Examples

Example 1

This example enables HANDLECOLLISIONS for all MAP statements in the parameter file.

HANDLECOLLISIONS
MAP hr.emp, TARGET hr.emp;
MAP hr.job_hist, TARGET hr.job_hist;
MAP hr.dep, TARGET hr.dep;
MAP hr.country, TARGET hr.country;

Example 2

This example enables HANDLECOLLISIONS for some MAP statements while disabling it for others.

HANDLECOLLISIONS
MAP hr.emp, TARGET hr.emp;
MAP hr.job_hist, TARGET hr.job_hist;
NOHANDLECOLLISIONS
MAP hr.dep, TARGET hr.dep;
MAP hr.country, TARGET hr.country;

Example 3

This example shows the basic use of HANDLECOLLISIONS within a MAP statement.

MAP dbo.tcust, TARGET dbo.tcust, HANDLECOLLISIONS;
Example 4
This example shows a combination of global and MAP-level use. The MAP specification overrides the global specification for the specified tables.

HANDLECOLLISIONS
MAP hr.emp, TARGET hr.emp;
MAP hr.job_hist, TARGET hr.job_hist;
MAP hr.dep, TARGET hr.dep, NOHANDLECOLLISIONS;
MAP hr.country, TARGET hr.country, NOHANDLECOLLISIONS;

Example 5
In the following example, HANDLECOLLISIONS is enabled globally for all MAP statements, except for default thread 0 in the first MAP statement and for thread 3 in the second MAP statement.

HANDLECOLLISIONS
MAP fin.*, TARGET fin.*;
MAP sales.*, TARGET sales.*;
MAP orders.*, TARGET orders.*;
MAP scott.cust, TARGET scott.cust, NOHANDLECOLLISIONS;
MAP amy.cust, TARGET amy.cust, THREAD(3), NOHANDLECOLLISIONS;

Example 6
In this example, HANDLECOLLISIONS is enabled globally, but turned off for thread 3. The remaining threads 1, 2, and 4 will handle collisions.

HANDLECOLLISIONS
NOHANDLECOLLISIONS THREAD(3)
MAP scott.employees, TARGET scott.employees, THREADRANGE(1,4, OID);
MAP scott.inventory, TARGET scott.inventory, THREADRANGE(1,4, OID);
MAP scott.cust, TARGET scott.cust, THREADRANGE(1,4, OID);

Example 7
In this example, HANDLECOLLISIONS is enabled globally, then disabled globally for threads 5 through 7. In the first map statement, all threads will handle collisions, since the HANDLECOLLISIONS parameter does not specify a thread or a range. In the second map statement, only threads 4, 8, and 9 will handle collisions, because the global NOHANDLECOLLISIONS applies to threads 5-7.

HANDLECOLLISIONS
NOHANDLECOLLISIONS THREADRANGE(5-7)
MAP scott.cust, TARGET scott.cust, THREADRANGE(4,9, OID), HANDLECOLLISIONS;
MAP scott.offices, TARGET scott.offices, THREADRANGE(4,9, OID);
MAP scott.emp, TARGET scott.emp, THREADRANGE(4,9, OID);
MAP scott.ord, TARGET scott.ord, THREADRANGE(4,9, OID);
MAP acct.*, TARGET acct.*;
MAP admin.*, TARGET admin.*;
**HANDLETPKUPDATE**

**Valid For**

Replicat (nonintegrated mode)

**Description**

Use the `HANDLETPKUPDATE` parameter to prevent constraint errors when an update to a primary key results in a transient duplicate. This is an Oracle parameter for nonintegrated Replicat and is required if the target database is any version earlier than Oracle version 11.2.0.2. For target Oracle databases that are version 11.2.0.2 or later, transient primary-key duplicates are handled automatically without requiring `HANDLETPKUPDATE`. Integrated Replicat handles this issue automatically so it is not necessary to set this parameter.

A transient primary-key duplicate occurs when an update affects the primary keys of multiple rows in a transaction. This kind of statement typically uses a `SET x = x+n` formula or other manipulation that shifts the values so that a new value is the same as an existing one.

The following example illustrates a sequence of value changes that can cause this condition. The example assumes table `ITEM` where the primary key column is named `CODE` and the current key values for the rows in the table are 1, 2, and 3.

```sql
update item set code = 2 where code = 1;
update item set code = 3 where code = 2;
update item set code = 4 where code = 3;
```

In this example, when the first `UPDATE` is applied to the target, there is an error because the primary key value of 2 already exists in the target. The target transaction returns constraint violation errors. By default, Replicat does not detect or handle these violations and abends.

When using `HANDLETPKUPDATE`, create the constraints as `DEFERRABLE INITIALLY IMMEDIATE` on the target tables. If the target constraints cannot be `DEFERRABLE`, Replicat handles the errors according to existing rules specified with the `HANDLECOLLISIONS` and `REPERROR` parameters, or else it abends.

This parameter can be used in a parameter file, and it can be used within a `MAP` statement as follows:

```sql
MAP ggs.equip_account, TARGET ggs.equip_account, HANDLETPKUPDATE;
```

**Default**

Abend on transient primary key updates

**Syntax**

`HANDLETPKUPDATE`
HAVEUDTWITHNCHAR

Valid For

Replicat (Oracle only)

Description

Use the HAVEUDTWITHNCHAR parameter when the source data contains user-defined types that have an NCHAR, NVARCHAR2, or NCLOB attribute. When this data is encountered in the trail, HAVEUDTWITHNCHAR causes Replicat to connect to the Oracle target in AL32UTF8, which is required when a user-defined data type contains one of those attributes.

HAVEUDTWITHNCHAR is not required if the character set of the target is AL32UTF8. However, it is required if only NLS_LANG is set to AL32UTF8 on the target. By default Replicat ignores NLS_LANG and connects to an Oracle database in the native character set of the database. Replicat uses the OCIDString object of the Oracle Call Interface, which does not support NCHAR, NVARCHAR2, or NCLOB attributes, so Replicat must bind them as CHAR. Connecting to the target in AL32UTF8 prevents data loss in this situation.

HAVEUDTWITHNCHAR must be specified before the USERID or USERIDALIAS parameter in the parameter file.

Default

None

Syntax

HAVEUDTWITHNCHAR
INCLUDE

Valid For

Extract and Replicat

Description

Use the INCLUDE parameter to include a macro library in a parameter file. See Administering Oracle GoldenGate for Windows and UNIX for more information about using macros.

Default

None

Syntax

INCLUDE library

library
The relative or full path to library file.

Example

The following example includes macro library mdatelib.mac.

INCLUDE /ggs/dirprm/mdatelib.mac
INSERTALLRECORDS

Valid For

Replicat

Description

Use the INSERTALLRECORDS parameter to keep a record of all operations made to a target record, instead of maintaining just the current version. INSERTALLRECORDS causes Replicat to insert every change that is made to a record as a new record in the database. The initial insert and subsequent updates and deletes are maintained as point-in-time snapshots.

Some cases for using INSERTALLRECORDS are the following:

- To work within an exceptions MAP statement. In an exceptions MAP statement, INSERTALLRECORDS causes the values of operations that generated errors to be inserted as new records in an exceptions table as part of an error-handling strategy.

- To maintain a transaction history. By inserting every change to a specific row as a new record in the database, you can maintain a history of all changes made to that row, instead of maintaining just the current version. Each insert is a point-in-time snapshot that can be queried as needed for auditing purposes. Combining historical data with special transaction information provides a way to create a more useful target reporting database.

INSERTALLRECORDS can be used at the root level of the parameter file to affect all subsequent MAP statements, and it can be used within a MAP statement to affect a specific table or multiple tables specified with a wildcard.

Getting More Information about INSERTALLRECORDS

See Administering Oracle GoldenGate for Windows and UNIX for information about creating a transaction history table.

See Administering Oracle GoldenGate for Windows and UNIX for information about using an exceptions MAP statement.

See "TABLE | MAP" on page 3-305 for MAP syntax.

Default

None

Syntax

INSERTALLRECORDS

Examples

Example 1

This example shows INSERTALLRECORDS at the root level of the parameter file as part of an exceptions handling configuration.

REPLICAT deliv
USERIDALIAS tiger1
ASSUMETARGETDEFS
REPERRO (DEFAULT, EXCEPTION)
MAP ggs.equip_account, TARGET ggs.equip_account2,
COLMAP (USEDEFAULTS);
MAP ggs.equip_account, TARGET ggs.equip_account_exception,
EXCEPTIONONLY,
INSERTALLRECORDS
COLMAP (USEDEFAULTS,
DML_DATE = @DATENOW(),
OPTYPE = @GETENV('LASTERR', 'OPTYPE'),
DBERRNUM = @GETENV('LASTERR', 'DBERRNUM'),
DBERRMSG = @GETENV('LASTERR', 'DBERRMSG'));

Example 2
This example shows INSERTALLRECORDS in a MAP statement.

REPLICAT deliv
USERIDALIAS tiger1
SOURCEDEFS /ggs/dirdef/defs
REPERRO DEFAULT, ABEND
MAP fin.accTAB, TARGET fin.custTAB, INSERTALLRECORDS;
INSERTAPPEND | NOINSERTAPPEND

Valid For
Replicat (nonintegrated mode)

Description
Use the INSERTAPPEND and NOINSERTAPPEND parameters to control whether or not a Replicat operating in nonintegrated mode uses an APPEND hint when it applies INSERT operations (used for array binding) to Oracle target tables. These parameters are valid only for Oracle databases and are only compatible with BATCHSQL mode.

INSERTAPPEND causes Replicat to use the APPEND_VALUES hint when it applies INSERT operations to Oracle target tables. It is appropriate for use as a performance improvement when the replicated transactions are large and contain multiple inserts into the same table. If the transactions are small, using INSERTAPPEND can cause a performance decrease. For more information about when APPEND hints should be used, consult the Oracle documentation.

The BATCHSQL parameter must be used when using INSERTAPPEND. Replicat will abend if BATCHSQL is not used.

These parameters can be used in two ways: When used as standalone parameters at the root of the parameter file, one remains in effect for all subsequent TABLE or MAP statements, until the other is encountered. When used within a MAP statement, they override any standalone INSERTAPPEND or NOINSERTAPPEND entry that precedes the MAP statement.

See “TABLE | MAP” on page 3-305 for more information about the MAP parameter.

Default
NOINSERTAPPEND

Syntax
INSERTAPPEND | NOINSERTAPPEND

Examples

Example 1
The following is part of a Replicat parameter file that shows how INSERTAPPEND is used for all of the tables in the fin schema, except for the inventory table.

BATCHSQL
INSERTAPPEND
MAP fin.*, TARGET fin2.*;
MAPEXCLUDE fin.inventory;
NOINSERTAPPEND
MAP fin.inventory, TARGET fin2.inventory;

Example 2
The following is part of a Replicat parameter file that shows how INSERTAPPEND is used for all of the tables in the MAP statements, except for the inventory table.

BATCHSQL
MAP fin.orders, TARGET fin.orders;
MAP fin.customers, TARGET fin.customers;
MAP fin.inventory, TARGET fin.inventory, NOINSERTAPPEND;
**INSERTDELETES | NOINSERTDELETES**

**Valid For**

Replicat

**Description**

Use the `INSERTDELETES` and `NOINSERTDELETES` parameters to control whether or not Oracle GoldenGate converts source delete operations to insert operations on the target database. The parameters are table-specific. One parameter remains in effect for all subsequent `MAP` statements, until the other parameter is encountered.

When using `INSERTDELETES`, use the `NOCOMPRESSDELETES` parameter so that Extract does not compress deletes.

Because you can selectively enable or disable these parameters between `MAP` statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the `INSERTDELETES` threads in one set of `MAP` statements, and specify the `NOINSERTDELETES` threads in a different set of `MAP` statements.

**Default**

`NOINSERTDELETES`

**Syntax**

`INSERTDELETES | NOINSERTDELETES`

**Example**

This example shows how you can apply `INSERTDELETES` and `NOINSERTDELETES` selectively to different `MAP` statements, each of which represents a different thread of a coordinated Replicat.

`INSERTDELETES`

```
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
```

`NOINSERTDELETES`

```
MAP sales.loc, TARGET sales.loc, THREAD (3);
```
Valid For

Replicat

Description

Use the INSERTMISSINGUPDATES and NOINSERTMISSINGUPDATES parameters to control whether or not Oracle GoldenGate inserts a record based on the source record when the target record does not exist.

INSERTMISSINGUPDATES inserts the missing update but should only be used when the source database logs all column values, whether or not they changed. It can work with a database that uses a compressed form of updates (where only the changed values are logged) if the target database allows NULL to be used for the missing column values.

When the default of NOINSERTMISSINGUPDATES is in effect, a missing record causes an error, and the transaction may abend depending on REERROR settings.

The INSERTMISSINGUPDATES and NOINSERTMISSINGUPDATES parameters are table-specific. One parameter remains in effect for all subsequent MAP statements, until the other parameter is encountered.

Default

NOINSERTMISSINGUPDATES

Syntax

INSERTMISSINGUPDATES | NOINSERTMISSINGUPDATES
INSERTUPDATES | NOINSERTUPDATES

Valid For

Replicat

Description

Use the INSERTUPDATES and NOINSERTUPDATES parameters to control whether or not Oracle GoldenGate converts update operations to insert operations. For updates to be converted to inserts, the database must log all column values either by default or by means of supplemental logging.

The parameters are table-specific. One parameter remains in effect for all subsequent MAP statements, until the other parameter is encountered.

To ensure that updates are not compressed by Extract when using INSERTUPDATES, use the NOCOMPRESSUPDATES parameter.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the INSERTUPDATES threads in one set of MAP statements, and specify the NOINSERTUPDATES threads in a different set of MAP statements.

Default

NOINSERTUPDATES

Syntax

INSERTUPDATES | NOINSERTUPDATES

Example

This example shows how you can apply INSERTUPDATES and NOINSERTUPDATES selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

INSERTUPDATES
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
NOINSERTUPDATES
MAP sales.loc, TARGET sales.loc, THREAD (3);
LAGCRITICAL

Valid For
Manager

Description
Use the LAGCRITICALSECONDS, LAGCRITICALMINUTES, or LAGCRITICALHOURS parameter to specify a lag threshold that is considered critical, and to force a warning message to the error log when the threshold is reached. This parameter affects Extract and Replicat processes on the local system.

Default
Do not report lag information

Syntax
LAGCRITICALSECONDS seconds | LAGCRITICALMINUTES minutes | LAGCRITICALHOURS hours

LAGCRITICALSECONDS seconds
Sets the critical lag threshold in seconds.

LAGCRITICALMINUTES minutes
Sets the critical lag threshold in minutes.

LAGCRITICALHOURS hours
Sets the critical lag threshold in hours.

Example
LAGCRITICALSECONDS 60
LAGINFO

Valid For
Manager

Description
Use the LAGINFOSECONDS, LAGINFOMINUTES, or LAGINFOHOURS parameter to specify a basic lag threshold; if lag exceeds the specified value, Oracle GoldenGate reports lag information to the error log. If the lag exceeds the value specified with the LAGCRITICAL parameter, Manager reports the lag as critical; otherwise, it reports the lag as an informational message. A value of zero (0) forces a message at the frequency specified with the LAGREPORTMINUTES or LAGREPORTHOURS parameter.

Default
Do not report lag information

Syntax
LAGINFOSECONDS seconds | LAGINFOMINUTES minutes | LAGINFOHOURS hours

LAGINFOSECONDS seconds
Sets a basic lag threshold in seconds.

LAGINFOMINUTES minutes
Sets a basic lag threshold in minutes.

LAGINFOHOURS hours
Sets a basic lag threshold in hours.

Example
In this example, Oracle GoldenGate reports lag when it exceeds one hour.
LAGINFOHOURS 1
LAGREPORT

Valid For
Manager

Description
Use the LAGREPORTMINUTES or LAGREPORTHOURS parameter to specify the interval at which Manager checks for Extract and Replicat lag. Use of this parameter also requires the use of the LAGINFO and LAGCRITICAL parameters. If LAGREPORT is not specified, lag is not reported.

If LAGREPORT is used and the value of the CHECKMINUTES parameter is greater than LAGREPORT, then CHECKMINUTES will acquire the value of LAGREPORT.

Default
None

Syntax
LAGREPORTMINUTES minutes | LAGREPORTHOURS hours

LAGREPORTMINUTES minutes
The frequency, in minutes, to check for lag.

LAGREPORTHOURS hours
The frequency, in hours, to check for lag.

Example
LAGREPORTHOURS 1
LIST | NOLIST

Valid For

Extract and Replicat

Description

Use the LIST and NOLIST parameters to control whether or not the macros of a macro library are listed in the report file. Listing can be turned on and off by placing the LIST and NOLIST parameters within the parameter file or within the macro library file. Using NOLIST reduces the size of the report file. For more information about using macros, see the Administering Oracle GoldenGate for Windows and UNIX.

Default

LIST

Syntax

LIST | NOLIST

Example

In the following example, NOLIST excludes the macros in the hugelib macro library from being listed in the report. Using LIST after the INCLUDE statement restores normal listing for subsequent macros.

NOLIST
INCLUDE /ggs/hugelib.mac
LIST
LOBMEMORY

Valid For

Extract and Replicat for DB2 on z/OS and NonStop SQL/MX

Description

Use the `LOBMEMORY` parameter to control the amount of memory and temporary disk space available for caching transactions that contain LOBs. Because Oracle GoldenGate applies only committed transactions to the target database, it requires sufficient system memory to store LOB data until either a commit or rollback indicator is received.

This parameter is for use with a DB2 database on z/OS and for a NonStop SQL/MX database. For all other databases, use the `CACHEMGR` parameter.

About Memory Management with LOBMEMORY

`LOBMEMORY` enables you to tune the cache size of Oracle GoldenGate for LOB transactions and define a temporary location on disk for storing data that exceeds the size of the cache. Options are available for defining the total cache size, the per-transaction memory size, the initial and incremental memory allocation, and disk storage space.

LOB transactions are added to the memory pool specified by `RAM`, and each is flushed to disk when `TRANSRAM` is reached. An initial amount of memory is allocated to each transaction based on `INITTRANSRAM` and is increased by the amount specified by `RAMINCREMENT` as needed, up to the maximum set with `TRANSRAM`. Consequently, the value for `TRANSRAM` should be evenly divisible by the sum of `(INITTRANSRAM + RAMINCREMENT)`.

Default

See option defaults

Syntax

```
LOBMEMORY
[RAM size]
[TRANSRAM size]
[TRANSALLSOURCES size]
[INITTRANSRAM size]
[RAMINCREMENT size]
[DIRECTORY (directory, max_directory_size, max_file_size)]
```

**RAM size**

Specifies the total amount of memory to use for all cached LOB transactions. The default is 200 megabytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

```
GB | MB | KB | G | M | K | gb | mb | kb | g | m | k
```

**TRANSRAM size**

Specifies the total amount of memory to use for a single LOB transaction. The default is 50 megabytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

```
GB | MB | KB | G | M | K | gb | mb | kb | g | m | k
```
TRANSRAM should be evenly divisible by both INITTRANSRAM and RAMINCREMENT for optimal results.

TRANSALLSOURCES size
Specifies the total amount of memory and disk space to use for a single LOB transaction. The default is 50% of total available memory (memory and disk). The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

| GB | MB | KB | G | M | K | gb | mb | kb | g | m | k |

INITTRANSRAM size
Specifies the initial amount of memory to allocate for a LOB transaction. The default is 500 kilobytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

| GB | MB | KB | G | M | K | gb | mb | kb | g | m | k |

RAMINCREMENT size
Specifies the amount of memory to increment when a LOB transaction requires more memory. The default is 500 kilobytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

| GB | MB | KB | G | M | K | gb | mb | kb | g | m | k |

DIRECTORY (directory, max_directory_size, max_file_size)
Specifies temporary disk storage for LOB transaction data when its size exceeds the maximum specified with TRANSRAM. You can specify DIRECTORY more than once.

- directory is the fully qualified name of a directory. The default is the dirtmp sub-directory of the Oracle GoldenGate directory.
- max_directory_size is the maximum size of all files in the directory. The default is 2 gigabytes. If the space specified is not available, then 75% of available disk space is used.
- max_file_size is the maximum size of each file in the directory. The default is 200 megabytes.

Values can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

| GB | MB | KB | G | M | K | gb | mb | kb | g | m | k |

The directory size and file size must be greater than the size of the memory specified with RAM.

The file names use the following format.

- group_blob_00001.mem
- PID_blob_00001.mem

A group name is used for online processes. A system process ID number (PID) is used for one-time runs specified with the SPECIALRUN parameter.

The format for a threaded Extract is similar to the following, depending on the database.

- group_thread #_00001.mem
Examples

Example 1
The following example allows per-transaction memory to be incremented ten times before data is flushed to disk, once for the initial allocation specified with INITTRANSRAM and then nine more times as permitted by RAMINCREMENT.

LOBMEMORY DIRECTORY (c:\test\dirtmp, 3000000000, 300000000), &
RAM 8000K, TRANSRAM 1000K, INITTRANSRAM 100K, RAMINCREMENT 100K

Example 2
The following is the same as the preceding example, but with the addition of a second directory.

LOBMEMORY DIRECTORY (c:\test\dirtmp, 3000000000, 300000000), &
DIRECTORY (c:\test\dirtmp2, 1000000000, 5000000), &
RAM 8000K, TRANSRAM 1000K, INITTRANSRAM 100K, RAMINCREMENT 100K
LOGALLSUPCOLS | NOLOGALLSUPCOLS

Valid For

Extract (Oracle databases only)

Description

Use the LOGALLSUPCOLS and NOLOGALLSUPCOLS parameters to control the writing of supplementally logged columns specified with ADD TRANDATA or ADD SCHEMATRANDATA to the trail.

LOGALLSUPCOLS supports integrated Replicat (for Oracle database) and the Oracle GoldenGate Conflict Detection and Resolution feature (CDR). The supplementally logged columns are a union of the scheduling columns that are required to ensure data integrity across parallel Replicat threads and the conflict detection and resolution (CDR) columns. Scheduling columns are primary key, unique index, and foreign key columns. Including all of these supplementally logged columns satisfies the requirements of both CDR and dependency computation in parallel Replicat processing.

LOGALLSUPCOLS causes Extract to do the following with these supplementally logged columns:

- Automatically includes in the trail record the before image for UPDATE operations.
- Automatically includes in the trail record the before image of all supplementally logged columns for both UPDATE and DELETE operations.

NOLOGALLSUPCOLS is the default and prevents the supplementally logged columns from being written to the trail.

For Extract versions older than 12c, you can use GETUPDATEBEFORES and NOCOMPRESSDELETES parameters to satisfy the same requirement. See GETUPDATEBEFORES | IGNOREUPDATEBEFORES and COMPRESSUPDATES | NOCOMPRESSUPDATES for more information.

LOGALLSUPCOLS | NOLOGALLSUPCOLS takes precedence over the following parameters, if used:

- GETUPDATEBEFORES | IGNOREUPDATEBEFORES
- COMPRESSDELETES | NOCOMPRESSDELETES
- COMPRESSUPDATES | NOCOMPRESSUPDATES for before images, but COMPRESSUPDATES | NOCOMPRESSUPDATES takes precedence over LOGALLSUPCOLS on after images.

Default

NOLOGALLSUPCOLS

Syntax

LOGALLSUPCOLS | NOLOGALLSUPCOLS
Valid For

Extract and Replicat

Description

Use the MACRO parameter to create an Oracle GoldenGate macro. See Administering Oracle GoldenGate for Windows and UNIX for more information about using macros, including how to invoke them properly.

Default

None

Syntax

The following must be used in the order shown:

```plaintext
MACRO #macro_name
PARAMS (#param_name [, ...])
BEGIN
macro_body
END;
```

MACRO

Starts the macro specification.

#

The macro character. Macro and parameter names must begin with a macro character. Anything in the parameter file that begins with the macro character is assumed to be either a macro or a macro parameter.

The default macro character is the pound (#) character, as in the following examples:

```plaintext
MACRO #macro1
PARAMS (#param1, #param2)
```

You can change the macro character with the MACROCHAR parameter.

macro_name

The name of the macro. Macro names must be one word with alphanumeric characters (underscores are allowed) and are not case-sensitive. Each macro name in a parameter file must be unique. Do not use quotes, or else the macro name will be treated as text and ignored.

PARAMS

Starts a parameter clause. A parameters clause is optional. The maximum size and number of parameters is unlimited, assuming sufficient memory is available.

param_name

Describes a parameter to the macro. Parameter names are not case-sensitive. Do not use quotes, or else the parameter name will be treated as text and ignored.

Every parameter used in a macro must be declared in the PARAMS statement, and when the macro is invoked, the invocation must include a value for each parameter.

Example 1 shows a macro that takes parameters.
You can create macros without parameters, such as a macro for frequently used commands. See Example 2.

You can use other macros as parameters. See Example 3.

**BEGIN**

Begins the macro body. Must be specified before the macro body.

**macro_body**

The body of the macro. The size of the macro body is unlimited, assuming sufficient available memory. A macro body can include any of the following types of statements:

- Simple parameter statements, as in:
  ```
  COL1 = COL2
  ```

- Complex statements, as in:
  ```
  COL1 = #val2
  ```

- Invocations of other macros, as in:
  ```
  #colmap(COL1, #sourcecol)
  ```

**END;**

Concludes the macro definition. The semicolon is required to complete the definition.

### Examples

#### Example 1

The following example defines a macro that takes parameters.

```sql
MACRO #make_date
PARAMS (#year, #month, #day)
BEGIN
@DATE('YYYY-MM-DD', 'CC', @IF(#year < 50, 20, 19),
  'YY', #year, 'MM', #month, 'DD', #day)
END;
```

#### Example 2

The following example defines a macro that does not require parameters.

```sql
MACRO #option_defaults
BEGIN
GETINSERTS
GETUPDATES
GETDELETESE
INSERTDELETESE
END;
```

#### Example 3

The following example defines a macro named #assign_date that calls another macro named #make_date.

```sql
MACRO #assign_date
PARAMS (#target_col, #year, #month, #day)
BEGIN
#target_col = #make_date (#year, #month, #day)
END;
```
**MACROCHAR**

**Valid For**

Extract and Replicat

**Description**

Use the MACROCHAR parameter to change the macro character of a macro definition to something other than the # character. You might need to change the macro character when, for example, table names include the # character.

The MACROCHAR parameter can only be used once in the parameter file. Place the MACROCHAR parameter before the first MACRO parameter in the parameter file. Anything in the parameter file that begins with the specified macro character is assumed to be either a macro or a macro parameter. All macro definitions in the parameter file must use the specified character.

See also "MACRO" on page 3-186.

See the *Administering Oracle GoldenGate for Windows and UNIX* for more information about using macros.

**Default**

# (pound symbol)

**Syntax**

MACROCHAR character

**character**

The character to be used as the macro character. Valid user-defined macro characters are letters, numbers, and special characters such as the ampersand (&) or the underscore (_).

**Example**

In the following example, $ is defined as the macro character.

MACROCHAR $
MACRO $mymac
PARAMS ($p1)
BEGIN
col = $p1
END;
MAP for Extract

Valid For

Extract (Oracle databases only)

Description

Use the MAP parameter for Extract when Extract is operating in classic capture mode and you need to use the ALTID component of this parameter to map an object ID to an object name. ALTID specifies the correct object ID if Extract is capturing from Oracle transaction logs that were generated by a database other than the one to which Extract is connected. This configuration is required when Extract is not permitted to connect directly to the production (source) database to capture production transactions.

When Extract cannot connect directly to a source database, it connects to a live standby or other facsimile database, but it reads transaction logs that are sent from the source database. By querying the catalog of the alternate database, Extract can get the metadata that it needs to expand the transaction data into valid SQL statements, but it cannot use the object ID from this query. The local object ID for a table is different from the object ID of that table in the source database (and, thus, in the transaction log). You must manually map each table name to the source object ID by using a MAP statement with ALTID.

To use MAP with ALTID

- Create one MAP statement with ALTID for each table that you want to capture. Wildcarded table names are not allowed for a MAP parameter that contains ALTID.
- To specify other processing for the same table (or tables), such as data filtering or manipulation, you must also create a TABLE statement for each of those tables. Wildcarding can be used to specify multiple tables with one TABLE statement, if appropriate.
- Use a regular Replicat MAP statement in the Replicat parameter file, as usual. MAP for Extract does not substitute for MAP for Replicat, which is required to map source tables to target tables.
- DDL capture and replication is not supported when using ALTID.

Default

None

Syntax

MAP [container.]schema.table, ALTID object_ID [, object_ID]

[container.]schema.table
The fully qualified name of the source table.

object_ID
The object ID of the table as it exists in the production (source) database.

If a table is partitioned, you can list the object IDs of the partitions that you want to replicate, separating each with a comma.
Examples

Example 1
This example maps a non-partitioned table or just one partition of a partitioned table.

MAP QASOURCE.T2, ALTID 75740;

Example 2
This example maps partitions of a partitioned table.

MAP QASOURCE.T_P1, ALTID 75257,75258;
See "TABLE | MAP" on page 3-305.
MAPEXCLUDE

Valid For

Replicat

Description

Use the MAPEXCLUDE parameter with the MAP parameter to explicitly exclude source tables and sequences from a wildcard specification. MAPEXCLUDE must precede all MAP statements that contain the source objects that are being excluded. You can use multiple MAPEXCLUDE statements for specific MAP statements.

MAPEXCLUDE is evaluated before evaluating the associated MAP parameters. Thus, the order in which they appear does not make a difference.

When using wildcards, be careful not to place them such that all objects are excluded, leaving nothing to process. For example, the following example captures nothing:

MAP cat1.schema*.tab*, TARGET schema*.tab*
MAPEXCLUDE cat1.*.*

See also the EXCLUDEWILDCARDOBJECTSONLY parameter.

The default for resolving wildcards is WILDCARDRESOLVE DYNAMIC. Therefore, if a table that is excluded with MAPEXCLUDE is renamed to a name that satisfies a wildcard, the data will be captured. The DYNAMIC setting enables new table names that satisfy a wildcard to be resolved as soon as they are encountered and included in the Oracle GoldenGate configuration immediately. For more information, see WILDCARDRESOLVE.

Default

None

Syntax

MAPEXCLUDE [container. | catalog.]owner.(table | sequence)

container. | catalog.
If the source database requires three-part names, specifies the name or wildcard specification of the Oracle container or SQL/MX catalog that contains the object to exclude.

owner
Specifies the name or wildcard specification of the owner, such as the schema, of the object to exclude.

table | sequence
The name or wildcard specification of the source object to exclude. To specify object names and wildcards correctly, see Administering Oracle GoldenGate for Windows and UNIX.

Example

In this example, test.tab* specifies that all tables beginning with tab in schema test are to be excluded from all trail files. Table fin.acct is excluded from trail ee. Table fin.sales is excluded from trail ff.
MAPEXCLUDE  pdb1.test.tab*
MAP pdb1.*.*, TARGET *..*;
MAPEXCLUDE pdb2.fin.acct
MAP pdb2.*.*, TARGET *.::*;
MARKERTABLE

Valid For

GLOBALs

Description

Use the MARKERTABLE parameter to specify the name of the DDL marker table, if other than the default of GGS_MARKER. The marker table stores information about DDL operations.

The name of the marker table must also be specified with the marker_table_name parameter in the params.sql script. This script resides in the root Oracle GoldenGate installation directory.

This parameter is only valid for an Oracle database in which the capture configuration uses the Oracle GoldenGate DDL trigger to support DDL replication. For more information about the Oracle GoldenGate DDL objects, see Installing and Configuring Oracle GoldenGate for Oracle Database.

Default

GGS_MARKER

Syntax

MARKERTABLE [container.]table_name

[container.]table_name

The fully qualified three-part or two-part name of the marker table. To specify object names and wildcards correctly, see Administering Oracle GoldenGate for Windows and UNIX.
MAXDISCARDRECS

Valid For
Replicat

Description
Use the MAXDISCARDRECS parameter to limit the number of errors that are reported to the discard file per MAP statement.

Use this parameter for the following reasons:
- When you expect a large number of errors but do not want them reported.
- To manage the size of the discard file.

More than one instance of MAXDISCARDRECS can be used in a parameter file to specify different maximums for different sets of MAP statements. An instance of MAXDISCARDRECS applies to all subsequent MAP statements until the next instance of MAXDISCARDRECS is encountered.

Default
None

Syntax

```
MAXDISCARDRECS number
```

`number`
The maximum number of errors to report.

Example

```
MAXDISCARDRECS 1000
```
MAXGROUPS

Valid For

GLOBALS

Description

Use the MAXGROUPS parameter to specify the maximum number of process groups that can run in an instance of Oracle GoldenGate. The Manager process checks this parameter to determine its resource allocations. The GGSCI process checks this parameter to control the maximum number of groups that it allows to be created.

Each Replicat thread in a coordinated Replicat group is considered to be a group in the context of MAXGROUPS. Therefore, the value of the MAXTHREADS option of COORDINATED in the ADD_REPLICAT command (default is 25), plus the number of other Replicat and Extract groups in the Oracle GoldenGate instance, cannot exceed the MAXGROUPS value, or ADD_REPLICAT returns an error.

The actual number of processes that can run on a given system depends on the system resources that are available. If those resources are exceeded, Oracle GoldenGate returns errors regardless of the setting of MAXGROUPS.

Default

1000 groups

Syntax

MAXGROUPS number

number

The number of groups allowed in one instance of Oracle GoldenGate. Valid values are from 1000 to 5000.

Example

MAXGROUPS 1500
MAXSQLSTATEMENTS

Valid For
Replicat

Description
Use the MAXSQLSTATEMENTS parameter to control the number of prepared SQL statements that can be used by Replicat both in regular processing mode and in BATCHSQL mode. The value for MAXSQLSTATEMENTS determines the number of open cursors that Replicat maintains. Make certain that the database can support the specified number of cursors, plus the cursors that other applications and processes use. Before changing MAXSQLSTATEMENTS, contact Oracle Support.

When setting MAXSQLSTATEMENTS for a coordinated Replicat, take into account that the specified maximum number of cursors is applied to each thread in the configuration, not as an aggregate threshold for Replicat as a whole. For example, if MAXSQLSTATEMENTS 100 is specified, it is possible for each thread to have 99 open cursors without any warning or error from Replicat.

See “BATCHSQL” on page 3-26 for more information about BATCHSQL mode.

Default
250 cursors

Syntax
MAXSQLSTATEMENTS number

number
The maximum number of cursors that Replicat (or each thread in a coordinated Replicat) can use. Valid values are from 1 to 250.

Example
MAXSQLSTATEMENTS 200
**MAXTRANSOPS**

**Valid For**

Replicat (Not supported in integrated Replicat mode)

**Description**

Use the `MAXTRANSOPS` parameter to split large source transactions into smaller ones on the target system. This parameter can be used when the target database is not configured to accommodate large transactions. For example, if the Oracle rollback segments are not large enough on the target to reproduce a source transaction that performs one million deletes, you could specify `MAXTRANSOPS 10000`, which forces Replicat to issue a commit after each group of 10,000 deletes.

To use `MAXTRANSOPS` is to alter the transactional boundaries that are imposed by the source application, even though Replicat applies the operations in the correct order. This can cause errors if Extract fails during that transaction. Extract rewrites the transaction to the end of the trail, instead of overwriting the old one. Because the trail is sequential, Replicat starts processing the old transaction and must roll it back when it receives the recovery marker and the new transaction, and then start applying the new transaction. If `MAXTRANSOPS` caused Replicat to split the original transaction into multiple smaller transactions, Replicat may only be able to roll back the portion that was not committed to the target. When Replicat processes the committed operations again, they will result in duplicate-row errors or missing-row errors, depending on the SQL operation type.

---

**Note:** When troubleshooting Replicat abend errors, Oracle Support may request `GROUPTRANSOPS` to be set to 1 and `MAXTRANSOPS` to be set to 1. This is only a temporary configuration for troubleshooting purposes and should not be used permanently in production, or it will cause data integrity errors.

---

**Default**

10,000,000

**Syntax**

```sql
MAXTRANSOPS number
```

*number*

The number of operations to portion into a single transaction group.

**Example**

`MAXTRANSOPS 10000`
**MGRSERVNAME**

**Valid For**

GLOBALs

**Description**

Use the `MGRSERVNAME` parameter in a `GLOBALS` parameter file to specify the name of the Manager process when it is installed as a Windows service. This parameter is only required when installing multiple instances of Manager as a service on the same system, for example when installing multiple Oracle GoldenGate instances or when also installing the Oracle GoldenGate Veridata Agent, which uses a Manager process.

There must be a `GLOBALS` file containing `MGRSERVNAME` for each Manager service that is installed with the INSTALL utility. The files must be created before the services are installed, because the installation program refers to `MGRSERVNAME` when registering the service name on the system.

**Default**

None

**Syntax**

```
MGRSERVNAME name
```

*name*

A one-word name for the Manager service.

**Example**

```
MGRSERVNAME Goldengate
```
NAMECCSID

Valid for

GLOBALS, Extract, Replicat, DEFGEN for DB2 on IBM i

Description

Use the NAMECCSID parameter to specify the CCSID (coded character set identifier) of the database object names stored in the SQL catalog tables. The SQL catalog tables are created with the CCSID of the system, but the actual database object names could be represented in the catalog with characters from a different CCSID. The catalog does not indicate this difference when queried, and therefore Oracle GoldenGate could retrieve the name incorrectly unless NAMECCSID is present to supply the correct CCSID value.

To set the CCSID for a GGSCI session, use the SET NAMECCSID command.

To view the current CCSID, use the SHOW command. If the CCSID is not set through the GGSCI session or through the parameter NAMECCSID, the SHOW value will be DEFAULT.

Default

DEFAULT

Syntax

NAMECCSID {CCSID | DEFAULT}

CCSID

A valid DB2 for i coded character set identifier that is to be used for object names in catalog queries.

DEFAULT

Indicates that the system CCSID is to be used for object names in catalog queries.

Example

NAMECCSID 1141
NAMEMATCH parameters

Valid For

GLOBALs

Description

Use the NAMEMATCH parameters to control the behavior of fallback name mapping. Fallback name mapping is enabled by default when the source database is case-sensitive and the target database supports both case-sensitive and case-insensitive object names, such as Oracle, DB2 and SQL/MX.

By default (NAMEMATCHIGNORECASE) fallback name matching works as follows: When a source table name is case-sensitive, Oracle GoldenGate applies case-sensitive wildcard mapping on the target database to find an exact match. If the target database does not contain the exact target table name, including case, fallback name mapping performs a case-insensitive target table mapping to find a name match.

Default

NAMEMATCHIGNORECASE

Syntax

NAMEMATCHIGNORECASE | NAMEMATCHNOWARNING | NAMEMATCHEXACT

NAMEMATCHIGNORECASE
Performs a case-insensitive target table mapping to find a name match when the target database does not contain the exact target table name, including case.

NAMEMATCHNOWARNING
Outputs a warning message to the report file when fallback name matching is used.

NAMEMATCHEXACT
Disables fallback name mapping. If an exact, case-sensitive match is not found, Oracle GoldenGate returns an error and abends.
NOCATALOG

Valid For

DEFGEN

Description

Use NOCATALOG in the DEFGEN parameter file to remove the container name (Oracle) or the catalog name (SQL/MX) from table names before their definitions are written to the definitions file. This parameter is valid if the database supports container names or catalog names and the DEFSFILE parameter includes the FORMAT RELEASE option set to 12.1. Use this parameter if the definitions file is to be used for mapping to a database that only supports two-part names (owner.object).

DEFGEN abends with an error if duplicate schema.table names are encountered once the container or catalog names are removed. This prevents the possibility of processing errors caused by different sets of metadata having the same schema.table name when there is no catalog name to differentiate them.

Default

None

Syntax

NOCATALOG
NOHEADERS

Valid For

Extract

Description

Use the NOHEADERS parameter to indicate that an extract file contains no record headers. In this case, Replicat assumes that the input file contains only insert records for a single table and that each record is of the same length and type.

The FORMATASCII parameter with the NOHDRFIELDS option must be used in the Extract parameter file when using NOHEADERS. When NOHEADERS is used, only one source table can be specified across all MAP statements.

Default

None

Syntax

NOHEADERS
NODUPMSGSUPPRESSION

Valid For

GLOBALS

Description

Use NODUPMSGSUPPRESSION to prevent the automatic suppression of duplicate informational and warning messages in the report file, the error log, and the system log files. A message is issued to indicate how many times a message was repeated.

Default

Automatically suppress duplicate messages

Syntax

NODUPMSGSUPPRESSION
NUMFILES

Valid For

Extract and Replicat

Description

Use the NUMFILES parameter to control the initial number of memory structures that are allocated to contain information about tables specified in TABLE or MAP statements. NUMFILES must occur before any TABLE or MAP entries, and before the SOURCEDEFS or TARGETDEFS parameter, to have any effect.

When setting NUMFILES for a coordinated Replicat, take into account that the specified value is applied to each thread in the configuration, not as an aggregate threshold for Replicat as a whole. For example, if NUMFILES 500 is specified, it is possible for each thread to have 499 initial memory structures without any warning or error from Replicat.

To control the number of additional memory structures that are allocated dynamically once the NUMFILES value is reached, use the ALLOCFILES parameter. See "ALLOCFILES" on page 3-14 for more information. The default values should be sufficient for both NUMFILES and ALLOCFILES, because memory is allocated by the process as needed, system resources permitting.

Default

1000

Syntax

NUMFILES number

number

The initial number of memory structures to be allocated. Do not set NUMFILES to an arbitrarily high number, or memory will be consumed unnecessarily. The memory of Oracle GoldenGate supports up to two million tables.

Example

NUMFILES 4000
OBEY

Valid For

Extract and Replicat

Description

Use the OBEY parameter to retrieve parameter settings from a file other than the current parameter file.

To use OBEY, create and save a parameter file that contains the parameters that you want to retrieve. This is known as an OBEY file. You can create a library of OBEY files that contain different, frequently used parameter settings. Then, use the OBEY parameter in the active parameter file to invoke the parameters in the OBEY file.

Upon encountering an OBEY parameter in the active parameter file, Oracle GoldenGate processes the parameters from the OBEY file and then returns to the active parameter file to process any remaining parameters.

OBEY statements cannot be nested within other OBEY statements.

Instead of using OBEY, or in addition to it, you can use Oracle GoldenGate macros to retrieve frequently used parameters. For more information about using macros, see the Administering Oracle GoldenGate for Windows and UNIX.

Default

None

Syntax

OBEY file

file
The relative or fully qualified name of the file from which to retrieve parameters or commands.

Example

OBEY /home/ogg/myparms
OUTPUTFILEUMASK

Valid For

GLOBAL

Description

Use the OUTPUTFILEUMASK parameter to specify an octal umask for Oracle GoldenGate processes to use when creating trail files and discard files. OUTPUTFILEUMASK is not valid for Windows systems.

Default

Umask of 0 (all privileges)

Syntax

OUTPUTFILEUMASK umask

umask
The umask value. Must be between 0 and 0777; otherwise there will be an error: Missing or invalid option for OUTPUTFILEUMASK.

Example

OUTPUTFILEUMASK 066
OVERRIDEDUPS | NOOVERRIDEDUPS

Valid For

Replicat

Description

Use the OVERRIDEDUPS and NOOVERRIDEDUPS parameters to control whether or not Replicat overwrites an existing record in the target database with a replicated one if both records have the same key.

- **OVERRIDEDUPS** overwrites the existing record. It can be used for initial loads where you do not want to truncate target tables prior to the load, or for the resynchronization of a target table with a trusted source. Use the SQLDUPERR parameter with OVERRIDEDUPS to specify the numeric error code that is returned by the database for duplicate INSERT operations. See "SQLDUPERR" on page 3-288 for more information.

- **NOOVERRIDEDUPS**, the default, generates a duplicate-record error instead of overwriting the existing record. You can use an exceptions MAP statement with a S QLEXEC clause to initiate a response to the error. Otherwise, the transaction may abend. For more information about exceptions maps, see *Administering Oracle GoldenGate for Windows and UNIX*.

To bypass duplicate records without causing Replicat to abend when an exceptions map is not available, specify a REPERROR parameter statement similar to the following, where *error* is the database error number for primary key constraint errors.

REPER ROR (error, IGNORE)

For example, the statement for an Oracle database would be:

REPER ROR (1, IGNORE)

Replicat writes ignored duplicate records to the discard file.

Place OVERRIDEDUPS or NOOVERRIDEDUPS before the TABLE or MAP statements that you want it to affect. You can create different rules for different groups of TABLE or MAP statements. The parameters act as toggles: one remains in effect for subsequent TABLE or MAP statements until the other is encountered.

OVERRIDEDUPS is enabled automatically when HANDLECOLLISIONS is used. See "HANDLECOLLISIONS | NOHANDLECOLLISIONS" on page 3-162 for more information.

Caution: When OVERRIDEDUPS is in effect, records might not be processed in chronological order across multiple Replicat processes.

Default

NOOVERRIDEDUPS

Syntax

OVERRIDEDUPS | NOOVERRIDEDUPS
**Oracle GoldenGate Parameters**

**PASSTHRU | NOPASSTHRU**

**Valid For**

Extract

**Description**

Use the PASSTHRU and NOPASSTHRU parameters to control whether a data-pump Extract processes tables in pass-through mode or in normal mode. In pass-through mode (configured by PASSTHRU), the Extract process does not look up table definitions from the database or from a data-definitions file. Normally, Extract logs into the database to retrieve data definitions and, if the target is NonStop, read a data-definitions file. Extract refers to the definitions when it performs mapping and conversion.

By using pass-through mode, you can cascade captured data to a data pump on an intermediary system that does not host a database. To use pass-through mode, the source and target table names and structures must be identical. Filtering, column mapping, SQLEXEC functions, transformation, or other functions that require data manipulation or translation cannot be used. The WILDCARDRESOLVE parameter must be set to DYNAMIC (the default). If the Oracle GoldenGate installation uses a master-key wallet for data security, PASSTHRU causes the data pump to pass the data to its output trail in its encrypted form automatically.

The default of NOPASSTHRU causes the data pump to look up object definitions from a local database or a definitions file. When NOPASSTHRU is used and the Oracle GoldenGate installation uses a master-key wallet for data security, NOPASSTHRU causes the data pump to decrypt the data automatically, in expectation of further processing, and then re-encrypt the data before writing it to the output trail.

The PASSTHRU and NOPASSTHRU parameters are TABLE-specific. One parameter remains in effect for all subsequent TABLE statements, until the other parameter is encountered. This enables you to specify pass-through behavior for one set of tables while using normal processing, including data filtering and other manipulation, for other tables.

Because an intermediary system does not host a database, the tables that require filtering or other manipulation must be associated with a source-definitions file if filtering is to be performed, and with a target-definitions file if column mapping or conversion is to be performed. These files provide the metadata needed by Oracle GoldenGate to perform those actions in the absence of the database. For more information about data-definitions files, see *Administering Oracle GoldenGate for Windows and UNIX*. For more information about using an intermediary system, see *Administering Oracle GoldenGate for Windows and UNIX*.

In PASSTHRU mode, the data pump will not perform automatic ASCII-to-EBCDIC or EBCDIC-to-ASCII conversion.

**PASSTHRU in DDL Replication**

DDL is propagated by a data pump in PASSTHRU mode automatically. As a result, DDL that is performed on a source table of a certain name (for example `ALTER TABLE TableA` ...) is processed by the data pump using the same name (`ALTER TABLE TableA`). The name cannot be mapped by the data pump as `ALTER TABLE TableB`, regardless of any TABLE statements that specify otherwise.

**Default**

NOPASSTHRU
Syntax

PASSTHRU | NOPASSTHRU

Example

The following parameter file configures pass-through mode for all data from fin.acct, but allows normal processing for fin.sales.

EXTRACT fin
USERIDALIAS tiger1
RMTHOST sysb, MGRPORT 7809, ENCRYPT AES192 KEYNAME mykey
ENCRYPTTRAIL AES192
RMTTRAIL /ggs/dirdat/rt
PASSTHRU
TABLE fin.acct;
NOPASSTHRU
TABLE fin.sales, WHERE (ACCOUNT-CODE < 100);
PASSTHRUMESSAGES | NOPASSTHRUMESSAGES

Valid For

Extract

Description

Use the PASSTHRUMESSAGES and NOPASSTHRUMESSAGES parameters to control whether or not Extract writes messages for tables that are being processed in pass-through mode to the Extract report file. If enabled, messages similar to the following are written:

PASSTHRU mapping resolved for source table table name

Default

PASSTHRUMESSAGES

Syntax

PASSTHRUMESSAGES | NOPASSTHRUMESSAGES
**PORT**

**Valid For**
Manager

**Description**
Use the PORT parameter to specify a TCP/IP port number for the Manager process on which to interact with remote processes that request dynamic services, typically either an initial-load Replicat or the Collector process. Use the default port number when possible.

**Default**
Port 7809

**Syntax**
```
PRT number
```

*number*
An available port number.

**Example**
```
PORT 7809
```
PRESERVETARGETTIMEZONE

Valid For

Replicat

Description

Use the PRESERVETARGETTIMEZONE parameter to override the default Replicat session time zone. By default, Replicat sets its session to the time zone of the source database, as written to the trail by Extract. PRESERVETARGETTIMEZONE causes Replicat to set its session to the time zone of the target database.

Default

None

Syntax

PRESERVETARGETTIMEZONE
Valid For

Manager

Description

Use the PURGEDDLHISTORY and PURGEDDLHISTORYALT parameters to control the size of the DDL history tables that support DDL capture. These tables are created in an Oracle database to support trigger-based DDL capture.

These parameters cause Manager to purge rows that are not needed any more. You can specify the maximum and minimum amount of time to keep a row, based on the last modification date. Both maximum and minimum rules must be specified; otherwise Manager does not have a complete criteria for when to delete the row. For example, MINKEEPHOURS 3 used with MAXKEEPHOURS 5 specifies to keep rows that have not been modified in the past three hours, but to delete them when they have not been modified for at least five hours.

These parameters require a logon to be specified with the USERID or USERIDALIAS parameter.

---

**Caution:** Use caution when purging the history tables. They are critical to the integrity of the DDL synchronization processes. Premature purges are non-recoverable through Oracle GoldenGate. To prevent any possibility of permanent DDL data loss, make regular backups of the Oracle GoldenGate DDL schema.

---

Default

Purge every hour

Syntax

```
PURGEDDLHISTORY | PURGEDDLHISTORYALT
{, max_rule}
[, min_rule]
[, frequency]
```

**PURGEDDLHISTORY**

Purges the DDL history table. This table tracks DDL operations. To determine the name of the history table to purge, Oracle GoldenGate first looks for a name specified with the DDLTABLE parameter in theGLOBALS file. If that parameter does not exist, Oracle GoldenGate uses the default name of GGS_DDL_HIST.

**PURGEDDLHISTORYALT**

Purges the internal DDL history table. This table tracks partitioned object IDs that are associated with the object ID of a table. To determine the name of the internal history table to purge, Oracle GoldenGate first looks for a name specified with the DDLTABLE parameter in theGLOBALS file and appends ALT to it. If that parameter does not exist, Oracle GoldenGate uses the default name of GGS_DDL_HIST_ALT.

**max_rule**

Required. Can be one of the following to set the maximum amount of time to keep rows.
**MAXKEEPHOURS n**
Purges if the row has not been modified for \( n \) number of hours.

**MAXKEEPDAYS n**
Purges if the row has not been modified for \( n \) number of days.

**min_rule**
Can be one of the following to set the minimum amount of time to keep rows.

**MINKEEPHOURS n**
Keeps an unmodified row for at least the specified number of hours.

**MINKEEPDAYS n**
Keeps an unmodified row for at least the specified number of days.

**frequency**
Sets the frequency with which to purge DDL history. The default interval at which Manager evaluates potential maintenance tasks is 10 minutes, as specified with the CHECKMINUTES parameter. At that interval, Manager evaluates the PURGEDDLHISTORY or PURGEDDLHISTORYALT frequency and conducts the purge at the specified frequency.

**frequency** can be one of the following:

**FREQUENCYMINUTES n**
Sets the frequency, in minutes, with which to purge DDL history. The default purge frequency is 60 minutes.

**FREQUENCYHOURS n**
Sets the frequency, in hours, at which to purge DDL history.

See "CHECKMINUTES" on page 3-52 for more information about controlling the interval between Manager maintenance checks.

**Example**

The following example keeps all rows that have not been modified in the past three days and deletes them when they have not been modified for at least five days. The purge frequency is 30 minutes.

PURGEDDLHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 5, FREQUENCYMINUTES 30
**PURGEMARKERHISTORY**

**Valid For**
Manager

**Description**
Use the `PURGEMARKERHISTORY` parameter to control the size of the Oracle GoldenGate marker table. This parameter purges rows that are not needed any more. You can purge the marker table at any time. This parameter is only valid for an Oracle database in which the capture configuration uses the Oracle GoldenGate DDL trigger to support DDL replication. For more information about the Oracle GoldenGate DDL objects, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

To determine the name of the marker table, Oracle GoldenGate first looks for a name specified with the `MARKERTABLE` parameter in the `GLOBALS` file. If that parameter does not exist, Oracle GoldenGate uses the default name of `GGS_MARKER`.

You can specify maximum and minimum lengths of time to keep a row, based on the last modification date. Both maximum and minimum rules must be specified; otherwise Manager does not have complete criteria for when to delete the row. For example, `MINKEEPHOURS 3` used with `MAXKEEPHOURS 5` specifies to keep rows that have not been modified in the past three hours, but delete them when they have not been modified for at least five hours.

`PURGEMARKERHISTORY` requires a logon to be specified with the `USERID` or `USERIDALIAS` parameter and, depending on the type of database, the `SOURCEDB` parameter.

**Default**
Purge every hour

**Syntax**

```
PURGEMARKERHISTORY
{, max_rule}
[, min_rule]
[, frequency]
```

`max_rule`
Required. Can be one of the following to set the maximum amount of time to keep rows.

- `MAXKEEPHOURS n`
Purges if the row has not been modified for `n` number of hours.

- `MAXKEEPDAYS n`
Purges if the row has not been modified for `n` number of days.

`min_rule`
Can be one of the following to set the minimum amount of time to keep rows.

- `MINKEEPHOURS n`
Keeps an unmodified row for at least the specified number of hours.

- `MINKEEPDAYS n`
Keeps an unmodified row for at least the specified number of days.
**frequency**
Sets the frequency with which to purge marker history. The default interval at which Manager evaluates potential maintenance tasks is 10 minutes, as specified with the CHECKMINUTES parameter. At that interval, Manager evaluates the PURGEMARKERHISTORY frequency and conducts the purge at the specified frequency.

*frequency* can be one of the following:

- **FREQUENCYMINUTES n**
  Sets the frequency, in minutes, with which to purge marker history. The default purge frequency is 60 minutes.

- **FREQUENCYHOURS n**
  Sets the frequency, in hours, at which to purge marker history.

  See "CHECKMINUTES" on page 3-52 for more information about controlling the interval between Manager maintenance checks.

**Example**

The following example keeps all rows that have not been modified in the past three days and deletes them when they have not been modified for at least five days. The purge frequency is 30 minutes.

PURGEMARKERHISTORY MINKEEPDAYS 3, MAXKEEPDAYS 5, FREQUENCYMINUTES 30
PURGEOLDEXTRACTS for Extract and Replicat

Valid For

Extract and Replicat

Description

Use the PURGEOLDEXTRACTS parameter in an Extract or Replicat parameter file to delete old trail files whenever Oracle GoldenGate starts processing from a new one. Preventing the accumulation of trail files conserves disk space. Purges are conducted after the process is done with the file as indicated by checkpoints.

Purging by Extract is appropriate if the process is a data pump. After the data is sent to the target system, the files can be purged. Otherwise, purging would ordinarily be done by Replicat.

PURGEOLDEXTRACTS should only be used in an Extract or Replicat parameter file if there is only one instance of the process. If multiple groups are reading the same set of trail files, one process could purge a file before another is finished with it. Instead, use the Manager version of PURGEOLDEXTRACTS, which is the preferred use of the parameter in all Oracle GoldenGate configurations because it allows you to manage trail files in a centralized fashion.

Default

Purge the trail file when moving to the next file in the sequence.

Syntax

PURGEOLDEXTRACTS
PURGEOLDEXTRACTS for Manager

Valid For
Manager

Description
Use the PURGEOLDEXTRACTS parameter in a Manager parameter file to purge trail files when Oracle GoldenGate has finished processing them. Without using PURGEOLDEXTRACTS, no purging is performed, and trail files can consume significant disk space.

Using PURGEOLDEXTRACTS as a Manager parameter is preferred over using the Extract or Replicat version of PURGEOLDEXTRACTS. As a Manager parameter, PURGEOLDEXTRACTS allows you to manage trail files in a centralized fashion and take into account multiple processes.

How to Use PURGEOLDEXTRACTS for Manager
To control the purging, follow these rules:

- USECHECKPOINTS triggers a purge when all processes are finished with a file as indicated by their checkpoints. Basing the purges on checkpoints ensures that Manager does not delete any data until all processes are finished with it. This is essential in a production environment to ensure data integrity. USECHECKPOINTS considers the checkpoints of both Extract and Replicat before purging. Because USECHECKPOINTS is the default, it need not be specified in the PURGEOLDEXTRACTS statement. Manager obeys USECHECKPOINTS unless there is an explicit NOUSECHECKPOINTS entry.

- Use the MINKEEP rules to set a minimum amount of time to keep data:
  - Use MINKEEPHOURS or MINKEEPDAYS to keep data for \( n \) hours or days.
  - Use MINKEEPFILES to keep at least \( n \) trail files including the active file. The default number of files to keep is 1.

Use only one of the MINKEEP options. If more than one is used, Oracle GoldenGate selects one of them based on the following:

- If both MINKEEPHOURS and MINKEEPDAYS are specified, only the last one is accepted, and the other is ignored.
- If either MINKEEPHOURS or MINKEEPDAYS is used with MINKEEPFILES, then MINKEEPHOURS or MINKEEPDAYS is accepted, and MINKEEPFILES is ignored.

Manager evaluates potential maintenance tasks based on the value set for the CHECKMINUTES parameter. When that value is reached, Manager determines which files to purge based on the Extract and Replicat processes configured on the local system. If at least one process reads a trail file, Manager applies the specified rules; otherwise, the rules do not take effect. The following are possible PURGEOLDEXTRACT rule combinations and the actions that Manager takes for them:

- USECHECKPOINTS without MINKEEP rules: If checkpoints indicate that a file has been processed completely, it will be purged unless doing so would violate the default rule to keep at least one file.
- **USECHECKPOINTS** with **MINKEEP** rules: If checkpoints indicate that a file has been processed completely, it will be purged unless doing so would violate the **MINKEEP** rules.

- **NOUSECHECKPOINTS** without **MINKEEP** rules: The checkpoints are not considered, and the file will be purged unless doing so would violate the default rule to keep at least one file.

- **NOUSECHECKPOINTS** with **MINKEEP** rules: A file will be purged unless doing so would violate the **MINKEEP** rules.

**Additional Guidelines for PURGEOLDEXTRACTS for Manager**

- Do not use more than 500 **PURGEOLDEXTRACTS** parameter statements in the same Manager parameter file.

- When using this parameter, do not permit trail files to be deleted by any user or program other than Oracle GoldenGate. It will cause **PURGEOLDEXTRACTS** to function improperly.

- When trails are stored on NFS, there is a difference in system time between the NFS drive and the local system where Manager is running. The trail is created with the NFS time, but the timestamps of the records in the trail are compared with the local system time to determine whether to purge them or not. Take into account any time differences when you create your **MINKEEP** rules.

**Default**

**USECHECKPOINTS**

**Syntax**

```
PURGEOLDEXTRACTS trail
[, USECHECKPOINTS | NOUSECHECKPOINTS]
[, MINKEEP_rule]
[, frequency]
```

- `trail` The trail to purge. Use a relative or fully qualified name.

**USECHECKPOINTS**

Allows purging according to any **MINKEEP** rules after all Extract and Replicat processes are done with the data as indicated by checkpoints. When using **USECHECKPOINTS**, you can use the **USERID** or **USERIDALIAS** parameters in the Manager parameter file, so that Manager can query the Replicat checkpoint table to get checkpoint information though it is not required.

**NOUSECHECKPOINTS**

Allows purging without considering checkpoints, based either on the default rule to keep a minimum of one file (if no **MINKEEP** rule is used) or the number of files specified with a **MINKEEP** rule.

**MINKEEP_rule**

Can be one of the following to set rules for the minimum amount of time to keep an inactive file.

- **MINKEEPHOURS n**
  Keeps an inactive file for at least the specified number of hours.
MINKEEPDAYS $n$
Keeps an inactive file for at least the specified number of days.

MINKEEPFILES $n$
Keeps at least $n$ trail files, including the active file.

`frequency`
Sets the frequency with which to purge inactive trail files. The default time for Manager to evaluate potential maintenance tasks is 10 minutes, as specified with the CHECKMINUTES parameter. At that interval, Manager evaluates the PURGEOLDEXTRACTS frequency and conducts the purge after the specified `frequency`.

`frequency` can be one of the following:

FREQUENCYMINUTES $n$
Sets the frequency in minutes. The default purge frequency is 60 minutes.

FREQUENCYHOURS $n$
Sets the frequency in hours.

See "CHECKMINUTES" on page 3-52 for more information about controlling the Manager maintenance check interval.

Examples

**Example 1**

*Status*: Trail files AA000000, AA000001, and AA000002 exist. Replicat has been stopped for four hours and is not finished processing any of the files. The Manager parameters include:

```
PURGEOLDEXTRACTS /ggs/dirdat/AA*, USECHECKPOINTS, MINKEEPHOURS 2
```

*Result*: The amount of time that files must be retained was exceeded, but no files will be purged because checkpoints indicate that Replicat is not finished processing them.

**Example 2**

*Status*: Trail files AA000000, AA000001, and AA000002 exist. Replicat has been stopped for four hours and is not finished processing any of the files. The Manager parameters include:

```
PURGEOLDEXTRACTS /ggs/dirdat/AA*, NOUSECHECKPOINTS, MINKEEPHOURS 2
```

*Result*: All of the trail files will be purged because the minimum time to keep them was satisfied, and checkpoints are not considered before purging.

**Example 3**

*Status*: Replicat and Extract are finished processing data. There has been no access to the trail files for the last five hours. Trail files AA000000, AA000001, and AA000002 exist. The Manager parameters include:

```
PURGEOLDEXTRACTS /ggs/dirdat/AA*, USECHECKPOINTS, MINKEEPHOURS 4, & MINKEEPFILES 4
```

*Result*: This is an example of why only one of the MINKEEP options should be set. USECHECKPOINTS requirements were satisfied, so the MINKEEP rules are considered when determining whether to purge AA000002. Only two files will remain if AA000002 is purged, and that violates the MINKEEPFILES rule. Because both MINKEEPFILES and
MINKEEPHOURS are specified, however, MINKEEPFILES is ignored. The file will be purged because it has not been accessed for five hours, and that satisfies the MINKEEPHOURS requirement of four hours.
**PURGEOLDTASKS**

**Valid For**

Manager

**Description**

Use the **PURGEOLDTASKS** parameter to purge Extract and Replicat tasks after a specific amount of time or after they have stopped gracefully. You can indicate when to delete a task according to the following rules:

- The task was last started a specific number of days or hours ago. If the task never was started, its creation time is used as the basis for applying the rules.
- The task stopped gracefully or never was started. This rule takes precedence over the time the task was last started. Use this rule to prevent abnormally terminated tasks from being purged.

No more than 300 **PURGEOLDTASKS** parameter statements may be used in the same Manager parameter file.

**Default**

None

**Syntax**

```
PURGEOLDTASKS (EXTRACT | REPLICAT | ER) group
(AFTER number (DAYS | HOURS) | USESTOPSTATUS)
```

**EXTRACT | REPLICAT | ER**

The process for which you want to purge tasks. Use the **ER** option to specify both Extract and Replicat process types.

**group**

The group name or a wildcard to specify multiple groups.

**AFTER number (DAYS | HOURS)**

Purges if the task has not been updated for a specified number of days or hours.

**USESTOPSTATUS**

Purges if the task was stopped gracefully or never was started.

**Example**

The following example deletes all Extract tasks that have not been updated for at least three days, and it deletes the *test_rep* Replicat task if it stopped gracefully and has not been updated for at least two hours.

```
PURGEOLDTASKS EXTRACT *, AFTER 3 DAYS
PURGEOLDTASKS REP test_rep, AFTER 2 HOURS, USESTOPSTATUS
```
RECOVERYOPTIONS

Valid For

Extract

Description

Use the RECOVERYOPTIONS parameter to control how Extract handles the re-writing of data to the trail after it fails while in the process of writing transaction data.

Append Mode

By default, Extract operates in append mode. In this mode, Extract writes a recovery marker to the trail after a failure, and then it appends the recaptured recovery data to the file, instead of overwriting the original data. Append mode retains a history of all prior data.

During recovery in append mode, Extract determines the identity of the last complete transaction that it wrote to the trail and then completes its recovery when the commit record for that transaction is encountered in the data source. A data pump or Replicat starts reading again from that recovery point. Extract starts capturing new data at the start of the next committed transaction after the recovery point, and this new data is appended to the trail file.

Overwrite Mode

Overwrite mode is another version of Extract recovery that was used in versions of Oracle GoldenGate prior to version 10.0. In these versions, Extract overwrites the original transaction data with recaptured data, instead of appending the new data. The next transaction that Extract captures is the first one after the last read checkpoint in the data source.

In overwrite mode, there is a probability that the overwrite might not deposit precisely the same record images, in precisely the same sequence, as the originals that are being overwritten. This can happen when Extract must fetch large objects or when Extract configuration parameters have been changed. Between the time when overwrite activity begins and the time when Extract reaches the end of the trail file, any such changes will create a misalignment at the leading edge of the overwritten portion of the file. When this happens, the end of the last record that was rewritten does not fall on a boundary that is shared by the beginning of a record that was written by the previous instance of Extract. A Replicat or data pump that is trying to read from one trail record to the next starts somewhere in the middle of a corrupted record and then abends with an error.

Recommendations

Do not change RECOVERYOPTIONS from the default of APPENDMODE unless instructed to do so by an Oracle Support analyst. If Extract is permitted to overwrite existing data in the trail, it might be harder for Oracle GoldenGate to recover after a failure, and it might cause the loss of data.

In some cases, Extract automatically reverts to overwrite mode to support backward compatibility if the version of Oracle GoldenGate on the target is older than Oracle GoldenGate version 10. Older versions do not support append mode.
Parameter Dependencies

There is a dependency between the `RECOVERYOPTIONS` parameter and the `FORMAT` option of `EXTFILE`, `EXTTRAIL`, `RMTFILE`, and `RMTTRAIL`. When `RECOVERYOPTIONS` is set to `APPENDMODE`, the `FORMAT` option must be set to `RELEASE 10.0` or greater. When `RECOVERYOPTIONS` is set to `OVERWRITEMODE`, the `FORMAT` option must be set to `RELEASE 9.5` or less.

Default

`APPENDMODE`

Syntax

`RECOVERYOPTIONS {APPENDMODE | OVERWRITEMODE}`

**APPENDMODE**

Appends new data to the original data in a trail file. This is the default.

**OVERWRITEMODE**

Overwrites original data with new data, starting at the most recent checkpoint position.

Example

`RECOVERYOPTIONS OVERWRITEMODE`
REPERROR

Valid For

Replicat

Description

Use the REPERROR parameter to control how Replicat responds to errors. The default response of Replicat to any error is to abend.

You can use one REPERROR statement to handle most errors in a default manner, while using one or more other REPERROR statements to handle specific errors differently. For example, you can ignore duplicate-record errors but abend processing in all other cases.

You can use REPERROR globally (at the root of the parameter file) to affect all MAP statements that follow it, or you can use it within a MAP statement to affect the tables specified in that statement. Using REPERROR within a MAP statement gives you the ability to handle errors in a particular way for each thread of a coordinated Replicat.

Using Record-level Error Handling

All REPERROR options except TRANSDISCARD and TRANSEXCEPTION apply an error-handling action in response to an individual SQL operation on an individual record. Other, error-free records in the same transaction are processed as configured in the MAP statements and other parameters in the parameter file, as applicable.

Using Transaction-level Error Handling

The TRANSDISCARD, TRANSEXCEPTION, and ABEND options apply an error-handling action to an entire transaction. The triggering error can occur on an individual record in the transaction or on the commit operation. (Commit errors do not have a particular record associated with them.) These options can be used to:

- prevent an entire source transaction from being replicated to the target when any error is associated with it.
- respond to a commit error when deferred constraint checking is enabled on the target.

TRANSDISCARD and TRANSEXCEPTION are mutually exclusive.

Effect of Other Parameters on Transaction-level Options

TRANSDISCARD and TRANSEXCEPTION honor the boundaries of the source transaction; however, the presence of BATCHSQL, GROUPTRANSOPS, or MAXTRANSOPS in the parameter file may affect the error-handling logic or outcome, because they alter transaction boundaries.

Effect of BATCHSQL and GROUPTRANSOPS

BATCHSQL or GROUPTRANSOPS (the default) both group SQL operations from different transactions into larger transactions to improve performance, while maintaining transactional order. When these parameters are in effect and any error occurs, Replicat first tries to resolve it by entering an alternate processing mode (see the documentation for those parameters). If the error persists, TRANSDISCARD or TRANSEXCEPTION comes into effect, and Replicat reverts to source-processing mode as follows:
Oracle GoldenGate Parameters

1. It rolls back the grouped or arrayed transaction.

2. It replays the offending transaction one SQL operation at a time, using the same transaction boundaries as the source transaction.

3. It performs the discard logic (TRANSDISCARD) or exceptions-mapping (TRANSEXCEPTION). (See those option descriptions for more detail.)

4. It resumes BATCHSQL or GROUPTRANSOPS mode after the TRANSDISCARD error handling is completed.

Effect of MAXTRANSOPS
The integrity of TRANSDISCARD and TRANSEXCEPTION transaction-level error handling can be adversely affected by the setting of the MAXTRANSOPS parameter. MAXTRANSOPS causes Replicat to split very large replicated source transactions into smaller transactions when it applies them on the target.

The TRANSDISCARD and TRANSEXCEPTION logic cause Replicat to roll back to the first record after the last successful commit. This may or may not be the actual beginning of the offending transaction. It depends on whether that transaction was split up and parts of it are in the previously committed transactions. If that is the case, Replicat cannot apply the TRANSDISCARD or TRANSEXCEPTION action to the whole transaction as it was issued on the source, but only to the part that was rolled back from the target.

If you use MAXTRANSOPS, make certain that it is set to a value that is larger than the largest transaction that you expect to be handled by TRANSDISCARD and TRANSEXCEPTION. This will ensure that transactions are not be split apart into smaller ones on the target.

Effect of Transaction-level Options on Statistics
The output of informational commands in GGSCI, such as STATS REPLICAT, will show the total number of records in the transaction that was processed by TRANSDISCARD or TRANSEXCEPTION logic. This number may reflect the following:

- Replicat writes all records of the transaction to the discard file, including any records that were excluded from Oracle GoldenGate processing by means of a FILTER or WHERE clause in a MAP statement.
- If a source table in the transaction has multiple targets, the discarded transaction will contain multiple copies of each record, one for each target.
- Replicat ignores any exceptions mapping statements (as specified with EXCEPTIONONLY or MAPEXCEPTION in a MAP statement) when discarding the transaction.

Replicat abends on errors that are caused by the discard processing (TRANSDISCARD) or exceptions mapping (TRANSEXCEPTION).

Getting More Information about Error Handling
See Administering Oracle GoldenGate for Windows and UNIX for more information about configuring error handling.

See "TABLE | MAP" on page 3-305 for more information about the MAP parameter.

Default

TRANSABORT for deadlocks; ABEND for all others
Syntax

REPERROR {  
  (  
    {DEFAULT | DEFAULT2 | SQL_error | user_defined_error},  
    {ABEND |  
    DISCARD |  
    EXCEPTION |  
    IGNORE |  
    RETRYOP [MAXRETRIES n] |  
    TRANSABORT [, MAXRETRIES] [, DELAYSECS n | DELAYCSECS n] |  
    TRANSDISCARD |  
    TRANSEXCEPTION  
  )  
)  
RESET }

Error Specification Options

DEFAULT
Sets a global response to all errors except those for which explicit REPERROR statements are specified.

DEFAULT2
Provides a backup default action when the response for DEFAULT is set to EXCEPTION. Use DEFAULT2 when an exceptions MAP statement is not specified for a MAP statement for which errors are anticipated.

SQL_error
A SQL error number. This can be a record-level error or a commit-level error if using TRANSDISCARD and TRANSEXCEPTION.

user_defined_error
A user-defined error that is specified with the RAISEERROR option of a FILTER clause within a MAP statement.

Error Response Options

ABEND
Rolls back the transaction and terminates processing abnormally. ABEND is the default.

DISCARD
Logs the offending operation to the discard file but continue processing the transaction and subsequent transactions.

EXCEPTION
Handles the operation that causes an error as an exception, but processes error-free operations in the transaction normally. Use this option in conjunction with an exceptions MAP statement or to work with the MAPEXCEPTION option of MAP. For example, you can map columns from failed update statements into a "missing updates" table. In the parameter file, specify the exceptions MAP statement after the MAP statement for which the error is anticipated.

EXCEPTION applies exception handling only to an individual SQL operation on an individual record. To apply exception handling to the entire transaction, use the TRANSEXCEPTION option.
**Note:** When the Conflict Detection and Resolution (CDR) feature is active, CDR automatically treats all operations that cause errors as exceptions if an exceptions MAP statement exists for the affected table. In this case, REPERRO error with EXCEPTION is not necessary, but you should use REPERRO with other options to handle conflicts that CDR cannot resolve, or for conflicts that you do not want CDR to handle.

**IGNORE**

Ignores the error.

**RETRYOP [MAXRETRIES n]**

Retries the offending operation. Use the MAXRETRIES option to control the number of retries. For example, if a table is out of extents, RETRYOP with MAXRETRIES gives you time to add extents so the transaction does not fail. Replicat aborts after the specified number of MAXRETRIES.

**TRANSABORT [, MAXRETRIES n] [, DELAYSECS n | DELAYCSECS n]**

Aborts the transaction and repositions to the beginning of the transaction. This sequence continues either until the record(s) are processed successfully or MAXRETRIES expires. If MAXRETRIES is not set, the TRANSABORT action will loop continuously.

Use one of the DELAY options to delay the retry. DELAYSECS n sets the delay in seconds and the default is 60 seconds. DELAYCSECS n sets the delay in centiseconds.

The TRANSABORT option is useful for handling timeouts and deadlocks on databases that support those conditions.

**TRANS DISCARD**

Discards the entire source transaction if any operation within that transaction, including the commit operation, causes a Replicat error that is listed in the REPERRO error specification. Replicat aborts the transaction and, if the error occurred on a record, writes that record to the discard file. Replicat then replays the transaction and writes all of the records to the discard file, including the commit record. Replicat aborts on errors that are caused by the discard processing.

If the discarded record has already been data-mapped to a target record, Replicat writes it to the discard file in the target format; otherwise, it will be written in source format. The replayed transaction itself is always written in source format.

TRANS DISCARD supports record-level errors as well as commit errors.

Additional information is at the beginning of this topic.

**TRANSEXCEPTION**

If an error specified with REPERRO occurs on any record in a transaction, performs exceptions mapping for every record in the transaction according to its corresponding exceptions-mapping specification, as defined by a MAP EXCEPTION or EXCEPTIONSONLY clause in an exceptions MAP statement. If any record does not have a corresponding exceptions mapping specification, or if there is an error writing to the exceptions table, Replicat aborts with an error message.

When an error is encountered and TRANSEXCEPTION is being used, Replicat aborts the transaction and, if the error occurred on a record, writes that record to the discard file. Replicat replays the transaction and examines the source records to find the exceptions-mapping specifications, and then executes them.
TRANSEXCEPTION supports record-level errors as well as commit errors. To handle errors at the record level (for individual SQL operations), without affecting error-free operations in the same transaction, use the EXCEPTION option in a MAP statement.

RESET
Use a REPERROR RESET statement to remove error-handling rules specified in previous REPERROR parameters and apply default error handling to all MAP statements that follow.

Examples of Using REPERROR Globally

These examples show REPERROR as used at the root of the parameter file to set global error-handling rules. You can override any or all of these rules for any given table or tables by using REPERROR in a MAP statement. See "Examples of Using REPERROR Globally and in a MAP Statement" on page 3-231.

Example 1
The following example demonstrates how to stop processing for most errors, but ignore duplicate-record errors.

REPERROR (DEFAULT, ABEND)
REPERROR (-1, IGNORE)

Example 2
The following example invokes an exceptions MAP statement created to handle errors on the account table. Errors on the product table cause Replicat to end abnormally because an exceptions MAP statement was not defined.

REPERROR (DEFAULT, EXCEPTION)
REPERROR (DEFAULT2, ABEND)
MAP sales.product, TARGET sales.product;
MAP sales.account, TARGET sales.account;
INSERTALLRECORDS
MAP sales.account, TARGET sales.account_exception,
EXCEPTIONONLY,
COLMAP (account_no = account_no,
optype = @GETENV ('lasterr', 'optype'),
dberr = @GETENV ('lasterr', 'dberrnum'),
dberrmsg = @GETENV ('lasterr', 'dberrmsg'));

Example 3
The following applies error rules for the first MAP statement and then restores the default of ABEND to the second one.

REPERROR (-1, IGNORE)
MAP sales.product, TARGET sales.product;
REPERROR RESET
MAP sales.account, TARGET sales.account;

Example 4
The following discards the offending record and then replays the entire transaction if any operation on a record within it generates an error 1403. Other error types cause Replicat to abend.

REPERROR DEFAULT ABEND
REPERROR 1403 TRANSDISCARD
Example 5
The following discards the offending record and then replays the entire transaction to search for an exceptions-mapping specification that writes to the exceptions table that is named tgtexception. Other errors cause Replicat to discard the offending record (if applicable) and then abend.

REPERROR DEFAULT ABEND
REPERROR 1403 TRANSEXCEPTION
MAP src, TARGET tgt, &
MAPEXCEPTION (TARGET tgtexception, INSERTALLRECORDS, COLMAP (...) );

Examples of Using REPERROR Globally and in a MAP Statement
The following examples show different ways that REPERROR can be used in a MAP statement in conjunction with a global REPERROR statement.

Example 1
REPPLICAT group_name
REPERROR (error1, response1)
MAP src1, TARGET tgt1, REPERROR (error1, response2);
MAP src2, TARGET tgt2, REPERROR (error2, response3);

In the preceding example, when error1 occurs for the first MAP statement, the action should be response2, not response1, because an override was specified. However, if an error1 occurs for the second MAP statement, the response should be response1, the global response. The response for error2 would be response3, which is MAP-specific.

Example 2
REPPLICAT group_name
REPERROR (error1, response1)
MAP src1, TARGET tgt1, REPERROR (error2, response2),
REPERROR (error1, response3);

In the preceding example, when replicating from src1 to src2, all errors and actions (1-3) should apply, because all REPERROR statements address different errors (there are no MAP-specific overrides).

Example 3
REPPLICAT group_name
REPERROR (error1, response1)
MAP src1, TARGET tgt1, REPERROR (error1, response2);
MAP src2, TARGET tgt2, REPERROR (error2, response3);
REPERROR (error1, response4)
MAP src2, TARGET tgt2, REPERROR (error3, response3);

In the preceding example, if error1 occurs for the first MAP statement, the action should be response2. For the second one it would be response1 (the global response), and for the third one it would be response4 (because of the second REPERROR statement). A global REPERROR statement applies to all MAP statements that follow it in the parameter file until another REPERROR statement starts new rules.

Example 4
REPERROR DEFAULT ABEND
REPERROR 1403 TRANSDISCARD.
MAP src, TARGET tgt, REPERROR(600 TRANSDISCARD);
In the preceding example, if error 600 is encountered while applying source table src to target table tgt, the whole transaction is written to discard file. Encountering error 1403 also results in the same action based on the global REPERROR specification. On the other errors, the process simply discards only the offending record and then abends.
REPFETCHEDCOLOPTIONS

Valid For

Replicat

Description

Use the REPFETCHEDCOLOPTIONS parameter to determine how Replicat responds to operations for which a fetch from the source database was required. The Extract process fetches column data when the transaction record does not contain enough information to construct a SQL statement or when a FETCHCOLS clause is used. See "{(FETCHCOLS | FETCHCOLSEXCEPT) (column_list)}" on page 3-325 for more information.

Default

None

Syntax

REPFETCHEDCOLOPTIONS
[
   . INCONSISTENTROW ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . LATESTROWVERSION ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . MISSINGROW ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . NOFETCH ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . REDUNDANTROW ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . SNAPSHOTROW ALLOW|IGNORE|REPORT|DISCARD|ABEND
   . SETIFMISSING string]

INCONSISTENTROW
Determines the action to perform when column data was successfully fetched by row ID, but the key did not match. Either the row ID was recycled or a primary key update occurred after this operation (and prior to the fetch). Valid values are

ALLOW
Process the operation unless the record length is zero (0).

IGNORE
Ignore the condition and continue processing.

REPORT
Write the record to the discard file and process the operation.

DISCARD
Discard the data and do not process the row.

ABEND
Discard the data and quit processing.

LATESTROWVERSION action
Provides a response when column data was fetched from the current row in the table. Valid values are:

ALLOW
Process the operation unless the record length is zero (0).
IGNORE
Ignore the condition and continue processing.

REPORT
Write the record to the discard file and process the operation.

DISCARD
Discard the data and do not process the row.

ABEND
Discard the data and quit processing.

NOFETCH action
Prevents fetching. One use for this option is when the database is a standby and Oracle GoldenGate does not have a database connection. In this case, an attempt to fetch from the database would result an error. Other scenarios may warrant the use of this parameter as well.

When Oracle GoldenGate cannot fetch data it normally would fetch, it probably will cause data integrity issues on the target.

The following are valid actions that can be taken when a NOFETCH is encountered:

ABEND
Write the operation to the discard file and abend the Replicat process. This is the default.

ALLOW
Process the operation unless the record length is zero (0).

IGNORE
Ignore the operation. If fetch statistics are being reported in the process report (based on STATOPTIONS settings) they will be updated with this result.

REPORT
Write the record to the discard file and process the operation.

DISCARD
Write the record to the discard file, but do not process the operation. If fetch statistics are being reported in the process report (based on STATOPTIONS settings) they will be updated with this result.

MISSINGROW action
Provides a response when only part of a row (the changed values) is available to Replicat for processing. The column data that is missing from the trail typically could not be fetched because the row was deleted between the time the change record was created and when the fetch was triggered, or because the row image required was older than the undo retention specification.

Valid values are:

ALLOW
Process the operation unless the record length is zero (0).

IGNORE
Ignore the condition and continue processing.

REPORT
Write the record to the discard file and process the operation.
DISCARD
Discard the data and do not process the partial row.

ABEND
Discard the data and quit processing.

REDUNDANTROW
Indicates that column data was not fetched because column data was previously fetched for this record.

SETIFMISSING [string]
Provides a value when a fetch was unsuccessful (and the value is missing from the trail record) but the target column has a not-null constraint. It takes an optional ASCII string as a value for CHAR and BINARY data types or defaults to the following.

CHAR, VARCHAR: Single space
BINARY, VARBINARY: A NULL byte
TIMESTAMP: Current date/time
FLOAT, INTEGER: Zero

Besides SETIFMISSING, you can use the COLMAP clause of the MAP statement to map a value for the target column. See "COLMAP (column_mapping)" on page 3-309 for more information.

SNAPSHOTROW
Indicates that column data was fetched from a snapshot. Generally, this option would only be used for reporting or discarding operations. Valid values are:

ALLOW
Process the operation unless the record length is zero (0).

IGNORE
Ignore the condition and continue processing.

REPORT
Write the record to the discard file and process the operation.

DISCARD
Discard the data and do not process the row.

ABEND
Discard the data and quit processing.
REPLACEBADCHAR

Valid For

Extract and Replicat

Description

Use the REPLACEBADCHAR parameter to control the response of the process when a valid code point does not exist for either the source or target character set when mapping character-type columns. By default, the check for invalid code points is only performed when the source and target databases have different character sets, and the default response is to abend. You can use the FORCECHECK option to force the process to check for invalid code points when the source and target databases have the same character set. REPLACEBADCHAR applies globally.

Default

ABORT

Syntax

REPLACEBADCHAR {ABORT | SKIP | ESCAPE | SUBSTITUTE string | NULL | SPACE} [FORCECHECK] [NOWARNING]

ABORT
The process abends on an invalid code point. This is the default.

SKIP
The process skips the record that has the invalid code point. Use this option with caution, because skipping a record can cause data discrepancies on the target.

ESCAPE
The process replaces the data value with an escaped version of the data value. Depending on the character set of the source database, the value is output as one of the following:

- If the source data is not UTF-16 (NCHAR/NVARCHAR), the output is hexadecimal (\xXX).
- If the source data is UTF-16, the output is Unicode (\uXXXX).

SUBSTITUTE string
The process replaces the data with a specified string, either Unicode notation or up to four characters. By default the default substitution character of the target character set is used for replacement.

NULL
The process replaces an invalid character with the value of NULL if the target column is nullable or, otherwise, assigns a white space (U+0020).

SPACE
The process replaces an invalid character with a white space (U+0020).
FORCECHECK
The process checks for invalid code points when the source and target databases have identical character sets. This overrides the default, where the validation is skipped when the source and target character sets are identical.

NOWARNING
The process suppresses warning messages related to conversion and validation errors.

Examples

Example 1
The following example replaces invalid code points with the value of NULL.

REPLACEBADCHAR NULL

Example 2
Because ESCAPE is specified, Oracle GoldenGate will replace the Euro symbol in a source NCHAR column with the escaped version of \u20AC, because the target is ISO-8859-1, which does not support the Euro code point.

REPLACEBADCHAR ESCAPE

Example 3
The following substitutes a control character for invalid characters.

REPLACEBADCHAR SUBSTITUTE \u001A
REPLACEBADNUM

Valid For
Replicat

Description
Use the REPLACEBADNUM parameter to specify a substitution value for invalid numeric data encountered when mapping number columns. REPLACEBADNUM applies globally.

Default
Replace invalid numbers with NULL.

Syntax
REPLACEBADNUM {number | NULL | UNPRINTABLE}

number
Replace with the specified number.

NULL
Replace with NULL if the target column accepts NULL values; otherwise replace with zero.

UNPRINTABLE
Reject any column with unprintable data. The process stops and reports the bad value.

Examples

Example 1
REPLACEBADNUM 1

Example 2
REPLACEBADNUM NULL
REPLICAT

Valid For
Replicat

Description
Use the REPLICAT parameter to specify a Replicat group for online change synchronization. This parameter links the current run with previous runs, so that data changes are continually processed to maintain synchronization between source and target tables. Replicat will run continuously and maintain checkpoints in the data source and trail to ensure data integrity and fault tolerance throughout planned or unplanned process termination, system outages, or network failure.

Either REPLICAT or SPECIALRUN is required in the Replicat parameter file and must be the first entry. See "SPECIALRUN" on page 3-287 for more information.

Default
None

Syntax
REPLICAT group_name

group_name
The group name as defined with the ADD REPLICAT command. To view the names of existing Replicat groups, use the INFO REPLICAT * command.

Example
REPLICAT finance
REPORT

Valid For
Extract and Replicat

Description
Use the REPORT parameter to specify the interval at which Extract or Replicat generates interim runtime statistics in a process report. The statistics are added to the existing report. By default, runtime statistics are displayed at the end of a run unless the process is intentionally killed.

The statistics for REPORT are carried over from the previous report. For example, if the process performed 10 million inserts one day and 20 million the next, and a report is generated at 3:00 each day, then the first report would show the first 10 million inserts, and the second report would show those plus the current day's 20 million inserts, totalling 30 million. To reset the statistics when a new report is generated, use the STATOPTIONS parameter with the RESETREPORTSTATS option. See "STATOPTIONS" on page 3-301 for more information.

For more information about the process reports, see Administering Oracle GoldenGate for Windows and UNIX.

Default
Generate runtime statistics at the end of each run.

Syntax
REPORT
{AT hh:mm | ON day | AT hh:mm ON day}

AT hh:mm
Generates the report at a specific time of the day. Using AT without ON generates a report at the specified time every day.

ON day
Generates the report on a specific day of the week. Valid values are:
SUNDAY
MONDAY
TUESDAY
WEDNESDAY
THURSDAY
FRIDAY
SATURDAY

The values are not case-sensitive.

Examples

Example 1
REPORT AT 17:00
Example 2
REPORT ON SUNDAY AT 1:00
REPORTCOUNT

Valid For

Extract and Replicat

Description

Use the REPORTCOUNT parameter to report a count of transaction records that Extract or Replicat processed since startup. Each transaction record represents a logical database operation that was performed within a transaction that was captured by Oracle GoldenGate. The record count is printed to the report file and to the screen.

Note: This count might differ from the number of records that are contained in the Oracle GoldenGate trail. If an operation affects data that is larger than 4K, it must be stored in more than one trail record. Hence, a report count might show 1,000 records (the database operations) but a trail count might show many more records than that. To obtain a count of the records in a trail, use the Logdump utility.

You can schedule record counts at regular intervals or after a specific number of records. Record counts are carried over from one report to the other.

REPORTCOUNT can be used only once in a parameter file. If there are multiple instances of REPORTCOUNT, Oracle GoldenGate uses the last one.

Default

None

Syntax

REPORTCOUNT [EVERY] count
{RECORDS | SECONDS | MINUTES | HOURS} [, RATE]

count
The interval after which to output a count.

RECORDS | SECONDS | MINUTES | HOURS
The unit of measure for count, in terms of records, seconds, minutes, or hours.

RATE
Reports the number of operations per second and the change in rate, as a measurement of performance. See Example 2. The Rate statistic is the total number of records divided by the total time elapsed since the process started. The Delta statistic is the number of records since the last report divided by the time since the last report.

Note: The calculations are done using microsecond time granularity. The time intervals are shown without fractional seconds, and the rate values are shown as whole numbers.
Examples

Example 1
This example generates a record count every 5,000 records.

REPORTCOUNT EVERY 5000 RECORDS

Example 2
This example generates a record count every ten minutes and also reports processing statistics.

REPORTCOUNT EVERY 10 MINUTES, RATE

The processing statistics are similar to this:

12000 records processed as of 2011-01-01 12:27:40 (rate 203, delta 308)
REPORTROLLOVER

Valid For
Extract and Replicat

Description
Use the REPORTROLLOVER parameter to force report files to age on a regular schedule, instead of when a process starts. For long or continuous runs, setting an aging schedule controls the size of the active report file and provides a more predictable set of archives that can be included in your archiving routine.

Note: Report statistics are carried over from one report to the other. To reset the statistics in the new report, use the STATOPTIONS parameter with the RESETREPORTSTATS option.

You can specify a time of day, a day of the week, or both. Specifying just a time of day (AT option) without a day of the week (ON option) generates a report at the specified time every day.

Rollovers caused by this parameter do not generate runtime statistics in the process report:
- To control when runtime statistics are generated to report files, use the REPORT parameter.
- To generate new runtime statistics on demand, use the SEND EXTRACT or SEND REPLICAT command with the REPORT option.

Default
Roll reports at startup

Syntax
REPORTROLLOVER
{AT hh:mi | ON day | AT hh:mi ON day}

AT hh:mi
The time of day to age the file.
Valid values:
- hh is based on a 24-hour clock and accepts values of 1 through 23.
- mi accepts values from 00 through 59.

ON day
The day of the week to age the file. Valid values are:
- SUNDAY
- MONDAY
- TUESDAY
- WEDNESDAY
- THURSDAY
REPORTROLLOVER

FRIDAY
SATURDAY

The values are not case-sensitive.

Examples

Example 1
REPORTROLLOVER AT 05:30

Example 2
REPORTROLLOVER ON friday

Example 3
REPORTROLLOVER AT 05:30 ON friday
**RESTARTCOLLISIONS | NORESTARTCOLLISIONS**

**Valid For**

Replicat

**Description**

Use the **RESTARTCOLLISIONS** and **NORESTARTCOLLISIONS** parameters to control whether or not Replicat applies **HANDLECOLLISIONS** logic after Oracle GoldenGate has stopped because of a conflict. By default, **NORESTARTCOLLISIONS** applies. However, there might be circumstances when you would want Oracle GoldenGate to apply **HANDLECOLLISIONS** logic for the first transaction after startup. For example, if the server is forcibly shut down, the database might have committed the last Replicat transaction, but Oracle GoldenGate might not have received the acknowledgement. Consequently, Replicat will retry the transaction upon startup. **HANDLECOLLISIONS** automatically handles the resultant errors that occur.

**RESTARTCOLLISIONS** enables **HANDLECOLLISIONS** functionality until the first Replicat checkpoint (transaction) is complete. You need not specify the **HANDLECOLLISIONS** parameter in the parameter file. After the first checkpoint, **HANDLECOLLISIONS** is automatically turned off.

See "**HANDLECOLLISIONS | NOHANDLECOLLISIONS**" on page 3-162 for more information about handling collisions.

**Default**

NORESTARTCOLLISIONS

**Syntax**

```
RESTARTCOLLISIONS | NORESTARTCOLLISIONS
```
RMTFILE

Valid For
Extract

Description
Use the RMTFILE parameter to define the name of an extract file on a remote system to which extracted data will be written. Use this parameter for initial-load configurations. For online change synchronization, use the RMTTRAIL parameter.

The size of an extract file cannot exceed 2GB.

RMTFILE must be preceded by a RMTHOST statement, and it must precede any TABLE statements.

You can encrypt the data in this file by using the ENCRYPTTRAIL parameter. See "ENCRYPTTRAIL | NOENCRYPTTRAIL" on page 3-119 for more information.

Default
None

Syntax
RMTFILE file_name
[. APPEND]
[. PURGE]
[. MAXFILES number]
[. MEGABYTES megabytes]
[. FORMAT RELEASE major.minor]
[. TRAILBYTEORDER {BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN}]

file_name
The relative or fully qualified name of the file.

APPEND
Adds the current data to existing data in the file. If you use APPEND, do not use PURGE.

PURGE
Deletes an existing file before creating a new one. If you use PURGE, do not use APPEND.

MAXFILES number
Forces a sequence of files to be created, rather than a single file. Use this option when you expect the size of a file to exceed the limit permitted by the operating system.

MAXFILES permits as many files to be created as needed. Aged files are appended with a six-digit sequence number, for example datafile000002.

When using MAXFILES, also use MEGABYTES to set the maximum size of each file in the sequence.

Checkpoints are not maintained in these files.

MEGABYTES megabytes
Defines the maximum size of the file (or of each file created when MAXFILES is used). The size of a remote file cannot exceed 2GB.
**FORMAT RELEASE major.minor**

Specifies the metadata format of the data that is sent by Extract to the file. The metadata tells the reader process whether the data records are of a version that it supports. The metadata format depends on the version of the Oracle GoldenGate process. Older Oracle GoldenGate versions contain different metadata than newer ones.

- FORMAT is a required keyword.
- RELEASE specifies an Oracle GoldenGate release version. major is the major version number, and minor is the minor version number. The x.x must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate x.x version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.)

The release version is programmatically mapped back to an appropriate internal compatibility level. The default is the current version of the process that writes to this trail. Note that RELEASE versions earlier than 12.1 do not support three-part object names.

There is a dependency between FORMAT and the RECOVERYOPTIONS parameter. When RECOVERYOPTIONS is set to APPENDMODE, FORMAT must be set to RELEASE 10.0 or greater. When RECOVERYOPTIONS is set to OVERWRITEMODE, FORMAT must be set to RELEASE 9.5 or less.

**TRAILBYTEORDER (BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN)**

Sets the byte format of the metadata in the file records. This parameter does not affect the column data. Valid only for files that have a FORMAT RELEASE version of at least 12.1. Valid values are BIGENDIAN (big endian), LITTLEENDIAN (little endian), and NATIVEENDIAN (default of the local system). The default is BIGENDIAN. See the GLOBALS version of TRAILBYTEORDER for additional usage instructions.

**Examples**

**Example 1**

RMTFILE /ggs/dirdat/salesny, MEGABYTES 2, PURGE

**Example 2**

RMTFILE /ggs/dirdat/salesny, MEGABYTES 2, FORMAT RELEASE 10.4
RMTHOST

Valid For

Extract

Description

Use the RMTHOST parameter to:

- Identify a remote system to which the local Extract process connects
- Specify the TCP/IP port number on that system where the Manager process is running
- Control various attributes of the TCP/IP connections

This parameter controls compression, data encryption, buffer attributes, TCP/IP streaming, connection timeout threshold, and the wait period for a connection request. It also can be used to set Collector parameters.

To identify multiple remote systems in a parameter file, use one RMTHOST statement for each one, followed by the associated trails and table maps, for example:

```
EXTRACT sales
USERIDALIAS tiger1
RMTHOST ny, MGRPORT 7888, ENCRYPT AES 192 KEYNAME mykey
RMTTRAIL /ggs/dirdat/aa
TABLE ora.orders;
RMTHOST la, MGRPORT 7888, ENCRYPT AES 192 KEYNAME mykey2
RMTTRAIL /ggs/dirdat/bb
TABLE ora.orders;
```

Do not use RMTHOST for an Extract created in PASSIVE mode. See "ADD EXTRACT" on page 1-14 for more information about a passive Extract.

Oracle GoldenGate supports IPv4 and IPv6 protocols. See "USEIPV4" on page 3-403 for more information about the selection of internet protocol.

The RMTHOST and RMTHOSTOPTIONS parameters can be specified together; the RMTHOST parameter is not required for RMTHOSTOPTIONS if the dynamic IP assignment is properly configured. When RMTHOSTOPTIONS is used, the MGRPORT option is ignored.

Default

None

Syntax

```
RMTHOST
{ host name | IP address}
[, COMPRESS]
[, COMPRESSSTHRESHOLD]
[, ENCRYPT algorithm [KEYNAME key_name]]
[, MGRPORT port | PORT port]
[, CPU number]
[, PRI number]
[, HOMETERM device_name]
[, PROCESSNAME process_name]
[, PARAMS collector_parameters]
[, STREAMING | NOSTREAMING]
```
The DNS host name or IP address of the target system. You can use either one to define the host. If using an IP address, use either an IPv6 or IPv4-mapped address, depending on the stack of the destination system.

**COMPRESS**
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Compresses outgoing blocks of records to reduce bandwidth requirements. Oracle GoldenGate decompresses the data before writing it to the trail. **COMPRESS** typically results in compression ratios of at least 4:1 and sometimes better. However, compressing data can consume CPU resources.

**COMPRESSTHRESHOLD**
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Sets the minimum block size for which compression is to occur. Valid values are from 0 and through 28000. The default is 1,000 bytes.

**ENCRYPT algorithm [KEYNAME key_name]**
This option is valid for online or batch Extract processes and all Oracle GoldenGate initial-load methods. Encrypts the data stream sent over TCP/IP to the target system. This option supports the following encryption options:

- **Master key and wallet method**: Generate a session key based on the active master key and algorithm specified. Not valid for DB2 on z/OS, DB2 for i, and SQL/MX.
- **ENCKEYS method**: Generate an AES encryption key, store it under a given name in an ENCKEYS file, and configure Oracle GoldenGate to use that key to encrypt the data.

**algorithm**
Specifies the encryption algorithm to use:

- **AES128** uses the AES-128 cipher, which has a key size of 128 bits. AES128 is the default if no algorithm is specified.
- **AES192** uses the AES-192 cipher, which has a key size of 192 bits.
- **AES256** uses the AES-256 cipher, which has a key size of 256 bits.
- **BLOWFISH** uses Blowfish encryption with a 64-bit block size and a variable-length key size from 32 bits to 128 bits. Use BLOWFISH for backward compatibility with earlier Oracle GoldenGate versions and for Oracle GoldenGate installations for DB2 on z/OS, DB2 for i, and SQL/MX on NonStop. On those platforms, BLOWFISH is the only supported encryption method. Use AES where supported, because it is more secure than BLOWFISH for those platforms.

**KEYNAME key_name**
Specifies that the ENCKEYS method of encryption will be used. Not valid for the master key and wallet method. For **key_name**, specify the logical name of the user-defined encryption key. Oracle GoldenGate uses the key name to look up the actual key in the ENCKEYS lookup file. To use the ENCKEYS method, you must:

- Generate the encryption key.
- Store it in an ENCKEYS lookup file.
- Copy ENCKEYS to every system where encryption or decryption (or both) are performed.

To use AES encryption for any database other than Oracle on a 32-bit platform, the path of the lib sub-directory of the Oracle GoldenGate installation directory must be specified as an environment variable before starting any processes. This is not required on 64-bit platforms. Set the path as follows:

- UNIX: Specify the path as an entry to the LD_LIBRARY_PATH or SHLIB_PATH variable. For example:
  ```
  setenv LD_LIBRARY_PATH ./lib:$LD_LIBRARY_PATH
  ```

- Windows: Add the path to the PATH variable.

You can use the SETENV parameter to set the library as a session variable for the process.

For more information about using encryption, see Administering Oracle GoldenGate for Windows and UNIX.

**MGRPORT | PORT**

Either MGRPORT or PORT is required. MGRPORT is the port on the remote system where Manager runs. PORT is the port number of a static Collector process. Either a Manager port (if using a dynamic Collector) or a static Collector port must be specified. See “Collector Parameters” on page 4-1 for more information about a static Collector.

**CPU number**

Valid for SQL/MX. Specifies the number of the CPU to be used for the process. Valid values are numbers 1 - 15 and -1 is default, which is assigned 1 higher than the last Manager started.

**PRI number**

Valid for SQL/MX. Specifies the Extract process priority. Valid values are numbers 1 - 199 and -1 is the default, and is the same as the manager process priority.

**HOMETERM device_name**

Valid for SQL/MX. Specifies the name of the device to be used and must be a terminal or process. It can be entered in either Guardian $ or OSS /G/yyyyyyyy form. The default is $zhome or the current session HOMETERM when $zhome is not defined.

**PROCESSNAME process_name**

Valid for SQL/MX. Specifies the name of the process as alphanumeric string up to five characters and can be entered in either Guardian $ or OSS /G/yyyyyyyy form. The default is a system generated process name.

**PARAMS collector_parameters**

Specifies Collector parameters on a NonStop target system

---

**Note:** Do not specify a Collector port (-p argument) if Manager will be starting Collector dynamically.

---

For more information about Collector parameters on the NonStop platform, see Reference for Oracle GoldenGate for Mainframe for HP NonStop Guardian.
STREAMING | NOSTREAMING
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Controls TCP/IP streaming.

STREAMING
Enables the asynchronous internet streaming protocol and is the default. In STREAMING mode, the receiver (Collector) does not send an acknowledgement to the sender (primary Extract or data pump) for any data packet unless the packet contains a flag requesting a response, typically when the sender must checkpoint or determine a write position. Because this method omits acknowledgements, the sender or receiver process terminates if there is a network disruption; therefore, when using STREAMING, use the AUTORESTART parameter in the Manager parameter file to restart Extract and Collector if they terminate.

NOSTREAMING
Enables the synchronous internet protocol. In NOSTREAMING mode, the sender sends a packet and then waits for the receiver to acknowledge it, before sending the next packet. This method is more reliable, because it enables the sender or receiver process to recover if there is a network disruption.

Extract falls back to the synchronous protocol automatically if the host system of the receiver process is not configured to use streaming.

Keep the STREAMING default unless you are requested to disable it, because streaming reduces transmission latency, especially in networks where latency is a problem already. Streaming is not supported for initial-load tasks where Extract communicates directly with Replicat.

TCPBUFSIZE bytes
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Controls the size of the TCP socket buffer, in bytes, that Extract will try to maintain.

By increasing the size of the buffer, you can send larger packets to the target system. The actual size of the buffer depends on the TCP stack implementation and the network. The default is 30,000 bytes, but modern network configurations usually support higher values. Valid values are from 1000 to 200000000 (two hundred million) bytes. Work with your network administrator to determine an optimal value. See also Administering Oracle GoldenGate for Windows and UNIX for more information about tuning the buffer size and other suggestions for improving the transfer of data across the network.

Testing has shown that using TCPBUFSIZE for initial loads produces three times faster throughput than loads performed without it. Do not use this parameter if the target system is NonStop.

TCPFLUSHBYTES bytes
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Controls the size of the buffer, in bytes, that collects data that is ready to be sent across the network.

When either this value or the value of the FLUSHSECS parameter is reached, the data is flushed to the target. The default is 30,000 bytes. Valid values are from 1000 to 200000000 (two hundred million) bytes, but should be at least the value of TCPBUFSIZE.

Do not use this parameter for an initial load Extract. It is valid only for an online Extract group. Do not use this parameter if the target system is NonStop.
**TIMEOUT seconds**
This option is valid for online or batch Extract processes and any Oracle GoldenGate initial-load method that uses trails. Specifies how long Collector waits to get a connection from Extract, and how long Collector waits for a heartbeat signal from Extract before terminating a connection. Valid values are 1 second to 1800 seconds (30 minutes). The default value is 300 seconds (5 minutes). Setting the timeout to a very low value is not recommended in a production setting. You might need to increase the **TIMEOUT** value if you see a warning in the error log that there was a TCP/IP error 10054 (existing connection forcibly closed by remote host). This error typically occurs when the Collector terminates itself after the **TIMEOUT** value is exceeded. This parameter does not affect a static Collector.

**Examples**

**Example 1**
RMTHOST 20.20.20.17, MGRPORT 7809, ENCRYPT AES192, KEYNAME newyork

**Example 2**
RMTHOST 20.20.20.17, MGRPORT 7809, ENCRYPT AES192

**Example 3**
RMTHOST newyork, MGRPORT 7809, COMPRESS, COMPRESSSTHRESHOLD 750, NOSTREAMING

**Example 4**
RMTHOST newyork, MGRPORT 7809, TCPBUFSIZE 100000, TCPFLUSHBYTES 300000

**Example 5**
RMTHOST newyork, MGRPORT 18819, CPU 1, PRI 140, HOMETERM $ZTN0.##PTJ52A1, PROCESSNAME $xyz1
RMTHOSTOPTIONS

Valid For

Passive Extract

Description

Use the RMTHOSTOPTIONS parameter to control attributes of a TCP/IP connection made between an Extract group running in PASSIVE mode on a less trusted source to a target system in a more secure network zone. This parameter controls compression, data encryption, buffer attributes, streaming, and the wait period for a connection request. It also can be used to set Collector parameters.

This parameter differs from the RMHOST parameter because it does not provide the host information needed to establish a remote connection. When Extract is running in PASSIVE mode, all connections between source and target are established by an alias Extract group on the target.

All parameter options must be specified in one RMTHOSTOPTIONS statement. If multiple RMTHOSTOPTIONS statements are used, the last one in the parameter file is used, and the others are ignored. RMTHOSTOPTIONS overrides any RMHOST statements in the file.

See RMHOST for additional information about supported IP protocols.

The RMHOST and RMTHOSTOPTIONS parameters can be specified together; the RMHOST parameter is not required for RMTHOSTOPTIONS if the dynamic IP assignment is properly configured. When RMTHOSTOPTIONS is used, the MGRPORT option is ignored.

For more information about using Oracle GoldenGate in a zoned network, see Administering Oracle GoldenGate for Windows and UNIX.

Default

None

Syntax

RMTHOSTOPTIONS
[, COMPRESS]
[, COMPRESSTHRESHOLD]
[, ENCRYPT algorithm [KEYNAME key_name]]
[, PARAMS collector_parameters]
[, STREAMING | NOSTREAMING]
[, TCPBUFSIZE bytes]
[, TCPFLUSHBYTES bytes]
[, TIMEOUT seconds]

COMPRESS

Compresses outgoing blocks of records to reduce bandwidth requirements. Oracle GoldenGate decompresses the data before writing it to the trail. COMPRESS typically results in compression ratios of at least 4:1 and sometimes better. However, compressing data can consume CPU resources.

COMPRESSTHRESHOLD

Sets the minimum block size for which compression is to occur. Valid values are from 0 and through 28000. The default is 1,000 bytes.
ENCRYPT algorithm [KEYNAME key_name]
Encrypts the data stream sent over TCP/IP to the target system. This option supports the following encryption options:

- **Master key and wallet method**: Generate a one-time AES key to encrypt the data across the TCP/IP network. Then, the one-time key is encrypted by the master-key and stored in the trail file header.

- **ENCKEYS method**: Generate an AES encryption key, store it under a given name in an ENCKEYS file, and configure Oracle GoldenGate to use that key to directly encrypt the data across the TCP/IP network.

  **algorithm**
  Specifies the encryption algorithm to use:
  - AES128 uses the AES-128 cipher, which has a key size of 128 bits. AES128 is the default if no algorithm is specified.
  - AES192 uses the AES-192 cipher, which has a key size of 192 bits.
  - AES256 uses the AES-256 cipher, which has a key size of 256 bits.
  - BLOWFISH uses Blowfish encryption with a 64-bit block size and a variable-length key size from 32 bits to 128 bits. Use BLOWFISH for backward compatibility with earlier Oracle GoldenGate versions and for Oracle GoldenGate installations for DB2 on z/OS, DB2 for i, and SQL/MX on NonStop. On those platforms, BLOWFISH is the only supported encryption method. Use AES where supported, because it is more secure than BLOWFISH for those platforms.

  **KEYNAME key_name**
  Specifies that the ENCKEYS method of encryption will be used. Not valid for the master key and wallet method. For key_name, specify the logical name of the user-defined encryption key. Oracle GoldenGate uses the key name to look up the actual key in the ENCKEYS lookup file. To use the ENCKEYS method, you must:
  - Generate the encryption key.
  - Store it in an ENCKEYS lookup file.
  - Copy ENCKEYS to every system where encryption or decryption (or both) are performed.

To use AES encryption for any database other than Oracle on a 32-bit platform, the path of the lib sub-directory of the Oracle GoldenGate installation directory must be specified as an environment variable before starting any processes. This is not required on 64-bit platforms. Set the path as follows:

- **UNIX**: Specify the path as an entry to the LD_LIBRARY_PATH or SHLIB_PATH variable. For example:
  ```bash
  setenv LD_LIBRARY_PATH ./lib:$LD_LIBRARY_PATH
  ```

- **Windows**: Add the path to the PATH variable.

You can use the SETENV parameter to set the library as a session variable for the process.

For more information about using encryption, see the Administering Oracle GoldenGate for Windows and UNIX.

**PARAMS collector_parameters**
Specifies Collector parameters on a NonStop target system.
For more information about Collector parameters on the NonStop platform, see Reference for Oracle GoldenGate for Mainframe for HP NonStop Guardian.

**STREAMING | NOSTREAMING**

Controls TCP/IP streaming.

**STREAMING**

Enables the asynchronous internet streaming protocol and is the default. In **STREAMING** mode, the receiver (Collector) does not send an acknowledgement to the sender (primary Extract or data pump) for any data packet unless the packet contains a flag requesting a response, typically when the sender must checkpoint or determine a write position. Because this method omits acknowledgements, the sender or receiver process terminates if there is a network disruption; therefore, when using **STREAMING**, use the **AUTORESTART** parameter in the Manager parameter file to restart Extract and Collector if they terminate.

**NOSTREAMING**

Enables the synchronous internet protocol. In **NOSTREAMING** mode, the sender sends a packet and then waits for the receiver to acknowledge it, before sending the next packet. This method is more reliable, because it enables the sender or receiver process to recover if there is a network disruption.

Extract falls back to the synchronous protocol automatically if the host system of the receiver process is not configured to use streaming.

Keep the **STREAMING** default unless you are requested to disable it, because streaming reduces transmission latency, especially in networks where latency is a problem already. Streaming is not supported for initial-load tasks where Extract communicates directly with Replicat.

**TCPFLUSHBYTES bytes**

Controls the size of the buffer, in bytes, that collects data that is ready to be sent across the network. When either this value or the value of the **FLUSHSECS** parameter is reached, the data is flushed to the target.

The default is 30,000 bytes. Valid values are from 1000 to 20000000 (two hundred million) bytes, but should be at least the value of **TCPBUFSIZE**.

Do not use this parameter for an initial load Extract. It is valid only for an online Extract group. Do not use this parameter if the target system is NonStop.

**TIMEOUT seconds**

Specifies how long an Extract running in **PASSIVE** mode waits to get a connection from Collector, and how long Extract waits for a heartbeat signal from Collector before terminating a connection. Valid values are 1 second to 1800 seconds (30 minutes). The default value is 300 seconds (5 minutes). Setting the timeout to a very low value is not recommended in a production setting. You might need to increase the **TIMEOUT** value if you see a warning in the error log that there was a TCP/IP error 10054 (existing connection forcibly closed by remote host). This error typically occurs when the Extract terminates itself after the **TIMEOUT** value is exceeded.

**Example**

```
RMTHOSTOPTIONS ENCRYPT AES192, KEYNAME newyork, COMPRESS, COMPRESSTHRESHOLD 750,
```
TCPBUFFSIZE 100000, TCPFLUSHBYTES 300000, NOSTREAMING
RMTTASK

Valid For

Extract

Description

Use the RMTTASK parameter for an initial-load Extract to initiate a Replicat processing task during an Oracle GoldenGate direct load or a direct bulk load to SQL*Loader. RMTTASK directs Extract to communicate directly with Replicat over TCP/IP and bypasses the use of a Collector process or trail storage. RMTTASK also directs Extract to request that Manager start Replicat automatically, and then stop Replicat when the run is finished. Tasks do not use checkpoints.

Dependent parameters are as follows:

- A RMTHOST statement must follow each RMTTASK statement in the initial-load Extract parameter file.
- EXTRACT must be used in the initial-load Extract parameter file.
- REPLICAT must be used in the initial-load Replicat parameter file.
- SOURCEISTABLE must be used in the ADD EXTRACT command.
- SPECIALRUN must be used in the ADD REPLICAT command.

RMTTASK does not support encryption of any kind. To use encryption, you can use the initial-load method that writes data to a file, which is read by Replicat to load the data.

RMTTASK does not support tables that have columns that contain LOBs, LONGs, user-defined types (UDT), or any other large data type that is greater than 4k in size.

When using RMTTASK, do not start Replicat with the START REPLICAT command. Replicat is started automatically during the task.

See the Administering Oracle GoldenGate for Windows and UNIX for more information about performing initial data loads.

Default

None

Syntax

RMTTASK REPLICAT, GROUP group_name
[FMT RELEASE major.minor]

GROUP group_name
The group name of the Initial Load Replicat on the target system.

FORMAT RELEASE major.minor
Specifies the metadata format of the data that is sent by Extract to Replicat. The metadata tells Replicat whether the data records are of a version that it supports. The metadata format depends on the version of the Oracle GoldenGate process. Older Oracle GoldenGate versions contain different metadata than newer ones.

- FORMAT is a required keyword.
- RELEASE specifies an Oracle GoldenGate release version. major is the major version number, and minor is the minor version number. The X.x must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate X.x version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.)

The release version is programmatically mapped back to an appropriate internal compatibility level. The default is the current version of the process that writes to this trail. Note that RELEASE versions earlier than 12.1 do not support three-part object names.

There is a dependency between FORMAT and the RECOVERYOPTIONS parameter. When RECOVERYOPTIONS is set to APPENDMODE, FORMAT must be set to RELEASE 10.0 or greater. When RECOVERYOPTIONS is set to OVERWRITEMODE, FORMAT must be set to RELEASE 9.5 or less.

See Administering Oracle GoldenGate for Windows and UNIX for more information about initial loads.

Example

RMTTASK REPLICA, GROUP initrep, FORMAT RELEASE 10.0
RMTTRAIL

Valid For

Extract

Description

Use the RMTTRAIL parameter to specify a remote trail that was created with the ADD RMTTRAIL command in GGSCI. A trail specified with RMTTRAIL must precede its associated TABLE statements. Multiple RMTTRAIL statements can be used to specify different remote trails. RMTTRAIL must be preceded by a RMTHOST parameter.

You can encrypt the data in this trail by using the ENCRYPTTRAIL parameter. See "ENCRYPTTRAIL | NOENCRYPTTRAIL" on page 3-119 for more information.

Default

None

Syntax

RMTTRAIL trail_name
[ , FORMAT RELEASE major.minor]
[ , TRAILBYTEORDER {BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN}]

name

The relative or fully qualified path name of the trail. Use two characters for the name. As trail files are aged, a six-character sequence number will be added to this name, for example /ggs/dirdat/rt000001.

FORMAT RELEASE major.minor

Specifies the metadata format of the data that is sent by Extract to the trail. The metadata tells the reader process whether the data records are of a version that it supports. Older Oracle GoldenGate versions contain different metadata than newer ones.

- FORMAT is a required keyword.
- RELEASE specifies an Oracle GoldenGate release version. major is the major version number, and minor is the minor version number. The X.x must reflect a current or earlier, generally available (GA) release of Oracle GoldenGate. Valid values are 9.0 through the current Oracle GoldenGate X.x version number, for example 11.2 or 12.1. (If you use an Oracle GoldenGate version that is earlier than 9.0, specify either 9.0 or 9.5.)

The release version is programmatically mapped back to an appropriate internal compatibility level. The default is the current version of the process that writes to this trail. Note that RELEASE versions earlier than 12.1 do not support three-part object names.

There is a dependency between FORMAT and the RECOVERYOPTIONS parameter. When RECOVERYOPTIONS is set to APPENDMODE, FORMAT must be set to RELEASE 10.0 or greater. When RECOVERYOPTIONS is set to OVERWRITEMODE, FORMAT must be set to RELEASE 9.5 or less.

See Administering Oracle GoldenGate for Windows and UNIX for additional information about Oracle GoldenGate trail file versioning and recovery modes.
TRAILBYTEORDER (BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN)
Sets the byte format of the metadata in the trail records. This parameter does not affect
the column data. Valid only for trails that have a FORMAT RELEASE version of at least
12.1. Valid values are BIGENDIAN (big endian), LITTLEENDIAN (little endian), and
NATIVEENDIAN (default of the local system). The default is BIGENDIAN. See the GLOBALS
version of TRAILBYTEORDER for additional usage instructions.

Examples

Example 1
RMTTRAIL dirdat/ny

Example 2
RMTTRAIL /ggs/dirdat/ny, FORMAT RELEASE 10.4

Example 3
Two trail formats within the same sets of tables being captured:

FORMAT RELEASE 11.2
TABLE tab1
TABLE tab2
FORMAT RELEASE 12.1
TABLE tab1
TABLE tab2
**ROLLOVER**

**Valid For**

Extract

**Description**

Use the ROLLOVER parameter to specify the interval at which trail files are aged and new ones are created. ROLLOVER is global and applies to all trails defined with RMTTRAIL or RMTFILE statements in a parameter file.

Use ROLLOVER to create trail files that represent distinct periods of time (for example, each day). It facilitates continuous processing while providing a means for organizing the output. It also provides a means for organizing batch runs by deactivating one file and starting another for the next run.

Files roll over between transactions, not in the middle of one, ensuring data integrity. Checkpoints are recorded when files roll over to ensure that previous files are no longer required for processing.

Rollover occurs only if the rollover conditions are satisfied during the run. For example, if ROLLOVER ON TUESDAY is specified, and data extraction starts on Tuesday, the rollover does not occur until the next Tuesday (unless more precise ROLLOVER rules are specified). You can specify up to 30 rollover rules.

Either the AT or ON option is required. Both options can be used together, and in any order. Using AT without ON creates a new trail file at the specified time every day.

A trail sequence number can be incremented from 000001 through 999999, and then the sequence numbering starts over at 000000.

**Default**

Roll over when the default file size is reached or the size specified with the MEGABYTES option of the ADD RMTTRAIL or ADD EXTTRAIL command is reached.

**Syntax**

```
ROLLOVER {AT hh:mi | ON day | AT hh:mi ON day} [REPORT]
```

**AT hh:mi**

The time of day to age the file.

Valid values:

- hh is based on a 24-hour clock, with valid values of 1 through 23.
- mi accepts values from 00 through 59.

**ON day**

The day of the week to age the file.

Valid values:

- SUNDAY
- MONDAY
- TUESDAY
- WEDNESDAY
- THURSDAY
- FRIDAY
SATURDAY

The values are not case-sensitive.

REPORT
Generates a report for the number of records extracted from each table since the last report was generated. The report represents the number of records output to the corresponding trail unless other reports are generated by means of the REPORT parameter.

Examples

Example 1
The following ages trails every day at 3:00 p.m.
ROLLOVER AT 15:00

Example 2
The following ages trails every Sunday at 8:00 a.m.
ROLLOVER AT 08:00 ON SUNDAY
**SCHEMAEXCLUDE**

**Valid For**

Extract, Replicat, DEFGEN

**Description**

Use the `SCHEMAEXCLUDE` parameter to exclude source objects that are owned by the specified source owner (such as a schema) from the Oracle GoldenGate configuration when wildcards are being used to specify the owners in `TABLE` or `MAP` statements. This parameter is valid for two- and three-part names.

Wildcards can be used for the optional `catalog` or `container` specification, as well as the `schema` specification. Make certain not to use wildcards such that all objects are excluded. Follow the rules for using wildcards in *Administering Oracle GoldenGate for Windows and UNIX*.

The positioning of `SCHEMAEXCLUDE` in relation to parameters that specify files or trails determines its effect. Parameters that specify trails or files are: `EXTFILE`, `RMTFILE`, `EXTTRAIL`, `RMTTRAIL`. The parameter works as follows:

- When a `SCHEMAEXCLUDE` specification is placed before any `TABLE` or `SEQUENCE` parameters, and also before the parameters that specify trails or files, it applies globally to all trails or files, and to all `TABLE` and `SEQUENCE` parameters.
- When a `SCHEMAEXCLUDE` specification is placed after a parameter that specifies a trail or file, it is effective only for that trail or file and only for the `TABLE` or `SEQUENCE` parameters that are associated with it. Multiple trail or file specifications can be made in a parameter file, each followed by a set of `TABLE`, `SEQUENCE`, and `TABLEEXCLUDE` specifications.

`SCHEMAEXCLUDE` is evaluated before evaluating the associated `TABLE` or `SEQUENCE` parameters. Thus, the order in which they appear does not make a difference.

See also the `EXCLUDEWILDCARDOBJECTSONLY` parameter.

**Default**

None

**Syntax**

```plaintext
SCHEMAEXCLUDE [container. | catalog.]*schema
```

- **container. | catalog.**
  If the database requires three-part names, specifies the source Oracle container or SQL/MX catalog that contains the source owner that is to be excluded. Use if a qualifier is required to identify the correct owner to exclude.

- **schema**
  Specifies the name of the source owner that is to be excluded. For databases that require three-part names, you can use `schema` without `catalog` if the `SCHEMAEXCLUDE` specification precedes a set of `TABLE` or `MAP` parameters for which the default container or catalog is specified with the `SOURCECATALOG` parameter, or if the SQL/MX catalog is defined by the `SOURCEDB` or `TARGETDB` parameter.
Examples

Example 1
This example excludes the source test* schemas. Note that it omits the catalog specification from the owner name because the catalog is specified with the SOURCEDB parameter in a SQL/MX configuration.

```
EXTRACT capt
SOURCEDB catalog1, USERID schema1
RMTHOST sysb, MGRPORT 7809
RMTTRAIL /ggs/dirdat/aa
SCHEMAEXCLUDE test*
TABLE *.*;
```

Example 2
This Oracle example requires both catalog (container) and schema specifications and demonstrates how wildcards can be used as part of the specification.

```
EXTRACT capt
USERIDALIAS alias1
RMTHOST sysb, MGRPORT 7809
RMTTRAIL /ggs/dirdat/aa
SCHEMAEXCLUDE pdbtest.test*
TABLE pdb*.test*.*;
```

Example 3
This example shows how to use SCHEMAEXCLUDE when the database requires only a two-part name.

```
TABLE abc*.*/;
SCHEMAEXCLUDE abc*test*;
```
**SEQUENCE**

**Valid For**

Extract

**Description**

Use the `SEQUENCE` parameter to capture sequence values from the transaction log. Currently, Oracle GoldenGate supports sequences for the Oracle database.

---

**Note:** DDL support for sequences (`CREATE`, `ALTER`, `DROP`, `RENAME`) is compatible with, but not required for, replicating sequence values. To replicate just sequence values, you *do not* need to install the Oracle GoldenGate DDL support environment. You can just use the `SEQUENCE` parameter.

---

Oracle GoldenGate ensures that the values of a target sequence are:

- higher than the source values if the increment interval is positive
- lower than the source values if the increment interval is negative

Depending on the increment direction, Replicat applies one of the following formulas as a test when it performs an insert:

\[
\text{source\_highwater\_value} + (\text{source\_cache\_size} \times \text{source\_increment\_size}) = \text{target\_highwater\_value}
\]

Or...

\[
\text{source\_highwater\_value} + (\text{source\_cache\_size} \times \text{source\_increment\_size}) \geq \text{target\_highwater\_value}
\]

If the formula evaluates to `FALSE`, the target sequence is updated to be higher than the source value (if sequences are incremented) or lower than the source value (if sequences are decremented). The target must always be ahead of, or equal to, the expression in the parentheses in the formula. For example, if the source high water value is 40, and `CACHE` is 20, the target high water value should be at least 60:

\[40 + (20*1) < 60\]

If the target high water value is less than 80, Oracle GoldenGate updates the sequence to increase the high water value, so that the target remains ahead of the source. To get the current high water value, perform this query:

```
SELECT last_number FROM all_sequences WHERE sequence_owner=upper('SEQUENCEOWNER')
AND sequence_name=upper('SEQUENCENAME');
```

**Supported Processing Modes**

The processing modes that support the capture of sequences are as follows:

- Oracle GoldenGate supports sequences in an active-passive high-availability configuration. Oracle GoldenGate does not support the replication of sequence values in an active-active configuration. An active-passive configuration includes a primary Extract, a data pump, and a Replicat on both servers, but the processes are active in only one direction. The Extract process on the failover server must be inactive, which includes not capturing sequences. See the *Administering Oracle*
**Oracle GoldenGate Parameters**

**3-267**

---

*GoldenGate for Windows and UNIX* for more information about how to configure Oracle GoldenGate for high-availability.

- If using `SEQUENCE` for a primary Extract that writes to a data pump, you must also use an identical `SEQUENCE` parameter in the data pump, whether the data pump is in `PASSTHRU` or `NOPASSTHRU` mode. However, if the `DDL` parameter is being used to propagate DDL operations (for sequences or any other objects) through the same data pump, the data pump must operate in `PASSTHRU` mode.

- Oracle GoldenGate initial load methods that contain the `SOURCEISTABLE` parameter, either as an Extract parameter or within `ADD EXTRACT`, do not support the replication of sequence values.

### Guidelines for Using `SEQUENCE`

- The cache size and the increment interval of the source and target sequences must be identical.

- The cache can be any size, including 0 (`NOCACHE`).

- The sequence can be set to cycle or not cycle, but the source and target databases must be set the same way.

- To add `SEQUENCE` to a configuration in which DDL support is enabled, you must re-install the Oracle GoldenGate DDL objects in `INITIALSETUP` mode.

### Error Handling

- If Extract cannot resolve a sequence name, it ignores the operation.

- To enable Replicat error handling for sequences, use the `REPERRROR` parameter. This parameter is available as an option in the `MAP` parameter and also as a standalone parameter. `REPERRROR` can detect if a sequence has been dropped on the target and can be used to retry a sequence operation until the sequence is recreated.

- `REPERRROR` does not handle missing objects on startup. Use `DDLERROR` with `IGNOREMISSINGTABLES`.

### Other Important Information

- Gaps are possible in the values of the sequences that Oracle GoldenGate replicates because gaps are inherent, and expected, in the way that sequences are maintained by the database. However, the target values will always be greater than those of the source.

- If Extract is running in single-threaded mode on a RAC system, and if sequences are updated on a node that has lag, it might take more time to capture a sequence. This is normal behavior.

- In a failover, any problem that causes the loss or corruption of data in a transaction log or Oracle GoldenGate trail file will cause the loss of the replicated sequence updates.

- The statistics shown by `SEND EXTRACT` and `SEND REPLICAT` when used with the `REPORT` option will show the sequence operation as an `UPDATE`.

### Default

None
Syntax

SEQUENCE [container.]schema.sequence;

[container.]schema.sequence
Specifies the fully qualified name of the source sequence. Include the name of the pluggable database if the source is an Oracle container database. To specify object names and wildcards correctly, see Administering Oracle GoldenGate for Windows and UNIX.

;
Terminates the SEQUENCE parameter statement.

Example

SEQUENCE hr.employees_seq;
SESSIONCHARSET

Valid For

GLOBALS

Description

Use the SESSIONCHARSET parameter to set the database session character set for all database connections that are initiated by Oracle GoldenGate processes in the local Oracle GoldenGate instance. Processes that log into the database include GGSCI, DEFGEN, Extract, and Replicat.

This parameter supports Sybase, Teradata and MySQL. The database character set for other databases is obtained programmatically.

To display the language information in the process report file when using this option for a Sybase database, make certain that locale.dat is set properly in the Sybase installation directory. If the character set is not found in the supported Sybase database character set, then it is validated against the Oracle GoldenGate supported character set list. The character-set information is displayed with the LOCALE INFORMATION entry in the report output.

The SESSIONCHARSET option of the DBLOGIN command can be used to override this setting for any commands issued in the same GGSCI session. The SESSIONCHARSET option of the SOURCEDB and TARGETDB parameters can be used to override this setting for individual process logins.

Default

Character set of the operating system

Syntax

SESSIONCHARSET character_set

character_set
The database session character set.

Example

SESSIONCHARSET ISO-8859-11
SETENV

Valid For

Extract and Replicat

Description

Use the SETENV parameter to set a value for an environment variable. When Extract or Replicat starts, it uses the specified value instead of the one that is set in the operating system environment. A variable set in the SETENV statement overrides any existing variables set at the operating system level. Use one SETENV statement per variable to be set.

Default

None

Syntax

```
SETENV (  
{environment_variable  
  GGS_CacheRetryCount  
  GGS_CacheRetryDelay}  
= 'value'  
)
```

*environment_variable*

The name of the environment variable to be set.

*'value'*

A value for the specified variable. Enclose the value within single quotes.

**GGS_CacheRetryCount**

(SQL Server) Oracle GoldenGate environment parameter that controls the number of times that Extract tries to read the source transaction log files when they are blocked because of excessive system activity. The default is 10 retries. After trying the specified number of times, Extract abends with an error that begins as follows:

```
GGS ERROR 600 [CFileInfo::Read] Timeout expired after 10 retries with 1000 ms delay waiting to read transaction log or backup files.
```

If you continue to see timeout messages in the report file or error log, increase this parameter to allow more retries.

**GGS_CacheRetryDelay**

(SQL Server) Oracle GoldenGate environment parameter that controls the number of milliseconds that Extract waits before trying again to read the transaction logs when the previous attempt has failed. The default is 1000 milliseconds delay.

Examples

**Example 1**

Using separate SETENV statements allows a single instance of Oracle GoldenGate to connect to multiple Oracle database instances without having to change environment
settings. The following parameter statements set a value for ORACLE_HOME and ORACLE_SID.

```bash
SETENV (ORACLE_HOME = '/home/oracle/ora9/product')
SETENV (ORACLE_SID = 'ora9')
```

**Example 2**

The following parameter statements set values for Oracle GoldenGate in a SQL Server environment where Extract tries to read the transaction log for a maximum of 20 times before abending, with a delay of 3000 milliseconds between tries.

```bash
SETENV (GGS_CacheRetryCount = 20)
SETENV (GGS_CacheRetryDelay = 3000)
```
SHOWSYNTAX

Valid For

Replicat

Description

Use the SHOWSYNTAX parameter to start an interactive session where you can view each Replicat SQL statement before it is applied. Viewing SQL statements that failed may help you diagnose the cause of the problem. For example, you could find out that the WHERE clause is using a non-indexed column.

As long as a data type can be applied with dynamic SQL and the column data is bound with a SQL statement, Replicat shows some or all of the data in string form, hexadecimal form, or as a data identifier, depending on the data type. By default, Replicat does not show LOB data or other data types that are treated as a LOB by the database or by Oracle GoldenGate, whether or not the data is bound in SQL. Examples are LOB, XML, and UDT data types. Instead, Replicat shows a data identifier, for example "<LOB data>". To display this type of data, specify the INCLUDELOB option of SHOWSYNTAX. If the column data is not bound in a SQL statement, Replicat does not show the data even when INCLUDELOB is used.

If CHAR/VARCHAR/CLOB or NCHAR/NVARCHAR/NCLOB character data has an unprintable character (U+0000 to U+001F), the character is escaped and displayed in \xx form, where xx is a decimal value that ranges from 00 to 31.

The first time that you use SHOWSYNTAX, request guidance from Oracle Support. It is a debugging parameter and can cause unwanted results if used improperly. It requires manual intervention, which suspends automated processing and can cause backlogs and latency. Use SHOWSYNTAX in a test environment. Create duplicates of your Replicat groups and target tables so that the production environment is not affected.

SHOWSYNTAX is not supported for a coordinated Replicat group.

If used for an integrated Replicat group, sqltrace is enabled for the associated database apply process.

If you capture XML column data using Integrated Extract, the column is captured as updated column even if you do not update the column. As a result of this behavior, SHOWSYNTAX shows the XML column as updated column. However, if you capture the table using Classic Extract, the XML column does not appear in the SHOWSYNTAX SQL statement if the column is not part of the update.

To use SHOWSYNTAX, Replicat must be started from the command shell of the operating system. Do not use SHOWSYNTAX if Replicat is started through GGSCI.

BATCHSQL processing is suspended when SHOWSYNTAX is running. BATCHSQL mode is resumed when Replicat is re-started without SHOWSYNTAX.

To use SHOWSYNTAX, do the following:

1. From the Oracle GoldenGate home directory, start Replicat from the command shell of the operating system using the following syntax. This syntax eliminates the reportfile option and directs the output to the screen.

   
   replicat paramfile dirprm/Replicat_name.prm

2. The first SQL statement is displayed with some prompts.
Choose **Keep Displaying** (the default) to execute the current statement and display the next one.

Choose **Stop Display** to resume normal processing and stop printing SQL statements to screen.

3. When finished viewing syntax, remove **SHOWSYNTAX** from the parameter file.

**Default**

None

**Syntax**

```
SHOWSYNTAX [APPLY | NOAPPLY] [INCLUDELOB [max_bytes | ALL]]
```

**APPLY | NOAPPLY**

Controls whether or not Replicat applies the data that is displayed with **SHOWSYNTAX** to the target database. The default is **APPLY** (apply the data to the target database). **NOAPPLY** prevents the application of the data to the target and does not write the records to the discard file.

**INCLUDELOB [max_bytes] | ALL**

Includes LOB, XML, and UDT data in the **SHOWSYNTAX** output. Without this option, only a data identifier is displayed, such as "<LOB data>.

**max_bytes**

Specifies the maximum length of LOB, XML, or UDT data that is displayed. Valid units are K, M, or G. The default is to display the first 2K bytes.

**ALL**

Displays LOB data in its entirety.

**Example**

```
SHOWSYNTAX INCLUDELOB 1M
```
SOCKSProxy

Valid For

Extract

Description

Use the SOCKSProxy parameter to replicate information using a SOCKS5 proxy server creating a tunnel for TCP communication between a source Extract and a target process. The connection is initiated in the source side. You must specify the proxy address. Optionally you can specify the port or the default for SOCKS protocol will be used. If a credential store alias is specified, Oracle GoldenGate will use that information to authenticate with the proxy server. This is an option for RMTHOST parameter.

If there is no credential store information, no authentication with the proxy is performed.

Default

The default value for port is 1080.

Syntax

SOCKSProxy {host_name | IP address} [:port] [PROXYCSALIAS credential_store_alias [PROXYCSDOMAIN credential_store_domain]]

- **host_name | IP address**: Use for an alias Extract. Specifies the DNS host name or IP address of the proxy server. You can use either one to define the host though you must use the IP address if your DNS server is unreachable. If you are using an IP address, use either an IPv6 or IPv4 mapped address, depending on the stack of the destination system.

- **port**: (Optional) Specifies the port on the remote system where the proxy server accepts connections.

- **PROXYCSALIAS credential_store_alias**: Specifies the credential store alias that resolves to the username and password used to authenticate with the proxy server.

- **PROXYCSDOMAIN credential_store_domain**: (Optional) Specifies the credential store domain used together with the alias.

Example

RMTHOST lc01abc, MGRPORT 7809, SOCKSProxy 192.111.82.180:3128 PROXYCSALIAS proxyAlias PROXYCSDOMAIN support
SOURCECATALOG

Valid For

Extract and Replicat

Description

Use the SOURCECATALOG parameter to specify one of the following for subsequent TABLE or MAP statements that contain two-part names, where three-part object names are required to fully identify an object:

- a default source Oracle pluggable database (PDB)
- a default source SQL/MX user catalog

This parameter provides an efficient alternative to specifying the full three-part object name (container.schema.object or catalog.schema.object) when specifying source objects from an Oracle consolidated database or a SQL/MX database. Only the two-part name (schema.object) need be specified in subsequent TABLE or MAP statements when SOURCECATALOG is used. You can use multiple instances of SOURCECATALOG to specify different default containers or catalogs for different sets of TABLE statements (or SEQUENCE statements, if Oracle).

Three-part name specifications encountered after SOURCECATALOG override the SOURCECATALOG specification in a TABLE statement, MAP statement, or other parameter that takes object names as input.

Default

None

Syntax

SOURCECATALOG {container | catalog}

container
The name of an Oracle pluggable database that contains the specified objects in the TABLE of MAP statement.

catalog
The name of a SQL/MX user catalog that contains the specified objects in the TABLE or MAP statement.

Example

In the following example, SOURCECATALOG is used to specify three different source Oracle PDBs in an Extract parameter file.

```
SOURCECATALOG FINANCE
TABLE SAP.*;
TABLE REPORTS.*;
SOURCECATALOG HR
TABLE SIEBEL.*;
TABLE REPORTS.*;
SOURCECATALOG MFG
TABLE CUSTOMER.ORDERS;
TABLE REPORTS.*;
TABLE HQ.LOCATIONS.*;
```
In this example, Extract captures the following:

- All tables in the \texttt{SAP} and \texttt{REPORTS} schemas in the \texttt{FINANCE PDB}.
- All tables in the \texttt{SIEBEL} and \texttt{REPORTS} schemas in the \texttt{HR PDB}.
- All tables in the \texttt{CUSTOMER} and \texttt{REPORTS} schemas in the \texttt{MFG PDB}.
- For the last \texttt{TABLE} statement, Extract captures all tables in the \texttt{LOCATIONS} schema in the \texttt{HQ PDB}. This statement is a fully qualified three-part name and overrides the previous \texttt{SOURCECATALOG} specification.
### SOURCECHARSET

#### Valid For
Replicat

#### Description
Use the `SOURCECHARSET` parameter to control the conversion of data from the source character set to the target character set by Replicat. Replicat converts character sets by default for versions 11.2.1 and later, but you may need to intervene in the following cases:

- To enable accurate conversion of data written by an Extract version earlier than 11.2.1. Extract versions prior to version 11.2.1 do not write information about the source character set to the trail, so the information must be supplied to Replicat directly. Extract versions 11.2.1 and later write information about the source character set to the trail for use by Replicat, and any `SOURCECHARSET` specification is ignored.

- To prevent conversion to the target character set. Use `SOURCECHARSET` with the `PASSTHRU` option to prevent the conversion of character sets. `PASSTHRU` ensures data integrity in cases where conversion would cause data to be misrepresented on the target. An example use case is when source applications write binary data to character columns and it must remain in binary form on the target. You also can use `PASSTHRU` to avoid the overhead of conversion if you are certain that all of the data is ASCII and there are no ASCII-incompatible characters in character columns.

- To override the source database character set in the trail file. Use `SOURCECHARSET` with the `OVERRIDE` option to specify the character set you want to use. An example use case is migrating a database to UNICODE or particular character set database from garbage in, garbage out type of non-character set aware database by ignoring the source database character set.

Replicat issues a warning message when it uses the `SOURCECHARSET` character set.

Use the `REPLACEBADCHAR` parameter to handle validation errors where there are invalid characters in the source data or the target character set does not support a source character. It provides options to abend on these errors, skip the record that caused the error, or specify a substitute value for the character.

#### Default
None

#### Syntax

```
SOURCECHARSET {source_charset | PASSTHRU | OVERRIDE} [DB22OS]
```

- **source_charset**
  Specifies the source character set for data that is written by an Extract version that is earlier than 11.2.1. Replicat uses the specified character set when converting character-type columns to the target character set.

  For `source_charset`, specify the appropriate character-set identifier that represents the source database. For a list of supported character sets, see *Administering Oracle GoldenGate for Windows and UNIX*.  

```
For Oracle, if \texttt{SOURCECHARSET} is not specified but there is an \texttt{NLS_LANG} environment variable on the target, Replicat uses the \texttt{NLS_LANG} value as the source database character set. If neither \texttt{SOURCECHARSET} nor \texttt{NLS_LANG} is present, Replicat abends to prevent possible data corruption.

**PASSTHRU**

Forces Replicat to apply the data without converting the character set. Character set differences are ignored as follows:

- If the database is Oracle, the data is applied the way it is stored in the trail.
- If the database is other than Oracle, the data is applied as binary data if the database supports a bind as binary data. Otherwise, the data is applied as-is.

\texttt{PASSTHRU} is not compatible with the \texttt{BULKLOAD} parameter (direct-bulk load).

If \texttt{PASSTHRU} is specified and a mapping between \texttt{CHAR/VARCHAR/CLOB} and \texttt{NCHAR/NVARCHAR/NCLOB} exists in the \texttt{MAP} statement, Replicat abends.

If any Oracle GoldenGate column-mapping functions are used for character-based columns when \texttt{PASSTHRU} mode is specified, Replicat issues a warning message and converts the results of those functions to the target database character set before mapping them to the target column.

\texttt{PASSTHRU} should only be used if you are certain the source and target character sets are compatible. If you are not sure whether \texttt{PASSTHRU} is appropriate in your environment, contact Oracle Support before using it.

**OVERRIDE**

Forces Replicat to use the specified character set thus overriding the source database character set in the trail file. This option overrides character type column character set except in the following cases:

- The character set is overridden by the \texttt{CHARSET} and \texttt{COLCHARSET} parameters.
- Use of \texttt{NCHAR, NVARCHAR, NCLOB} data types.
- The database overrides the column character set explicitly to a set other than the database character set.

**DB2ZOS**

Valid for DB2 on z/OS.

Required if the version of a trail that contains DB2 data from the z/OS platform is Oracle GoldenGate 9.0 or 9.5. This parameter ensures that Replicat recognizes that the data is from DB2 on z/OS, which permits a mix of ASCII and EBCDIC character formats.

### Examples

**Example 1**

\texttt{SOURCECHARSET ISO-8859-9}

**Example 2**

\texttt{SOURCECHARSET PASSTHRU}

**Example 3**

\texttt{SOURCECHARSET JA16EUC}
Example 4

SOURCECHARSET OVERRIDE WE8ISO8859P15
**SOURCEDB**

**Valid For**
Manager, Extract, DEFGEN

**Description**
Use the `SOURCEDB` parameter for databases or data sets that require a data source name or identifier to be specified explicitly as part of the connection information. This option is required to identify one of the following:

- The source login database for heterogenous databases.
- The data source name (DSN) for supported databases that use ODBC
- The source SQL/MX catalog, valid when Extract will process data from only one catalog in the SQL/MX database
- The default DB2 for i database.

Tables specified in `TABLE` statements that follow `SOURCEDB` are assumed to be from the specified data source.

You might need to use the `USERID` or `USERIDALIAS` parameter in the `SOURCEDB` parameter statement, depending on the authentication that is required for the data source.

For databases that allow authentication at the operating-system level, you can specify `SOURCEDB` without `USERID` or `USERIDALIAS`.

For Manager, use `SOURCEDB` only when using Oracle GoldenGate parameters that cause Manager to interact with a source database, such as `PURGEOLDEXTRACTS`. You can use `SOURCEDB` for Manager on the source or target database.

For DB2 LUW, the `SOURCEDB` statement must refer to the database by its real name, rather than by any alias.

See `USERID` or `USERIDALIAS` for more information.

**Default**
None

**Syntax**

```
SOURCEDB data_source[, SESSIONCHARSET character_set]
```

*data_source*
The name of the database, catalog, or data source name as applicable for the database.

For MySQL databases, you can use the format of `SOURCEDB database_name@host_name` to avoid connection issues caused by the incorrect configuration of `localhost` in the local hosts file. If running MySQL on a port other than the default of 3306, you must specify the port number in the connect string: `SOURCEDB database_name@host_name:port`.

*SESSIONCHARSET character_set*
Supports Sybase, Teradata and MySQL. Sets the database session character set for the process login session. This parameter overrides any `SESSIONCHARSET` that is specified in the `GLOBALS` file.
To display the language information in the process report file when using this option for a Sybase database, make certain that `locale.dat` is set properly in the Sybase installation directory. If the character set is not found in the supported Sybase database character set, then it is validated against the Oracle GoldenGate supported character set list. The character-set information is displayed with the `LOCALE INFORMATION` entry in the report output.

**Examples**

**Example 1**
This example shows `SOURCEDB` without the `USERIDALIAS` parameter.

```plaintext
SOURCEDB mydb
```

**Example 2**
This example shows `SOURCEDB` with the `USERIDALIAS` parameter.

```plaintext
SOURCEDB mydb, USERIDALIAS tiger1
```
Valid For

Extract data pump and Replicat

Description

Use the SOURCEDEFS parameter to specify the name of a file that contains definitions of source tables or files. Source definitions are required when using Oracle GoldenGate to replicate data between heterogeneous source and targets. Use SOURCEDEFS for one or more of the following processes, depending on your Oracle GoldenGate configuration:

- A Replicat process on the target system
- A data pump on a source or intermediary system.

To generate the source-definitions file, use the DEFGEN utility. Transfer the file to the intermediary or target system before starting a data pump or Replicat.

You can have multiple SOURCEDEFS statements in the parameter file if more than one source-definitions file will be used, for example if each SOURCEDEFS file holds the definitions for a distinct application.

See "ASSUMETARGETDEFS" on page 3-22 for related information. Do not use SOURCEDEFS and ASSUMETARGETDEFS in the same parameter file.

See Administering Oracle GoldenGate for Windows and UNIX for more information about using data-definitions files.

Default

None

Syntax

`SOURCEDEFS file_name`

`file_name`
The relative or fully qualified name of the file containing the source data definitions.

Examples

**Example 1**

`SOURCEDEFS dirdef\tcust.def`

**Example 2**

`SOURCEDEFS /ggs/dirdef/source_defs`
SOURCEISTABLE

Valid For

Extract

Description

Use the SOURCEISTABLE parameter to extract complete records directly from source tables in preparation for loading them into another table or file. SOURCEISTABLE extracts all column data specified within a TABLE statement.

This parameter applies to the following initial load methods:

■ Loading data from file to Replicat.
■ Loading data from file to database utility.

Do not use this parameter for the following initial load methods:

■ An Oracle GoldenGate direct load, where Extract sends load data directly to the Replicat process without use of a file.
■ An Oracle GoldenGate direct bulk load to SQL*Loader.

For those processes, SOURCEISTABLE is specified as an ADD EXTRACT argument instead of being used in the parameter file.

When used, SOURCEISTABLE must be the first parameter statement in the Extract parameter file.

To use SOURCEISTABLE, disable DDL extraction and replication by omitting the DDL parameter from the Extract and Replicat parameter files. See "DDL" on page 3-77 for more information.

See Administering Oracle GoldenGate for Windows and UNIX for more information about configuring initial data loads.

Default

None

Syntax

SOURCEISTABLE
SOURCETIMEZONE

Valid For

Replicat

Description

Use the SOURCETIMEZONE parameter to specify the time zone of the source database. Use this parameter for one of the following purposes:

- To override the source time zone that is stored in the trail. By default, Replicat sets its session to the specified time zone, in both region ID and offset value. This option applies to Oracle GoldenGate versions 12.1.2 or later, where the source time zone is written to the trail by Extract. Replicat will set its session to the specified time zone.

- To supply the time zone of the source database when the trail is written by an Extract version that is older than 12.1.2. In these versions, Extract does not write the source time zone to the trail, so it must be supplied by this parameter. Replicat will set its session to the specified time zone.

To disable the default use of the source time zone by Replicat, use the PRESERVETARGETTIMEZONE parameter in the Replicat parameter file. See PRESERVETARGETTIMEZONE for more information.

Default

None

Syntax

SOURCETIMEZONE time_zone

**time_zone**
The time zone of the source database as output by the database for DATE, TIME and TIMESTAMP data types. It can be specified in the following ways.

- As a region ID that is valid in the IANA Time Zone Database (tz database). (A region ID is also known as an Olson time zone ID). An adjustment for Daylight Saving Time can be performed by the target database, if supported.

- As an offset from UTC.

Examples

The following examples show different ways to specify SOURCETIMEZONE.

- These examples specify a region ID.

  SOURCETIMEZONE America/New_York

  SOURCETIMEZONE US/Pacific

  SOURCETIMEZONE Japan

  SOURCETIMEZONE UTC

  SOURCETIMEZONE Pacific/Guam
These examples specify an offset from UTC.

SOURCETIMEZONE +09:00

SOURCETIMEZONE -04:30
**SPACESTONULL | NOSPACESTONULL**

**Valid For**

Replicat on Oracle Database only

**Description**

Use the **SPACESTONULL** and **NOSPACESTONULL** parameters to control whether or not a source column that contains only spaces is converted to NULL in the target column. **SPACESTONULL** converts spaces to NULL if the target column accepts NULL values. **NOSPACESTONULL** converts spaces to a single space character in the target column.

This parameter is applicable to the following two scenarios:
- A source column that contains only spaces
- A source column is empty, such as empty CHAR/VARCHAR column data from DB2

Oracle does not distinguish empty and NULL columns though other databases do so you should consult your database documentation to determine how these types of columns.

The parameters are table specific. One parameter applies to all subsequent **MAP** statements, until the other parameter is encountered.

Because you can selectively enable or disable these parameters between **MAP** statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the **SPACESTONULL** threads in one set of **MAP** statements, and specify the **NOSPACESTONULL** threads in a different set of **MAP** statements.

**Default**

**NOSPACESTONULL**

**Syntax**

**SPACESTONULL | NOSPACESTONULL**

**Example**

This example shows how you can apply **SPACESTONULL** and **NOSPACESTONULL** selectively to different **MAP** statements, each of which represents a different thread of a coordinated Replicat.

**SPACESTONULL**

**MAP** sales.cust, **TARGET** sales.cust, **THREAD** (1);
**MAP** sales.ord, **TARGET** sales.ord, **THREAD** (2);
**NOSPACESTONULL**

**MAP** sales.loc, **TARGET** sales.loc, **THREAD** (3);
SPECIALRUN

Valid For

Replicat

Description

Use the SPECIALRUN parameter in a Replicat parameter file for a one-time processing run to direct Replicat not to create checkpoints. A one-time run has a beginning and an end, so checkpoints are not needed. Use SPECIALRUN for certain initial data load methods.

When Replicat is in SPECIALRUN mode, do not start it with the START REPLICAT command in GGSCI. It is started automatically during the initial load.

SPECIALRUN requires the use of the END parameter. Either REPLICAT or SPECIALRUN is required in the Replicat parameter file. See "REPLICAT" on page 3-239 for more information.

Default

None

Syntax

SPECIALRUN
SQLDUPERR

Valid For
Replicat

Description
Use the SQLDUPERR parameter to specify the numeric error code returned by the target database when a duplicate row is encountered. A duplicate-record error indicates that an INSERT operation was attempted with a primary key that matches the key of an existing record in the database.

You must use SQLDUPERR when you specify the special handling of duplicate records with the OVERRIDEDUPS parameter. See "OVERRIDEDUPS | NOOVERRIDEDUPS" on page 3-208 for more information.

Default
None

Syntax

SQLDUPERR error_number

error_number
The numeric error code to return for duplicate records.

Example

SQLDUPERR -2601
**SQLEXEC**

**Valid For**

Extract and Replicat

**Description**

Use the `SQLEXEC` parameter to execute a stored procedure, query, or database command within the context of Oracle GoldenGate processing. `SQLEXEC` enables Oracle GoldenGate to communicate directly with the database to perform any work that is supported by the database. This work can be part of the synchronization process, such as retrieving values for column conversion, or it can be independent of extracting or replicating data, such as executing a stored procedure that executes an action within the database.

`SQLEXEC` works as follows:

- As a standalone statement at the root level of a parameter file to execute a SQL stored procedure or query or to execute a database command. As a standalone statement, `SQLEXEC` executes independently of a `TABLE` or `MAP` statement during Oracle GoldenGate processing. When used in a standalone `SQLEXEC` parameter, a query or procedure cannot include parameters. See "Standalone SQLEXEC" on page 3-289.

- As part of a `TABLE` or `MAP` parameter to execute a stored procedure or query with or without parameters. When used with parameters, the procedure or query that is executed can accept input parameters from source or target rows and pass output parameters. See "SQLEXEC in a TABLE or MAP Parameter" on page 3-291.

---

**Caution:** Use caution when executing `SQLEXEC` procedures against the database, especially against the production database. Any changes that are committed by the procedure can result in overwriting existing data.

---

**Standalone SQLEXEC**

A standalone `SQLEXEC` parameter is one that is used at the root level of a parameter file and acts independently of a `TABLE` or `MAP` parameter. The following are guidelines for using a standalone `SQLEXEC` parameter.

- A standalone `SQLEXEC` statement executes in the order in which it appears in the parameter file relative to other parameters.

- A `SQLEXEC` procedure or query must contain all exception handling.

- A query or procedure must be structured correctly when executing a `SQLEXEC` statement, with legal SQL syntax for the database; otherwise Replicat will abend, regardless of any error-handling rules that are in place. Refer to the SQL reference guide provided by the database vendor for permissible SQL syntax.

- A database credential for the Oracle GoldenGate user must precede the `SQLEXEC` clause. For Extract, use the `SOURCEDB` and `USERID` or `USERIDALIAS` parameters as appropriate for the database. For Replicat, use the `TARGETDB` and `USERID` or `USERIDALIAS` parameters, as appropriate.
The database credential that the Oracle GoldenGate process uses is the one that executes the SQL. This credential must have the privilege to execute commands and stored procedures and call database-supplied procedures.

A standalone SQLEXEC statement cannot be used to get input parameters from records or pass output parameters. You can use stored procedures and queries with parameters by using a SQLEXEC statement within a TABLE or MAP statement. See "SQLEXEC in a TABLE or MAP Parameter" on page 3-291.

All objects affected by a standalone SQLEXEC statement must exist before the Oracle GoldenGate processes start. Because of this, DDL support must be disabled for those objects; otherwise, DDL operations could change the structure of, or delete an object, before the SQLEXEC procedure or query executes on it.

Object names must be fully qualified in their two-part or three-part name format.

For DB2 on z/OS, Oracle GoldenGate uses the ODBC SQLExecDirect function to execute a SQL statement dynamically. ODBC prepares the SQL statement every time that it is executed, at a specified interval. To support this function, the connected database server must be configured to prepare SQL dynamically. See the DB2 for z/OS documentation for more information.

### Getting More Information about Using Standalone SQLEXEC

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about how to use SQLEXEC.

### Syntax for Standalone SQLEXEC

```
SQLEXEC
{ 'call procedure_name ()' | 'SQL_query' | 'database_command' }
[EVERY n { SECONDS | MINUTES | HOURS | DAYS }]
[ONEXIT]
[, THREADS ( threadID [, threadID] [, ...] [, thread_range [, thread_range] [, ...] ] ) ]
```

**'call procedure_name ()'**

Specifies the name of a stored procedure to execute. Enclose the statement within single quotes. The `call` keyword is required. The following is an example of how to execute a procedure with standalone SQLEXEC:

```
SQLEXEC 'call prc_job_count ()'
```

**'SQL_query'**

Specifies the name of a query to execute. Enclose the query within single quotes. Specify case-sensitive object names in the same format required by the database. The following is an example of how to execute a query with standalone SQLEXEC:

```
SQLEXEC ' select x from dual '
```

For a multi-line query, use the single quotes on each line. For best results, type a space after each begin quote and before each end quote (or at least before each end quote).

**'database_command'**

Executes a database command. The following is an example of how to execute a database command with standalone SQLEXEC:

```
SQLEXEC 'SET TRIGGERS OFF'
```

**EVERY n { SECONDS | MINUTES | HOURS | DAYS }**

Causes a standalone stored procedure or query to execute at a defined interval, for example:
**SQLEXEC**

SQLEXEC 'call prc_job_count ()' EVERY 30 SECONDS

The interval must be a whole, positive integer.

**ONEXIT**

Executes the SQL when the Extract or Replicat process stops gracefully, for example:

```sql
SQLEXEC 'call prc_job_count ()' ONEXIT
```

**THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])**

Executes SQLEXEC only for the specified thread or threads of a coordinated Replicat.

- `threadID[, threadID][, ...]`
  - Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

- `[, thread_range[, thread_range][, ...]]`
  - Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

If no `THREADS` clause is used, the SQL is executed by all of the threads that were configured for this Replicat group by the `ADD REPLICAT` command. However, if the SQL satisfies the criteria for a barrier transaction, the entire SQLEXEC statement is processed by thread 0 regardless of the actual thread mapping.

**SQLEXEC in a TABLE or MAP Parameter**

A SQLEXEC parameter in a TABLE or MAP parameter can be used to execute a stored procedure or query that does or does not accept parameters. The following are SQLEXEC dependencies and restrictions when used in a MAP or TABLE statement:

- The SQL is executed by the database user under which the Oracle GoldenGate process is running. This user must have the privilege to execute stored procedures and call database-supplied procedures.

- A query or procedure must be structured correctly when executing a SQLEXEC statement. If Replicat encounters a problem with the query or procedure, the process abends immediately, despite any error-handling rules that are in place. Refer to the SQL reference guide provided by the database vendor for permissible SQL syntax.

- The COMMIT operation of a Replicat transaction to the target database also commits any DML changes that are made in a SQLEXEC statement within the boundary of the original source transaction. This is not true for Extract, because Extract does not perform SQL transactions. When using SQLEXEC for Extract, you can either enable implicit commits or execute an explicit commit within the SQLEXEC procedure.

- Specify literals in single quotes. Specify case-sensitive object names the same way they are specified in the database.

- Do not use SQLEXEC to change the value of a primary key column. The primary key value is passed from Extract to Replicat. Without it, Replicat operations cannot be completed. If primary key values must be changed with SQLEXEC, you may be able to avoid errors by mapping the original key value to another column and then
defining that column as a substitute key with the `KEYCOLS` option of the `TABLE` and `MAP` parameters.

- For DB2 on z/OS, Oracle GoldenGate uses the ODBC `SQLExecDirect` function to execute a SQL statement dynamically. ODBC prepares the SQL statement every time that it is executed, at a specified interval. To support this function, the connected database server must be configured to prepare SQL dynamically. See the DB2 for z/OS documentation for more information.

- When using Oracle GoldenGate to replicate DDL, all objects that are affected by a stored procedure or query must exist with the correct structures prior to the execution of the SQL. Consequently, DDL on these objects that affects structure (such as `CREATE` or `ALTER`) must execute before the `SQLEXEC` executes.

- All object names in a `SQLEXEC` statement must be fully qualified with their two-part or three-part names, as appropriate for the database.

- Do not use `SQLEXEC` for tables being processed in pass-through mode by a data-pump Extract group.

- The following data types are supported by `SQLEXEC` for input and output parameters.
  - Numeric data types
  - Date data types
  - Character data types

- When executed by a coordinated Replicat, `SQLEXEC` is executed by the thread or threads that are specified with the `THREAD` or `THREADRANGE` option of the `MAP` statement. However, if the `SQLEXEC` is specified in a `MAP` parameter that contains the `COORDINATED` keyword, it is executed as a barrier transaction automatically by the thread with the lowest ID number, regardless of the actual thread mapping.

### Getting More Information about Using `SQLEXEC` in `TABLE` and `MAP`

For more information about how to use `SQLEXEC`, see *Administering Oracle GoldenGate for Windows and UNIX*.

For more information about `TABLE` and `MAP`, see "TABLE | MAP" on page 3-305.

### Syntax for `SQLEXEC` in `TABLE` or `MAP`

```sql
SQLEXEC ( {SPNAME procedure_name[, ID logical_name] | 
ID logical_name, QUERY ' SQL_query ')}
{, PARAMS [OPTIONAL | REQUIRED] parameter_name = {source_column | OGG_function} | 
NOPARAMS}
[, AFTERFILTER | BEFOREFILTER]
[, ALLPARAMS [OPTIONAL | REQUIRED]}]
[, ERROR {IGNORE | REPORT | RAISE | FINAL | FATAL}]
[, EXEC {MAP | ONCE | TRANSACTION | SOURCEROW}]
[, MAXVARCHARLEN bytes]
[, PARAMBUFSIZE bytes]
[, TRACEx]
[, ...]
)
```

**SPNAME procedure_name[, ID logical_name]**

Executes a stored procedure.

---

3-292  Reference for Oracle GoldenGate for Windows and UNIX
**SPNAME procedure_name**  
Specifies the name of the procedure to execute.

The following example shows a single execution of a stored procedure named lookup. In this case, the actual name of the procedure is used. A logical name is not needed.

```sql
SQL_EXEC (SPNAME lookup), PARAMS (param1 = srccol)), &
COLMAP (targcol = lookup.param1);
```

**ID logical_name**  
Defines an optional logical name for the procedure. For example, logical names for a procedure named lookup might be lookup1, lookup2, and so forth. Use this option to execute the procedure multiple times within a MAP statement. A procedure can execute up to 20 times per MAP statement. ID is not required when executing a procedure once.

The following example shows the use of the ID option to enable multiple executions of a stored procedure that gets values from a lookup table. The values are mapped to target columns.

```sql
SQL_EXEC (SPNAME lookup, ID lookup1, &
  PARAMS (long_name = current_residence_state)), &
SQL_EXEC (SPNAME lookup, ID lookup2, &
  PARAMS (long_name = birth_state)), &
COLMAP (custid = custid, current_residence_state_long = lookup1.long_name, &
birth_state_long = lookup2.long_name);
```

**ID logical_name, QUERY ' SQL_query '**  
Executes a query.

**ID logical_name**  
Defines a logical name for the query. A logical name is required in order to extract values from the query results. ID logical_name references the column values returned by the query.

**QUERY ' SQL_query '**  
Specifies the SQL query syntax to execute against the database. The query can either return results with a SELECT statement or execute an INSERT, UPDATE, or DELETE statement. A SELECT statement should only return one row. If multiple rows are returned, only the first row is processed. Do not specify an INTO ... clause for any SELECT statements.

The query must be valid, standard query language for the database against which it is being executed. Most queries require placeholders for input parameters. How parameters are specified within the query depends on the database type, as follows:

- For Oracle, input parameters are specified by using a colon (:) followed by the parameter name, as in the following example.

  ```sql
  'SELECT NAME FROM ACCOUNT WHERE SSN = :SSN AND ACCOUNT = :ACCT'
  ```

- For other databases, input parameters are specified by using a question mark, as in the following example.

  ```sql
  'SELECT NAME FROM ACCOUNT WHERE SSN = ? AND ACCOUNT = ?'
  ```

The query must be contained on one line, within single quotes. Quotation marks are not required around a parameter name for any database.
The following examples illustrate the use of a SQLEXEC query for Oracle and SQL Server queries, respectively.

Oracle example:

```sql
MAP sales.account, TARGET sales.newacct, &
SQLEXEC (ID lookup, &
QUERY 'select desc_col into desc_param from lookup_table &
where code_col = :code_param', &
PARAMS (code_param = account_code)), &
COLMAP (newacct_id = account_id, newacct_val = lookup.desc_param);
```

SQL Server example:

```sql
MAP sales.account, TARGET sales.newacct, &
SQLEXEC (ID lookup, &
QUERY 'select desc_col into desc_param from lookup_table &
where code_col = ?', &
PARAMS (p1 = account_code)), &
COLMAP (newacct_id = account_id, &
newacct_val = lookup.desc_param);
```

**PARAMS [OPTIONAL | REQUIRED] parameter_name = (source_column | OGG_function) | NOPARAMS**

Defines whether or not the procedure or query accepts parameters and, if yes, maps the parameters to the input source. Either a PARAMS clause or NOPARAMS must be used.

**OPTIONAL | REQUIRED**

Determines whether or not the procedure or query executes when parameter values are missing.

OPTIONAL indicates that a parameter value is not required for the SQL to execute. If a required source column is missing from the database operation, or if a column-conversion function cannot complete successfully because a source column is missing, the SQL executes anyway. OPTIONAL is the default for all databases except Oracle. For Oracle, whether or not a parameter is optional is automatically determined when retrieving the stored procedure definition.

REQUIRED indicates that a parameter value must be present. If the parameter value is not present, the SQL will not be executed.

**parameter_name = (source_column | OGG_function)**

Maps the name of a parameter to a column or function that provides the input. The following data types are supported by SQLEXEC for input and output parameters.

- Numeric data types
- Date data types
- Character data types

**parameter_name** is one of the following:

- For a stored procedure, it is the name of any parameter in the procedure that can accept input.
- For an Oracle query, it is the name of any input parameter in the query excluding the leading colon. For example, `:vemplid` would be specified as `vemplid` in the PARAMS clause. Oracle permits naming an input parameter any logical name.
For a non-Oracle query, it is $P_n$, where $n$ is the number of the parameter within the statement, starting from 1. For example, in a query with two parameters, the parameter_name entries are $p_1$ and $p_2$. Consider whether the database requires the $p$ to be upper or lower case.

**Source column** is the name of a source column that provides the input. By default, if the specified column is not present in the log (because the record only contains the values of columns that were updated) the parameter assumes any default value specified by the procedure or query for the parameter.

**OGG_function** is the name of an Oracle GoldenGate column-conversion function that executes to provide the input. See "Column Conversion Functions" on page 5-1.

To pass output values from the stored procedure or query as input to a **FILTER** or **COLMAP** clause, use the following syntax:

```
{procedure_name | logical_name}.parameter
```

Where:

- **procedure_name** is the actual name of a stored procedure, which must match the value given for **SPNAME** in the **SQLEXEC** statement. Use this argument only if executing a procedure one time during the course of the Oracle GoldenGate run.

- **logical_name** is the logical name specified with the **ID** option of **SQLEXEC**. Use this argument to pass input values from either a query or an instance of a stored procedure when the procedure executes multiple times within a **MAP** statement.

- **parameter** is the name of a parameter or **RETURN_VALUE** if extracting returned values. By default, output values are truncated at 255 bytes per parameter. If output parameters must be longer, use the **MAXVARCHARLEN** option.

**Note:** As an alternative to the preceding syntax, you can use the **@GETVAL** function. See "GETVAL" on page 5-36 for more information.

The following examples apply to a set of Oracle source and target tables and a lookup table. These examples show how parameters for the tables are passed for a single instance of a stored procedure and multiple instances of a stored procedure.

**Source table cust:**

| custid | Number |
|----------------|
| current_residence_state | Char(2) |
| birth_state | Char(2) |

**Target table cust_extended:**

| custid | Number |
|----------------|
| current_residence_state_long | Varchar(30) |
birth_state_long     Varchar(30)

Lookup table state_lookup
abbreviation     Char(2)
long_name        Varchar(30)

The following example shows the use of a stored procedure that executes once to get a value from the lookup table. When processing records from the cust table, Oracle GoldenGate executes the lookup stored procedure before executing the column map. The long_name parameter in the procedure accepts input from the birth_state source column. The value is mapped to the target column birth_state_long in the COLMAP statement.

MAP sales.cust, TARGET sales.cust_extended, &
  SQLEXEC (SPNAME lookup, &
    PARAMS (long_name = birth_state)), &
  COLMAP (custid = custid, &
    birth_state_long = lookup.long_name);

The following example shows the use of the ID option to enable multiple executions of a stored procedure that gets values from a lookup table. The values are mapped to target columns.

MAP sales.cust, TARGET sales.cust_extended, &
  SQLEXEC (SPNAME lookup, &
    PARAMS (long_name = birth_state)), &
  SQLEXEC (SPNAME lookup, ID lookup1, &
    PARAMS (long_name = current_residence_state)), &
  SQLEXEC (SPNAME lookup, ID lookup2, &
    PARAMS (long_name = birth_state)), &
  COLMAP (custid = custid, &
    current_residence_state_long = lookup1.long_name, &
    birth_state_long = lookup2.long_name);

AFTERFILTER | BEFOREFILTER
Use AFTERFILTER and BEFOREFILTER to specify when to execute the stored procedure or query in relation to the FILTER clause of a MAP statement.

AFTERFILTER
Causes the SQL to execute after the FILTER statement. This enables you to skip the overhead of executing the SQL unless the filter is successful. This is the default.

BEFOREFILTER
Causes the SQL to execute before the FILTER statement, so the results can be used in the filter.

The following is an example using BEFOREFILTER.

SQLEXEC (SPNAME check, NOPARAMS, BEFOREFILTER)

ALLPARAMS [OPTIONAL | REQUIRED]
Use ALLPARAMS as a global rule that determines whether or not all of the specified parameters must be present for the stored procedure or query to execute. Rules for individual parameters established within the PARAMS clause override the global rule set with ALLPARAMS.

OPTIONAL
Permits the SQL to execute whether or not all of the parameters are present. This is the default.

REQUIRED
Requires all of the parameters to be present for the SQL to execute.
The following is an example using **OPTIONAL**.

```sql
SQLEXEC (SPNAME lookup,
PARAMS (long_name = birth_state, short_name = state),
ALLPARAMS OPTIONAL)
```

**ERROR** (**IGNORE** | **REPORT** | **RAISE** | **FINAL** | **FATAL**)

Use **ERROR** to define a response to errors associated with the stored procedure or query. Without explicit error handling, the Oracle GoldenGate process abends on errors. Make certain your procedures return errors to the process and specify the responses with **ERROR**.

- **IGNORE**
  Causes Oracle GoldenGate to ignore all errors associated with the stored procedure or query and continue processing. Any resulting parameter extraction results in "column missing" conditions. This is the default.

- **REPORT**
  Ensures that all errors associated with the stored procedure or query are reported to the discard file. The report is useful for tracing the cause of the error. It includes both an error description and the value of the parameters passed to and from the procedure or query. Oracle GoldenGate continues processing after reporting the error.

- **RAISE**
  Handles errors according to rules set by a **REERROR** parameter. Oracle GoldenGate continues processing other stored procedures or queries associated with the current **MAP** statement before processing the error.

- **FINAL**
  Is similar to **RAISE** except that when an error associated with a procedure or query is encountered, remaining stored procedures and queries are bypassed. Error processing is invoked immediately after the error.

- **FATAL**
  Causes Oracle GoldenGate to abend immediately upon encountering an error associated with a procedure or query.

**EXEC** (**MAP** | **ONCE** | **TRANSACTION** | **SOURCEROW**)

Use **EXEC** to control the frequency with which a stored procedure or query in a **MAP** statement executes and how long the results are considered valid, if extracting output parameters.

- **MAP**
  Executes the procedure or query once for each source-target table map for which it is specified. Using **MAP** renders the results invalid for any subsequent maps that have the same source table. **MAP** is the default.

The following example shows the incorrect use of the default of **MAP**. Because **MAP** is the default, it need not be explicitly listed in the **SQLEXEC** statement. In this example, a source table is mapped in separate **MAP** parameters to two different target tables. In this case, the results are valid only for the first mapping. The results of the procedure **lookup** are expired by the time the second **MAP** parameter executes, and the second **MAP** results in a "column missing" condition. To implement this correctly so that each **MAP** returns valid results, **SOURCEROW** should be used.

```sql
MAP sales.src tab, TARGET sales.tar tab, &
```
ONCE
Executes the procedure or query once during the course of the Oracle GoldenGate run, upon the first invocation of the associated MAP statement. The results remain valid for as long as the process remains running.

The following is an example of using ONCE.

```sql
MAP sales.cust, TARGET sales.cust_extended, &
SQLEXEC (SPNAME lookup, PARAMS (long_name = birth_state), EXEC ONCE), &
COLMAP (custid = custid, &
birth_state_long = lookup.long_name);
```

TRANSACTION
Executes the procedure or query once per source transaction. The results remain valid for all operations of the transaction.

The following is an example of using TRANSACTION.

```sql
MAP sales.cust, TARGET sales.cust_extended, &
SQLEXEC (SPNAME lookup, PARAMS (long_name = birth_state), EXEC TRANSACTION), &
COLMAP (custid = custid, &
birth_state_long = lookup.long_name);
```

SOURCEROW
Executes the procedure or query once per source row operation. Use this option when you are synchronizing a source table with more than one target table, so that the results of the procedure or query are invoked for each source-target mapping.

The following is an example of using SOURCEROW. In this case, the second map returns a valid value because the procedure executes on every source row operation.

```sql
MAP sales.srctab, TARGET sales.targtab, &
SQLEXEC (SPNAME lookup, PARAMS (param1 = srccol), EXEC SOURCEROW), &
COLMAP (targcol = lookup.param2);
```

MAXVARCHARLEN bytes
Use MAXVARCHARLEN to specify the maximum byte length allocated for the output value of any parameter in a stored procedure or query. Beyond this maximum, the output values are truncated. The default is 255 bytes without an explicit MAXVARCHARLEN clause. The valid range of values is from 50 to 32767 bytes, except for Oracle TimesTen. The maximum output value for Oracle TimesTen is 2560 bytes.

The following example limits the byte length of output values to 100.

```sql
MAXVARCHARLEN 100
```

PARAMBUFSIZE bytes
Use PARAMBUFSIZE to specify the maximum number of bytes allowed for the memory buffer that stores SQLEXEC parameter information, including both input and output parameters. The default is 10,000 bytes without an explicit PARAMBUFSIZE clause. The valid range of values is from 1000 to 2000000 bytes. Oracle GoldenGate issues a
warning whenever the memory allocated for parameters is within 500 bytes of the maximum.

The following example increases the buffer to 15,000 bytes.

PARAMBUFSIZE 15000

**TRACE {ALL | ERROR}**

Use TRACE to log `SQLEXEC` input and output parameters to the report file.

The following is a sample report file with `SQLEXEC` tracing enabled:

Input parameter values...
LMS_TABLE: INTERACTION_ATTR_VALUES
  KEY1: 2818249
  KEY2: 1
Report File:
From Table MASTER.INTERACTION_ATTR_VALUES to MASTER.INTERACTION_ATTR_VALUES:
  # inserts: 0
  # updates: 0
  # deletes: 0
  # discards: 1

Stored procedure GGS_INTERACTION_ATTR_VALUES:
  attempts: 2
  successful: 0

**ALL**

Writes the input and output parameters for each invocation of the procedure or query to the report file. This is the default.

**ERROR**

Writes the input and output parameters for each invocation of the procedure or query to the report file only after a SQL error occurs.
STARTUPVALIDATIONDELAY[CSECS]

Valid For

Manager

Description

Use the STARTUPVALIDATIONDELAY or STARTUPVALIDATIONDELAYCSECS parameter to set a delay time after which Manager validates the status of a process that was started with the START EXTRACT or START REPLICAT command. If a process is not running after the specified delay time, an error message is displayed at the GGSCI prompt.

These parameters account for processes that fail before they can generate an error message or report, for example when there is not enough memory to launch the processes. Startup validation makes Oracle GoldenGate users aware of such failures.

Default

0 seconds (do not validate startup status)

Syntax

STARTUPVALIDATIONDELAY seconds | STARTUPVALIDATIONDELAYCSECS centiseconds

STARTUPVALIDATIONDELAY seconds
Specifies the delay in seconds.

STARTUPVALIDATIONDELAYCSECS centiseconds
Specifies the delay in centiseconds.

Example

In the following example, Manager waits ten centiseconds after a START command is issued and then checks the status of the process.

STARTUPVALIDATIONDELAYCSECS 10
STATOPTIONS

Valid For

Extract and Replicat

Description

Use the STATOPTIONS parameter to specify the information that is to be included in statistical displays generated by the STATS EXTRACT or STATS REPLICAT command. These options also can be enabled as needed as arguments to those commands.

Default

See individual options.

Syntax

STATOPTIONS
[
  [, REPORTDETAIL | NOREPORTDETAIL]
  [, REPORTFETCH | NOREPORTFETCH]
  [, RESETREPORTSTATS | NORESETREPORTSTATS]
  [, THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])]
]

REPORTDETAIL | NOREPORTDETAIL
Valid for Replicat. Controls the reporting of statistics for operations that were not applied to the target because they were discarded as the result of collision handling.

REPORTDETAIL
Returns statistics for the discarded operations. These operations are reported in the regular STATS REPLICAT statistics (inserts, updates, and deletes performed) and as discard statistics if STATS REPLICAT is issued with the DETAIL option. For example, if 10 records were INSERT operations and they were all ignored due to duplicate keys, the report would indicate that there were 10 inserts and also 10 discards due to collisions. REPORTDETAIL is the default.

NOREPORTDETAIL
Turns off the reporting of statistics for discarded operations.

REPORTFETCH | NOREPORTFETCH
Valid for Extract. Controls the reporting of statistics for the amount of row fetching performed by Extract, such as the fetches that are triggered by a FETCHCOLS clause or fetches that must be performed when not enough information is in the transaction record.

REPORTFETCH
Reports statistics for row fetching. The output is as follows:

- row fetch attempts: The number of times Extract attempted to fetch a column value from the database when it could not obtain the value from the transaction log.
- fetch failed: The number of row fetch attempts that failed.
- row fetch by key: (Valid for Oracle) The number of row fetch attempts that were made by using the primary key.
**NOREPORTFETCH**

Turns off the reporting of fetch statistics. NOREPORTFETCH is the default.

**RESETREPORTSTATS | NORESETREPORTSTATS**

Valid for Extract and Replicat. Controls whether or not statistics generated by the REPORT parameter are reset when a new report is created. RESETREPORTSTATS resets the statistics from one report to the other. NORESETREPORTSTATS continues the statistics from one report to another and is the default. See "REPORT" on page 3-240. Report rollover is controlled by the REPORTROLLOVER parameter. See "REPORTROLLOVER" on page 3-244.

**THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...])**

Enables the selected STATOPTIONS options for the specified threads of a coordinated Replicat.

- **threadID[, threadID][, ...]**
  Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

- **[, thread_range[, thread_range][, ...]**
  Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

**Examples**

**Example 1**

This example resets the statistics from one report to another for thread 0 of a coordinated Replicat.

```
STATOPTIONS RESETREPORTSTATS THREADS 0
```

**Example 2**

This example includes fetch details for thread 3 of a coordinated Replicat.

```
STATOPTIONS REPORTFETCH THREADS 3
```
SYSLOG

Valid For

GLOBALS, Manager

Description

Use the SYSLOG parameter to control the types of messages that Oracle GoldenGate sends to the system logs on a Windows or UNIX system, or to the SYSOPR message queue on an IBM i system. You can:

- include all Oracle GoldenGate messages
- suppress all Oracle GoldenGate messages
- filter to include information, warning, or error messages, or any combination of those types

You can use SYSLOG as a GLOBALS parameter or as a Manager parameter, or both. When present in the GLOBALS parameter file, it controls message filtering for all of the Oracle GoldenGate processes on the system. When present in the Manager parameter file, it controls message filtering only for the Manager process. If used in both the GLOBALS and Manager parameter files, the Manager setting overrides the GLOBALS setting for the Manager process. This enables you to use separate settings for Manager and all of the other Oracle GoldenGate processes.

Default

Write all Oracle GoldenGate messages to the system logs or SYSOPR message queue, depending on the platform.

Syntax

SYSLOG ([ALL | NONE] | [, INFO] [, WARN] [, ERROR])

ALL
Sends all INFO (information), WARN (warning), and ERROR (error) messages to the system log or SYSOPR message queue. This is the default and is the same as:

SYSLOG INFO, WARN, ERROR

Cannot be combined with other options. By default, INFO messages are not reported in the SQL/MX Event Management Service.

NONE
Prevents Oracle GoldenGate messages from being written to the system logs or SYSOPR message queue. Cannot be combined with other options.

INFO
Sends messages that are reported as INFO to the system logs or SYSOPR message queue. Can be combined with WARN and ERROR in any order.

By default, these messages are not reported in the SQL/MX Event Management Service.

WARN
Sends messages that are reported as WARN to the system logs or SYSOPR message queue. Can be combined with INFO and ERROR in any order.
**ERROR**
Sends messages that are reported as INFO to the system logs or SYSOPR message queue. Can be combined with INFO and WARN in any order.

**Example**

Either of the following statements sends warning and error messages to the system logs or SYSOPR message queue, but does not send informational messages.

SYSLOG WARN, ERROR

or:

SYSLOG ERROR, WARN
VALID FOR

**TABLE** is valid for Extract. **MAP** is valid for Replicat.

DESCRIPTION

The **TABLE** and **MAP** parameters control the selection, mapping, and manipulation of the objects that are to be affected by an Oracle GoldenGate process. These parameters work as follows:

- Use the **TABLE** parameter in an Extract parameter file to specify one or more objects that are to be captured from the data source by the Extract process. **TABLE** options specify processing work such as filtering and token definitions that must be performed before Extract writes the captured data to the Oracle GoldenGate trail.

- Use the **MAP** parameter in the Replicat parameter file to map the data from the source objects to the appropriate target objects. **MAP** options specify processing work such as filtering, conversion, and error handling that must be performed before the data is applied to the target objects. Each target object that you want to synchronize with a source object must be associated with that source object by means of a **MAP** parameter. Multiple source-target relationships can be specified by means of a wildcard.

**TABLE** and **MAP** are valid for initial load configurations and for online processes configured to support the replication of transactional changes.

You can process the following objects with **TABLE** and **MAP**:

- Indexes
- Triggers
- Materialized views
- Tables

To specify a sequence for capture by Extract, use the **SEQUENCE** parameter.

---

**Note:** Oracle GoldenGate supports the replication of the actual data values of Oracle materialized views. Oracle GoldenGate supports the replication of Oracle and Teradata DDL for indexes and triggers, but not the content of those objects.

---

You can use one or more **TABLE** or **MAP** statements in a parameter file, with or without wildcards, to specify all of the objects that you want to process.

You can exclude objects from a wildcarded **TABLE** or **MAP** statement with the **TABLEEXCLUDE** and **MAPEXCLUDE** parameters. Additional exclusion parameters are **CATALOGEXCLUDE**, **SCHEMAMEXCLUDE**, and **EXCLUDEWILDCARDOBJECTSONLY**.

For more information about using **TABLE** and **MAP**, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Default**

None
Syntax for TABLE

For tables, you can use all of the TABLE options. For non-table objects, use TABLE only to specify an object for capture.

```powershell
TABLE source_table[, TARGET target_table]
  [, COLMAP (column_mapping)]
  [, {COLS | COLSEXCEPT} (column_list)]
  [, {DEF | TARGETDEF} template]
  [, EVENTACTIONS action]
  [, EXITPARAM 'parameter']
  [, {FETCHCOLS | FETCHCOLSEXCEPT} (column_list)]
  [, {FETCHMODCOLS | FETCHMODCOLSEXCEPT} (column_list)]
  [, FETCHBEFOREFILTER]
  [, FILTER (filter_clause)]
  [, GETBEFORECOLS (column_specification)]
  [, KEYCOLS (columns)]
  [, SQLEXEC (SQL_specification)]
  [, SQLPREDICATE 'WHERE where_clause']
  [, TOKENS (token_definition)]
  [, TRIMSPACES | NOTRIMSPACES]
  [, TRIMVARSPACES | NOTRIMVARSPACES]
  [, WHERE (clause)]
```

Syntax for MAP

```powershell
MAP source_table, TARGET target_table
  [, COLMAP (column_mapping)]
  [, COMPARECOLS (column_specification)]
  [, COORDINATED]
  [, {DEF | TARGETDEF} template]
  [, EXCEPTIONSONLY]
  [, EXITPARAM 'parameter']
  [, EVENTACTIONS (action)]
  [, FILTER (filter_clause)]
  [, HANDLECOLLISIONS | NOHANDLECOLLISIONS]
  [, INSERTALLRECORDS]

TABLE and MAP Options

The following table summarizes the options that are available for the TABLE and MAP parameters. Note that not all options are valid for both parameters.
<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Valid For</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE source_table[, TARGET target_table]</td>
<td>Specifies the source object in a TABLE statement for Extract and an optional mapping to a target object. Use in the Extract parameter file.</td>
<td>TABLE</td>
</tr>
<tr>
<td>MAP source_table, TARGET target_table</td>
<td>Specifies the source-target object mapping for the Replicat process. Use in the Replicat parameter file.</td>
<td>MAP</td>
</tr>
<tr>
<td>COLMAP (column_mapping)</td>
<td>Maps records between different source and target columns.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>(COLS</td>
<td>COLSEXCEPT) (column_list)</td>
<td>Selects or excludes columns for processing.</td>
</tr>
<tr>
<td>COMPARECOLS (column_specification)</td>
<td>Specifies columns to use for conflict detection and resolution.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>COORDINATED</td>
<td>Forces a transaction to be processed as a barrier transaction.</td>
<td>MAP</td>
</tr>
<tr>
<td>(DEF</td>
<td>TARGETDEF) template</td>
<td>Specifies a source-definitions or target-definitions template.</td>
</tr>
<tr>
<td>EXCEPTIONONLY</td>
<td>Specifies that the MAP statement is an exceptions MAP statement.</td>
<td>MAP</td>
</tr>
<tr>
<td>EVENTACTIONS (action)</td>
<td>Triggers an action based on a record that satisfies a specified filter rule.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>EXITPARAM 'parameter'</td>
<td>Passes a parameter in the form of a literal string to a user exit.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>FETCHBEFOREFILTER</td>
<td>Directs the FETCHCOLS or FETCHCOLSEXCEPT action to be performed before a filter is executed.</td>
<td>TABLE</td>
</tr>
<tr>
<td>(FETCHCOLS</td>
<td>FETCHCOLSEXCEPT) (column_list)</td>
<td>Enables the fetching of column values from the source database when the values are not in the transaction record.</td>
</tr>
<tr>
<td>(FETCHMODCOLS</td>
<td>FETCHMODCOLSEXCEPT) (column_list)</td>
<td>Forces column values to be fetched from the database when the columns are present in the transaction log.</td>
</tr>
<tr>
<td>FILTER (filter_clause)</td>
<td>Selects records based on a numeric value. FILTER provides more flexibility than WHERE.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>GETBEFORECOLS (column_specification)</td>
<td>Forces before images of columns to be captured and written to the trail.</td>
<td>TABLE</td>
</tr>
<tr>
<td>HANDLECOLLISIONS</td>
<td>NOHANDLECOLLISIONS</td>
<td>Reconciles the results of changes made to the target table by an initial load process with those applied by a change-synchronization group.</td>
</tr>
<tr>
<td>INSERTALLRECORDS</td>
<td>Applies all row changes as inserts.</td>
<td>MAP</td>
</tr>
<tr>
<td>INSERTAPPEND</td>
<td>NOINSERTAPPEND</td>
<td>Controls whether or not Replicat uses an Oracle APPEND hint for INSERT statements.</td>
</tr>
<tr>
<td>KEYCOLS (columns)</td>
<td>Designates columns that uniquely identify rows.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>MAPEXCEPTION (exceptions_mapping)</td>
<td>Specifies that the MAP statement contains exceptions handling for wildcarded tables.</td>
<td>MAP</td>
</tr>
<tr>
<td>REPERERROR (error, response)</td>
<td>Controls how Replicat responds to errors when executing the MAP statement.</td>
<td>MAP</td>
</tr>
<tr>
<td>RESOLVECONFLICT (conflict_resolution_specification)</td>
<td>Specifies rules for conflict resolution.</td>
<td>MAP</td>
</tr>
<tr>
<td>SQLEXEC (SQL_specification)</td>
<td>Executes stored procedures and queries.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>SQLPREDICATE 'WHERE where_clause'</td>
<td>Enables a WHERE clause to select rows for an initial load.</td>
<td>TABLE</td>
</tr>
</tbody>
</table>
TABLE source_table[, TARGET target_table]

TABLE is valid in an Extract parameter file.

Use TABLE to specify a source object for which you want Extract to capture data. Specify the fully qualified two-part or three-part name of the object, such as schema.table or catalog.schema.table. You can use a wildcard to specify multiple objects with one TABLE statement. To specify object names and wildcards correctly, see Administering Oracle GoldenGate for Windows and UNIX.

Use the TARGET option only when Extract must refer to a target definitions file (specified with the TARGETDEFS parameter) to perform conversions or when the COLMAP option is used to map columns. Otherwise, it can be omitted from a TABLE parameter. Column mapping with COLMAP and conversion work usually are performed on the target system to minimize the impact of replication activities on the source system, but can be performed on the source system if required. For example, column mapping and conversion can be performed on the source system in a configuration where there are multiple sources and one target. In this scenario, it may be easier to manage one target definitions file rather than managing a definitions file for each source database, especially if there are frequent application changes that require new definitions files to be generated.

Using TARGET in a TABLE parameter identifies the metadata of the extracted data based on the target structure, rather than that of the source, to reflect the structure of the record that is reflected in the definitions file or the column map. Do not use three-part names if TARGET specifies tables in a target Oracle container database or SQL/MX database. Replicat can only connect to one container or catalog, so it is assumed that the container or catalog portion of the name is the same as the one that Replicat logs into (as specified with USERID, USERIDALIAS, or TARGETDB, depending on the database).

If no other TABLE syntax options are required to process the specified source data, you can use a simple TABLE statement, making sure to terminate it with a semicolon.

TABLE sales.customers;

The following shows the use of a wildcard to specify multiple tables:

TABLE sales.*;

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
<th>Valid For</th>
</tr>
</thead>
<tbody>
<tr>
<td>THREAD (thread_ID)</td>
<td>Valid for Replicat in coordinated mode. Specifies that the MAP statement will be processed by the specified Replicat thread.</td>
<td>MAP</td>
</tr>
<tr>
<td>THREADRANGE (thread_range, column_list)</td>
<td>Valid for Replicat in coordinated mode. Specifies that the MAP statement will be processed by the specified range of Replicat threads.</td>
<td></td>
</tr>
<tr>
<td>TOKENS (token_definition)</td>
<td>Defines user tokens.</td>
<td>TABLE</td>
</tr>
<tr>
<td>TRIMSPACES</td>
<td>NOTRIMSPACES</td>
<td>Controls whether trailing spaces are trimmed or not when mapping CHAR to VARCHAR columns.</td>
</tr>
<tr>
<td>TRIMVARSPACES</td>
<td>NOTRIMVARSPACES</td>
<td>Controls whether trailing spaces are trimmed or not when mapping VARCHAR to CHAR or VARCHAR columns.</td>
</tr>
<tr>
<td>WHERE (clause)</td>
<td>Selects records based on conditional operators.</td>
<td>TABLE and MAP</td>
</tr>
<tr>
<td>;</td>
<td>(Semicolon) Terminates the TABLE or MAP statement and is required.</td>
<td>TABLE and MAP</td>
</tr>
</tbody>
</table>
The preceding TABLE statements direct Extract to capture all supported column data for the specified objects and write it to the trail without performing any filtering, conversion, or other manipulation.

**MAP source_table, TARGET target_table**

MAP is valid in a Replicat parameter file.

Use MAP to specify a source object, and use TARGET to specify the target object to which Replicat applies the replicated source data. Together, the MAP and TARGET clause comprise a mapping.

- For MAP source_table, specify the source object. Specify the fully qualified two-part or three-part name of the object, such as schema.table or catalog.schema.table. You can use a wildcard to specify multiple source objects.

- For TARGET target_table, specify a two-part name, even if the target is a container database or SQL/MX database. Replicat can only connect to one container or catalog, so it is assumed that the container or catalog portion of the name is the same as the one that Replicat logs into (as specified with USERID, USERIDALIAS, or TARGETDB, depending on the database). You can use a wildcard to specify multiple target objects.

The following shows the use of a wildcard to specify multiple tables. Note that the TARGET clause does not include the tab prefix before the wildcard. That specification would be invalid, because the wildcard would be resolved as sales.tabtab1, sales.tabtab2, and so forth.

MAP sales.tab*, TARGET sales.*;

To specify object names and wildcards correctly in the MAP and TARGET clauses, see *Administering Oracle GoldenGate for Windows and UNIX*.

If no filtering, mapping, or other work is required for the objects, you can use simple MAP statements like the following, making sure to terminate each one with a semicolon.

MAP sales.customers, TARGET sales.customers;
MAP fin.*, TARGET fin.**;

**COLMAP (column_mapping)**

COLMAP is valid for TABLE and MAP.

Use COLMAP to:

- Map individual source columns to target columns when the source and target columns have different names.
- Specify default column mapping when the source and target names are identical.

COLMAP provides instructions for selecting, translating, and moving column data from a source column to a target column.

**Note:** To create global rules for column mapping across all tables in subsequent MAP statements, use the COLMATCH parameter.

**Getting More Information about Configuring Column Mapping**

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about using COLMAP. To use COLMAP, related configuration considerations must be taken into
account, such as whether source and target column structures are identical or different and whether global column mapping parameters may be sufficient.

Syntax

COLMAP (  
USEDEFAULTS,  
target_column = source_expression [BINARYINPUT]  
[, ...]  
)

USEDEFAULTS
Automatically maps source and target columns that have the same name if they were not specified in an explicit column mapping. The data types are translated automatically, as needed, based on the local data-definitions file. USEDEFAULTS eliminates the need for an explicit column mapping if those columns have the same name and the data does not require any filtering or conversion.

Specify USEDEFAULTS before explicit column mappings in the COLMAP clause. For additional information about default column mapping in COLMAP, see Administering Oracle GoldenGate for Windows and UNIX.

target_column = source_expression
Defines an explicit source-target column mapping.

  
target_column  
  Specifies the name of the target column. For supported characters in column names, see Administering Oracle GoldenGate for Windows and UNIX.

  source_expression  
  Can be any of the following:

  ■ The name of a source column, such as ORD_DATE
  ■ A numeric constant, such as 123
  ■ A string constant within single quotes, such as 'ABCD'
  ■ An expression using an Oracle GoldenGate column-conversion function, such as @STREXT(COL1, 1, 3). See "Column Conversion Functions" on page 5-1 for more information.

BINARYINPUT
Use BINARYINPUT when the target column is defined as a binary data type, such as RAW or BLOB, but the source input contains binary zeros in the middle of the data. Use BINARYINPUT when replicating a full Enscribe record defined as a single column into a target column. The source input is handled as binary input, and replacement of data values is suppressed.

Example 1

MAP ggs.tran, TARGET ggs.tran2, COLMAP (loc2 = loc, type2 = type);

Example 2

TABLE ggs.tran, COLMAP (SECTION = @STRCAT('§', SECTION ));

(COLS | COLSEXCEPT) (column_list)

COLS and COLSEXCEPT are valid for TABLE.

Use COLS and COLSEXCEPT to control the columns for which data is captured.
- **COLS** specifies columns that contain the data that you want to capture. When **COLS** is used, all columns that are not in the **COLS** list are ignored by Oracle GoldenGate.

- **COLSEXCEPT** specifies columns to exclude from being captured. When **COLSEXCEPT** is used, all columns that are not in the **COLSEXCEPT** list are captured by Oracle GoldenGate. For tables with numerous columns, **COLSEXCEPT** may be more efficient than listing each column with **COLS**.

  __Caution:__ Do not exclude key columns, and do not use **COLSEXCEPT** to exclude columns that contain data types that are not supported by Oracle GoldenGate. **COLSEXCEPT** does not exclude unsupported data types.

To use **COLS**, the following is required:

- The table must have one or more key columns, or a substitute key must be defined with the **KEYCOLS** option. See "**KEYCOLS** (columns)" on page 3-331.

- The key columns or the columns specified with **KEYCOLS** must be included in the column list that is specified with **COLS**. Otherwise, they will not be captured, and an error will be generated during processing.

Without a primary key, a unique key, or a **KEYCOLS** clause in the **TABLE** statement, Oracle GoldenGate uses all of the columns in the table, rendering **COLS** unnecessary.

  __Note:__ Do not use this option for tables that are processed in pass-through mode by a data-pump Extract group.

**Syntax**

```
{COLS | COLSEXCEPT} (column [, ...])
```

**column**

The name of a column. To specify multiple columns, create a comma-delimited list, for example:

```
COLS (name, city, state, phone)
```

  __Note:__ If the database only logs values for columns that were changed in an update operation, a column specified for capture with **COLS** might not be available. To make those columns available, use the **FETCHCOLS** option in the **TABLE** statement or enable supplemental logging for the column.

**Example**

The **COLS** clause in this example captures only columns 1 and 3, whereas the **COLSEXCEPT** clause captures all columns except columns 1 and 3.

```
TABLE hq.acct, COLS (col1, col3);
TABLE hq.sales, COLSEXCEPT (col1, col3);
```

**COMPARECOLS** (**column_specification**)

**COMPARECOLS** is valid for **MAP**.
Use `COMPARECOLS` to specify the columns that Replicat uses to detect and resolve update or delete conflicts when configured with the `RESOLVECONFLICT` option of `MAP` in a multi-master configuration. A conflict is a mismatch between the before image of a record in the trail and the correct data in the target table.

To use `COMPARECOLS`, the before image must be available in the trail record by means of the `GETBEFORECOLS` parameter in the Extract `TABLE` statement. The specified columns must exist in the target database and also be part of the Replicat configuration (satisfy the `TARGET` specification with or without a `COLMAP` clause).

Only scalar data types are supported by `COMPARECOLS` as comparison columns. A scalar data type can be used in a `WHERE` clause, has a single, atomic value and no internal components. Scalar data types supported by Oracle GoldenGate include the following, but not LOBs.

- Numeric data types
- Date data types
- Character data types

Some examples of non-scalar data types are spatial data, user-defined data types, large objects (LOB), XML, reference data types, and RAW. A row being considered for CDR can include non-scalar data so long as the conflict is not in the non-scalar data itself.

To specify conflict resolution routines, use the `RESOLVECONFLICT` option of `MAP`. `COMPARECOLS` and `RESOLVECONFLICT` can be in any order in the `MAP` statement.

### Getting More Information about Configuring the CDR Feature

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about configuring conflict detection and resolution.

### Syntax

```sql
COMPARECOLS(
{ON UPDATE | ON DELETE}
{ALL | KEY | KEYINCLUDING (col[,,...]) | ALLEXCLUDING (col[,,...]) }
[,...]
)

{ON UPDATE | ON DELETE}
```

Specifies whether the before image of the specified columns should be compared for updates or deletes. You can use `ON UPDATE` only, `ON DELETE` only, or both. If using both, specify them within the same `COMPARECOLS` clause. See the example for how to use both.

```sql
{ALL | KEY | KEYINCLUDING (col[,,...]) | ALLEXCLUDING (col[,,...])}
```

Specifies the columns for which a before image is captured.

- **ALL**
  Compares using all columns in the target table. An error is generated if any corresponding before images are not available in the trail. Using `ALL` imposes the highest processing load for Replicat, but allows conflict-detection comparisons to be performed using all columns for maximum accuracy.

- **KEY**
  Compares only the primary key columns. This is the fastest option, but does not permit the most accurate conflict detection, because keys can match but non-key columns could be different.
**KEYINCLUDING**

Compares the primary key columns and the specified column or columns. This is a reasonable compromise between speed and detection accuracy.

**ALLEXCLUDING**

Compares all columns except the specified columns. For tables with numerous columns, **ALLEXCLUDING** may be more efficient than **KEYINCLUDING**. Do not exclude key columns.

**Example 1**

In the following example, the key columns plus the name, address, and salary columns are compared for conflicts.

```
MAP src, TARGET tgt
COMPARECOLS {
  ON UPDATE KEYINCLUDING (name, address, salary),
  ON DELETE KEYINCLUDING (name, address, salary);
```

**Example 2**

In the following example, the comment column is ignored and all other columns are compared for conflicts.

```
MAP src, TARGET tgt
COMPARECOLS (ON UPDATE ALLEXCLUDING (comment))
```

**COORDINATED**

COORDINATED is valid for MAP. This option is valid when Replicat is in coordinated mode.

Use the **COORDINATED** option to force transactions made on objects in the same MAP statement to be processed as barrier transactions. It causes all of the threads across all MAP statements to synchronize to the same trail location. The synchronized position is the beginning of the transaction that contains a record that satisfies a MAP that contains the COORDINATED keyword. The transaction is then applied atomically by a single thread, which is either the thread with the lowest thread ID among the currently running threads or a dedicated thread with the ID of 0 if **USEDEDICATEDCOORDINATIONTHREAD** is specified in the parameter file.

**THREAD** and **THREADRANGE** clauses specified in conjunction with **COORDINATED** are ignored because the record will not be applied by the designated thread(s). The **COORDINATED** keyword results in temporarily suspending parallelism so that the target tables are in a consistent state before the force-coordinated transaction is applied. After this point, parallel execution commences again.

Replicat by default coordinates transactions in which the primary key is updated, transactions that perform DDL, and certain **EVENTACTIONS** actions. **COORDINATED** provides for explicit coordination.

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about coordinated Replicat.

**Syntax**

COORDINATED
Example

The following is an example of the use of the `COORDINATED` option. In this example, business rules require that the target tables be in a consistent state before Replicat executes transactions that include `SQLEXEC` operations on the objects specified in the `MAP` statement. Parallelism must be temporarily converted to serial SQL processing in this case.

Given the following `MAP` statement, if another thread inserts into `t2` a record with a value of 100 for `col_val` before the insert to `t1` is performed by thread 1, then the `SQLEXEC` will delete the row. If other threads are still processing the record that has the value of 100, the `SQLEXEC` fails. The results of this `MAP` statement are, therefore, not predictable.

```
MAP u1.t1, TARGET u2.t1 SQLEXEC (ID test2, QUERY ' delete from u2.t2 where col_val =100 ', NOPARAMS)), THREAD(1);
```

Conversely, when `COORDINATED` is used, all of the threads synchronize at a common point, including the one processing the `col_val=100` record, thereby removing the ambiguity of the results.

```
MAP u1.t1, TARGET u2.t1 SQLEXEC (ID test2, QUERY ' delete from u2.t2 where col_val =100 ', NOPARAMS)), THREAD(1), COORDINATED;
```

`{DEF | TARGETDEF} template`

`DEF` and `TARGETDEF` are valid for `TABLE` and `MAP`.

Use `DEF` and `TARGETDEF` to specify the name of a definitions template that was created by the `DEFGEN` utility.

- `DEF` specifies a source-definitions template.
- `TARGETDEF` specifies a target-definitions template.

A template is based on the definitions of a specific table. It enables new tables that have the same definitions as the original table to be added to the Oracle GoldenGate configuration without running `DEFGEN` for them, and without having to stop and start the Oracle GoldenGate process. The definitions in the template are used for definitions lookups.

Getting More Information about Creating Definitions Templates

For more information about templates and `DEFGEN`, see *Administering Oracle GoldenGate for Windows and UNIX*.

Syntax

```
{DEF | TARGETDEF} template
```

The name of one of the following definitions templates generated by the `DEFGEN` utility:

- Use `DEF` to specify a source-definitions template generated by the `DEF` option of the `TABLE` parameter in the `DEFGEN` parameter file.
- Use `TARGETDEF` to specify a target-definitions template generated by the `TARGETDEF` option of the `TABLE` parameter in the `DEFGEN` parameter file.

The definitions contained in the template must be identical to the definitions of the table or tables that are specified in the same `TABLE` or `MAP` statement.
Case-sensitivity of the template name is observed when the name is specified the same way that it is stored in the database. Make certain that the template name is specified the same way in both the DEF or TARGETDEF clause in this TABLE or MAP statement, and in the DEFGEN parameter file that created the template.

Example 1
This example shows a case-insensitive template name.
MAP acct.cust*, TARGET acct.cust*, DEF custdef;

Example 2
This example shows a case-sensitive template name when the database requires quotes to enforce case-sensitivity.
TABLE acct.cust*, DEF "CustDef";

Example 3
This example shows a case where both DEF and TARGETDEF are used.
MAP acct.cust*, TARGET acc.cust*, DEF custdef, TARGETDEF tcustdef;

EXCEPTIONSONLY
EXCEPTIONSONLY is valid for MAP.

Use EXCEPTIONSONLY in an exceptions MAP statement intended for error handling. The exceptions MAP statement must follow the MAP statement for which errors are anticipated. The exceptions MAP statement executes only if an error occurs for the last record processed in the preceding regular MAP statement.

To use EXCEPTIONSONLY, use a REPERROR statement with the EXCEPTION option either within the regular MAP statement or at the root of the parameter file. See "REPERROR" on page 3-226 for more information.

Note: If using the Oracle GoldenGate Conflict Detection and Resolution (CDR) feature, a REPERROR with EXCEPTION is not needed. CDR automatically sends all operations that cause errors to the exceptions MAP statement.

The exceptions MAP statement must specify the same source table as in the regular MAP statement, but the target table in the exceptions MAP statement must be an exceptions table. When using an exceptions MAP statement, do not use wildcarded object names in the regular MAP statement.

Note: See "MAPEXCEPTION (exceptions_mapping)" on page 3-332 to support wildcarded object names.

Getting More Information about Configuring Exceptions Handling
For more information about configuring exceptions handling with an exceptions MAP statement, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax
EXCEPTIONSONLY
**EVENTACTIONS** *(action)*

EVENTACTIONS is valid for TABLE and MAP. Some options apply only to one or the other parameter and are noted as such in the descriptions.

Use EVENTACTIONS to cause the process to take a defined action based on a record in the trail, known as the *event record*, that qualifies for a specific filter rule. You can use this system, known as the *event marker system* (or *event marker infrastructure*) to customize processing based on database events. For example, you can suspend a process to perform a transformation or report statistics. The event marker feature is supported for the replication of data changes, but not for initial loads.

To trigger actions that do not require data to be applied to target tables, you can use the Replicat TABLE parameter with filtering options that support EVENTACTIONS. See "**TABLE for Replicat**" on page 3-346 for more information.

---

**Caution:** EVENTACTIONS is not supported if the source database is Teradata and Extract is configured in maximum performance mode.

---

You may need to combine two or more actions to achieve your goals. When multiple actions are combined, the entire EVENTACTIONS statement is parsed first, and then the specified options execute in order of precedence. The following list shows the order of precedence. The actions listed before Process the record occur before the record is written to the trail or applied to the target (depending on the process). Actions listed after Process the record are executed after the record is processed.

TRACE
LOG
CHECKPOINT BEFORE
DISCARD
SHELL
ROLOVER
(Process the record)
IGNORE
REPORT
SUSPEND
ABORT
CHECKPOINT AFTER
FORCSTOP
STOP

To prevent the event record itself from being processed in the normal manner, use the IGNORE or DISCARD option. Because IGNORE and DISCARD are evaluated before the record itself, they prevent the record from being processed. Without those options, EVENTACTIONS for Extract writes the record to the trail, and EVENTACTIONS for Replicat applies that operation to the target database.

You should take into account the possibility that a transaction could contain two or more records that trigger an event action. In such a case, there could be multiple executions of certain EVENTACTIONS specifications. For example, encountering two qualifying records that trigger two successive Rollover actions will cause Extract to roll over the trail twice, leaving one of the two files empty of transaction data.

You should also take into account that when the GETUPDATEBEFORES parameter is in effect, two records are generated for UPDATE operations: a record that contains the before image and a record that contains the after image. An event action is triggered for each of those records when the operation qualifies as an event record. You can use
the BEFOREAFTERINDICATOR token of the GGHEADER column-conversion function as a filter in a FILTER clause to qualify the records so that the event action triggers only once, either on the before record or the after record, but not both.

The following example filters on the BEFORE indicator. The EVENTACTION issues the ECHO shell command to output the string 'Triggered on BEFORE' to the event log when a BEFORE record is encountered.

TABLE qasource.test, &
FILTER(@STRFIND('BEFORE', @GETENV('GGHEADER' , 'BEFOREAFTERINDICATOR')) > 0), &
EVENTACTIONS ( shell ('echo --== Triggered on BEFORE ==-- '), LOG);

The following shows the result of the event action:

013-03-06 17:59:31 INFO OGG-05301 Shell command output: '== Triggered on AFTER ==--'

The following example does the same thing, but for the AFTER indicator.

TABLE qasource.test, &
FILTER(@STRFIND('AFTER', @GETENV('GGHEADER' , 'BEFOREAFTERINDICATOR')) > 0), &
EVENTACTIONS ( shell ('echo --== Triggered on AFTER ==-- '), LOG);

In a Teradata configuration where Extract is configured in maximum protection mode, use EVENTACTIONS only in the VAM-sort Extract group. It is not supported by the primary Extract in this configuration because concurrent changes are not sorted in transaction order at this point in the processing stream. For more information, see Installing and Configuring Oracle GoldenGate for Teradata.

Getting More Information about Configuring the Event Marker System

See Administering Oracle GoldenGate for Windows and UNIX for more information about using EVENTACTIONS and the Event Marker System.

Syntax

EVENTACTIONS {
[STOP | SUSPEND | ABORT | FORCESTOP]
[IGNORE [RECORD | TRANSACTION [INCLUDEVENT]]]
[DISCARD]
[LOG [INFO | WARNING]]
[REPORT]
[ROLLOVER]
[SHELL 'command' |
  SHELL ('command', VAR variable = {column_name | expression}
  [, ...]) ]
[TRACE[2] file [TRANSACTION] [DDL(INCLUDE) | DDLONLY] [PURGE | APPEND]]
[CHECKPOINT [BEFORE | AFTER | BOTH]]
[, ...]
}

STOP
Valid in TABLE for Extract and in MAP for Replicat.

Brings the process to a graceful stop when the specified event record is encountered. The process waits for other operations within event transaction to be completed before stopping. If the transaction is a Replicat grouped or batched transaction, the current group of transactions are applied before the process stops gracefully. The process restarts at the next record after the event record, so long as that record also signified the end of a transaction.
The process logs a message if it cannot stop immediately because a transaction is still open. However, if the event record is encountered within a long-running open transaction, there is no warning message that alerts you to the uncommitted state of the transaction. Therefore, the process may remain running for a long time despite the STOP event.

**STOP**
can be combined with other **EVENTACTIONS** options except for **ABORT** and **FORCESTOP**.

**SUSPEND**
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Pauses the process so that it retains the active context of the current run and can still respond to **SEND** commands that are issued in GGSCI. When a process is suspended, the **INFO** command shows it as **RUNNING**, and the **RBA** field shows the last checkpoint position.

To resume processing, issue the **SEND** command with the **RESUME** option.

To use the **CHECKPOINT BEFORE** option in conjunction with **SUSPEND**, the event record must be the start of a transaction for the **SUSPEND** to take place. That way, if the process is killed while in the suspended state, the event record with the **SUSPEND** action is the first record to be reprocessed upon restart. If both **CHECKPOINT BEFORE** and **SUSPEND** are specified, but the event record is not the start of a transaction, the process abends before **SUSPEND** can take place.

To use the **CHECKPOINT AFTER** option in conjunction with **SUSPEND**, the **RESUME** command must be issued before the checkpoint can take place, and the event record must be a **COMMIT** record. If the process is killed while in a **SUSPEND** state, the process reprocesses the transaction from the last checkpointed position upon restart.

**SUSPEND** cannot be combined with **ABORT** but can be combined with all other options.

**ABORT**
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Forces the process to exit immediately when the specified event record is encountered, whether or not there are open transactions. The event record is not processed. A fatal error is written to the log, and the event record is written to the discard file if **DISCARD** is also specified. The process will undergo recovery on startup.

**ABORT** can be combined only with **CHECKPOINT BEFORE**, **DISCARD**, **SHELL**, and **REPORT**.

**FORCESTOP**
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Forces the process to stop gracefully when the specified event record is encountered, but only if the event record is the last operation in the transaction or the only record in the transaction. The record is written normally.

If the event record is encountered within a long-running open transaction, the process writes a warning message to the log and exits immediately, as in **ABORT**. In this case, recovery may be required on startup. If the **FORCESTOP** action is triggered in the middle of a long-running transaction, the process exits without a warning message.

**FORCESTOP** can be combined with other **EVENTACTIONS** options except for **ABORT**, **STOP**, **CHECKPOINT AFTER**, and **CHECKPOINT BOTH**. If used with **ROLLOVER**, the rollover only occurs if the process stops gracefully.

**IGNORE [RECORD | TRANSACTION [INCLUDEVENT]]**
Valid in **TABLE** for Extract and in **MAP** for Replicat.
Ignores some or all of the transaction, depending on the selected action.

- **RECORD** is the default. It forces the process to ignore only the specified event record, but not the rest of the transaction. No warning or message is written to the log, but the Oracle GoldenGate statistics are updated to show that the record was ignored.

- Use **TRANSACTION** to ignore the entire transaction that contains the record that triggered the event. If **TRANSACTION** is used, the event record must be the first one in the transaction. When ignoring a transaction, the event record is also ignored by default. **TRANSACTION** can be shortened to **TRANS**.

- Use **INCLUDEEVENT** with **TRANSACTION** to propagate the event record to the trail or to the target, but ignore the rest of the associated transaction.

**IGNORE** can be combined with all other **EVENTACTIONS** options except **ABORT** and **DISCARD**.

An **IGNORE** action is processed after all the qualification, filtering, mapping, and user-exit operations are processed. The record or transaction is ignored in the final output phase and prevents the record or transaction from being written to the output target (the trail in the case of Extract or the database in the case of Replicat). Therefore, in certain expressions, for example those that include **SQLEXEC** operations, the **SQLEXEC** will be executed before the **IGNORE** is processed. This means that, while the record is not written to the trail or target database, all of the effects of processing the record through qualification, filtering, mapping and user-exit will occur.

This action is not valid for DDL records. Because DDL operations are autonomous, ignoring a record is equivalent to ignoring the entire transaction.

**DISCARD**  
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Causes the process to:

- write the specified event record to the discard file.
- update the Oracle GoldenGate statistics to show that the record was discarded.

The process resumes processing with the next record in the trail.

**DISCARD** can be combined with all other **EVENTACTIONS** options except **IGNORE**.

**LOG [INFO | WARNING]**  
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Causes the process to log the event when the specified event record is encountered. The message is written to the report file, to the Oracle GoldenGate error log, and to the system event log.

Use the following options to specify the severity of the message:

- **INFO** specifies a low-severity informational message. This is the default.
- **WARNING** specifies a high-severity warning message.

**LOG** can be combined with all other **EVENTACTIONS** options except **ABORT**. If using **ABORT**, **LOG** is not needed because **ABORT** logs a fatal error before the process exits.

**REPORT**  
Valid in **TABLE** for Extract and in **MAP** for Replicat.

Causes the process to generate a report file when the specified event record is encountered. This is the same as using the **SEND** command with the **REPORT** option in **GGSCI**.
The **REPORT** message occurs after the event record is processed (unless **DISCARD**, **IGNORE**, or **ABORT** are used), so the report data will include the event record. **REPORT** can be combined with all other **EVENTACTIONS** options.

**ROLLOVER**
Valid in **TABLE** for Extract.
Causes Extract to roll over the trail to a new file when the specified event record is encountered. The **ROLLOVER** action occurs before Extract writes the event record to the trail file, which causes the record to be the first one in the new file unless **DISCARD**, **IGNORE** or **ABORT** are also used.

**ROLLOVER** can be combined with all other **EVENTACTIONS** options except **ABORT**.
**ROLLOVER** cannot be combined with **ABORT** because **ROLLOVER** does not cause the process to write a checkpoint, and **ROLLOVER** happens before **ABORT**.

Without a **ROLLOVER** checkpoint, **ABORT** causes Extract to go to its previous checkpoint upon restart, which would be in the previous trail file. In effect, this cancels the rollover.

**SHELL** '*command*
Valid in **TABLE** for Extract and in **MAP** for Replicat.
Causes the process to execute the specified shell command when the event record is encountered. **SHELL** '*command*' executes a basic shell command. The command string is taken at its literal value and sent to the system that way. The command is case-sensitive. Enclose the command string within single quote marks, for example:

```
EVENTACTIONS (SHELL 'echo hello world! > output.txt')
```

If the shell command is successful, the process writes an informational message to the report file and to the event log. Success is based upon the exit status of the command in accordance with the UNIX shell language. In that language, zero indicates success. If the system call is not successful, the process abends with a fatal error. In the UNIX shell language, non-zero equals failure. Note that the error message relates only to the execution of the **SHELL** command itself, and not the exit status of any subordinate commands. For example, **SHELL** can execute a script successfully, but commands in that script could fail.

**SHELL** can be combined with all other **EVENTACTIONS** options.

**SHELL** ('*command*', **VAR** variable = {column_name | expression} [, ...])
Valid in **TABLE** for Extract and in **MAP** for Replicat.
Causes the process to execute the specified shell command when the event record is encountered and supports parameter passing. The command and the parameters are case-sensitive.

When **SHELL** is used with arguments, the entire command and argument strings must be enclosed within parentheses, for example:

```
EVENTACTIONS (SHELL ('Current timestamp: $1  SQLEXEC result is $2 ',VAR $1 = @GETENV('JULIANTIMESTAMP'),VAR $2 = mytest.description));
```

The input is as follows:

```
command
```

Is the command, which is passed literally to the system.
VAR
Is a required keyword that starts the parameter input.

variable
Is the user-defined name of the placeholder variable where the run-time variable value will be substituted. Extra variables that are not used in the command are ignored. Note that any literal in the SHELL command that matches a VAR variable name is replaced by the substituted VAR value. This may have unintended consequences, so test your code before putting it into production.

column_name
Can be the before or after (current) image of a column value.

expression
can be the following, depending on whether column data or DDL is being handled.

- Valid expressions for column data:
  - The value from a TOKENS clause in a TABLE statement.
  - A return value from any Oracle GoldenGate column-conversion function.
  - A return value from a SQLEXEC query or procedure.
- Valid expressions for DDL:
  - Return value from @TOKEN function (Replicat only).
  - Return value from @GETENV function.
  - Return value from other functions that do not reference column data (for example, @DATENOW).
  - Return value from @DDL function.

TRACE[2] file [TRANSACTION] [DDL[INCLUDE] | DDLONLY] [PURGE | APPEND]
Valid in TABLE for Extract and in MAP for Replicat.

Causes process trace information to be written to a trace file when the specified event record is encountered. TRACE provides step-by-step processing information. TRACE2 identifies the code segments on which the process is spending the most time.

By default (without options), standard DML tracing without consideration of transaction boundaries is enabled until the process terminates.

- file specifies the name of the trace file and must appear immediately after the TRACE keyword. You can specify a unique trace file, or use the default trace file that is specified with the standalone TRACE or TRACE2 parameter.

  The same trace file can be used across different TABLE or MAP statements in which EVENTACTIONS TRACE is used. If multiple TABLE or MAP statements specify the same trace file name, but the TRACE options are not used consistently, preference is given to the options in the last resolved TABLE or MAP that contains this trace file.

- Use TRANSACTION to enable tracing only until the end of the current transaction, instead of when the process terminates. For Replicat, transaction boundaries are based on the source transaction, not the typical Replicat grouped or batched target transaction. TRANSACTION can be shortened to TRANS. This option is valid only for DML operations.

- DDL[INCLUDE] traces DDL and also DML transactional data processing. Either DDL or DDLINCLUDE is valid.
- **DDLONLY** traces DDL but does not trace DML transactional data.

  These options are valid only for Replicat. By default DDL tracing is disabled.

- Use **PURGE** to truncate the trace file before writing additional trace records, or use **APPEND** to write new trace records at the end of the existing records. **APPEND** is the default.

**TRACE** can be combined with all other **EVENTACTIONS** options except **ABORT**.

To disable tracing to the specified trace file, issue the GGSCI **SEND process** command with the **TRACE OFF file_name** option.

**CHECKPOINT [BEFORE | AFTER | BOTH]**

Valid in **TABLE** for Extract and in **MAP** for Replicat.

Causes the process to write a checkpoint when the specified event record is encountered. Checkpoint actions provide a context around the processing that is defined in **TABLE** or **MAP** statements. This context has a begin point and an end point, thus providing synchronization points for mapping the functions that are performed with **SQLEXEC** and user exits.

**BEFORE**

**BEFORE** for an Extract process writes a checkpoint before Extract writes the event record to the trail. **BEFORE** for a Replicat process writes a checkpoint before Replicat applies the SQL operation that is contained in the record to the target.

**BEFORE** requires the event record to be the first record in a transaction. If it is not the first record, the process will abend. Use **BEFORE** to ensure that all transactions prior to the one that begins with the event record are committed.

When using **EVENTACTIONS** for a DDL record, note that since each DDL record is autonomous, the DDL record is guaranteed to be the start of a transaction; therefore the **CHECKPOINT BEFORE** event action is implied for a DDL record.

**CHECKPOINT** **BEFORE** can be combined with all **EVENTACTIONS** options.

**AFTER**

**AFTER** for Extract writes a checkpoint after Extract writes the event record to the trail. **AFTER** for Replicat writes a checkpoint after Replicat applies the SQL operation that is contained in the record to the target.

**AFTER** flags the checkpoint request as an advisory, meaning that the process will only issue a checkpoint at the next practical opportunity. For example, in the case where the event record is one of a multi-record transaction, the checkpoint will take place at the next transaction boundary, in keeping with the Oracle GoldenGate data-integrity model.

When using **EVENTACTIONS** for a DDL record, note that since each DDL record is autonomous, the DDL record is guaranteed to be the end (boundary) of a transaction; therefore the **CHECKPOINT AFTER** event action is implied for a DDL record.

**CHECKPOINT** **AFTER** can be combined with all **EVENTACTIONS** options except **ABORT**.

**BOTH**

**BOTH** combines **BEFORE** and **AFTER**. The Extract or Replicat process writes a checkpoint before and after it processes the event record.

**CHECKPOINT** **BOTH** can be combined with all **EVENTACTIONS** options except **ABORT**.

**CHECKPOINT** can be shortened to **CP**.
Example 1
The following example shows how you can configure a process to ignore certain records. When Extract processes any trail record that has name = abc, it ignores the record.

```
TABLE fin.cust, &
WHERE [name = 'abc'], &
EVENTACTIONS (ignore);
```

Example 2
Based on the compatibility and precedence rules of EVENTACTIONS options, DISCARD takes higher precedence than ABORT, so in this example the event record gets written to the discard file before the process abends.

```
MAP fin.cust, TARGET fin.cust2, &
WHERE [name = 'abc'], &
EVENTACTIONS (DISCARD, ABORT);
```

Example 3
The following example executes a SHELL action. It gets the result of a SQLEXEC query and pairs it with the current timestamp.

```
TABLE src.tab &
SQLEXEC (id mytest, query 'select description from lookup &
where pop = :mycol2', params (mycol2 = col2) ), &
EVENTACTIONS (SHELL ('Current timestamp: $1  SQLEXEC result is $2 ', &
VAR $1 = @GETENV('JULIANTIMESTAMP'), VAR $2 = mytest.description));
```

The shell command that results from this example could be similar to the following:

```
'Current timestamp: 212156002704718000  SQLEXEC result is test passed'
```

Example 4
The following example shows how invalid results can occur if a placeholder name conflicts with literal text in the command string. In this example, a placeholder named $1 is associated with a column value, and the SHELL command echoes a literal string that includes $1.

```
MAP src.tab1, TARGET targ.tab1 &
EVENTACTIONS (SHELL ('echo Extra charge for $1 is $1', VAR $1 = COL1));
```

This is the unintended result, assuming the column value is gift wrap:

```
'Extra charge for gift wrap is gift wrap'
```

Changing the placeholder variable to $col results in the correct output:

```
MAP src.tab1, TARGET targ.tab1 &
EVENTACTIONS (SHELL ('echo Extra charge for $col is $1', VAR $col = COL1));
```

```
'Extra charge for gift wrap is $1'
```

The following shows similar potential for unintended results:

```
MAP src.tab1, TARGET targ.tab1 &
EVENTACTIONS (SHELL ('Timestamp: $1  Price is $13 > out.txt ', &
VAR $1 = @GETENV('JULIANTIMESTAMP')));
```

The redirected output file might contain a string like this (notice the second timestamp contains an appended value of 3):

```
'Timestamp: 212156002704718000 Price is 2121560027047180003'
```
The intended result is this:

'Timestamp: 212156002704718000 Price is $13'

**Example 5**

These examples show different ways to configure tracing.

```plaintext
MAP tab1, TARGET tab1 EVENTACTIONS (TRACE ./dirrpt/trace1.txt);
MAP tab2, TARGET tab2 EVENTACTIONS (TRACE ./dirrpt/trace2.txt TRANSACTION);
```

- In the first MAP statement, the trace1.txt trace file is generated just before the first tab1 event record is applied to the target. It contains all of the tracing information from that point forward until Replicat terminates or unless tracing is turned off with the GGSCI SEND REPLICAT command.

- Because the second MAP statement contains the TRANSACTION option, the trace2.txt file is generated just before the first tab2 event record is applied to the target, but the tracing stops automatically at the conclusion of the transaction that contains the tab2 event record.

**Example 6**

The following shows how EVENTACTIONS with SUSPEND can be used.

- **Case 1**: You are replicating DDL, and you want to ensure that there is enough space in the target database to create a new table. Use EVENTACTIONS with SUSPEND in the MAP statement that maps the CREATE TABLE DDL operation, and then execute a SQL statement in that MAP statement to query the amount of space remaining in a tablespace. If there is enough space, use SEND REPLICAT with RESUME to resume processing immediately; if not, leave Replicat suspended until a DBA can add the space, and then use SEND REPLICAT with RESUME to resume processing.

- **Case 2**: You want to fix unique key violations when they occur on any table. Because Replicat is processing thousands of tables, you do not want to stop the process each time there is a violation, because this would cause Replicat to spend time rebuilding the object cache again upon restart. By using EVENTACTIONS with SUSPEND, you can simply suspend processing until the problem is fixed.

- **Case 3**: At the end of the day, you suspend Replicat to run daily reports, and then resume processing immediately without stopping and restarting the process.

**EXITPARAM 'parameter'**

EXITPARAM is valid for TABLE and MAP.

Use EXITPARAM to pass a parameter to the EXIT_PARAMS function of a user exit routine whenever a record from the TABLE or MAP statement is encountered.

**Getting More Information about User Exits**

See *Administering Oracle GoldenGate for Windows and UNIX* for instructions on how to configure user exits.

See "User Exit Functions" for more information about the syntax for the user exits.

**Syntax**

EXITPARAM 'parameter string'
A parameter that is a literal string. Enclose the parameter within single quotes. You can specify up to 100 characters for the parameter string.

**FETCHBEFOREFILTER**

FETCHBEFOREFILTER is valid for TABLE.

Use FETCHBEFOREFILTER to fetch columns that are specified with FETCHCOLS or FETCHCOLSEXCEPT before a FILTER operation is executed. Fetching before the filter ensures that values required for the filter are available. Without FETCHBEFOREFILTER, fetches specified with FETCHCOLS or FETCHCOLSEXCEPT are not performed until after filters are executed. Specify FETCHBEFOREFILTER before FILTER in the parameter file.

Do not use this option for tables being processed in pass-through mode by a data-pump Extract group.

FETCHBEFOREFILTER is not supported for the SQL/MX database.

**Syntax**

FETCHBEFOREFILTER

**Example**

```plaintext
TABLE hr.salary, FETCHCOLS (sal_level),
FETCHBEFOREFILTER,
FILTER (sal_level >= 8)
```

**{FETCHCOLS | FETCHCOLSEXCEPT} (column_list)**

FETCHCOLS and FETCHCOLSEXCEPT are valid for TABLE. These options are only valid for the primary extract and cannot be used on data pump.

Use FETCHCOLS and FETCHCOLSEXCEPT to fetch column values from the database when the values are not present in the transaction log record. Use this option if the database only logs the values of columns that were changed in an update operation, but you need to ensure that other column values required for FILTER operations are available.

- FETCHCOLS fetches the specified columns.
- FETCHCOLSEXCEPT fetches all columns except the specified columns. For tables with numerous columns, FETCHCOLSEXCEPT may be more efficient than listing each column with FETCHCOLS.

FETCHCOLS and FETCHCOLSEXCEPT are valid for all databases that are supported by Oracle GoldenGate, except NonStop SQL/MX.

For an Oracle database, Oracle GoldenGate fetches the values from the undo tablespace through Oracle’s Flashback Query mechanism. The query provides a read-consistent image of the columns as of a specific time or SCN. For more information about how Oracle GoldenGate uses Flashback Query, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

Instead of using FETCHCOLS or FETCHCOLSEXCEPT, it may be more efficient to enable supplemental logging for the desired columns.

For Sybase, encrypted column data is not supported by these parameters because Oracle GoldenGate does not support Sybase encrypted data.
To control fetching and enable a response when a column specified for fetching cannot be located, use the `FETCHOPTIONS` parameter. To include fetch results in statistical displays generated by the `STATS EXTRACT` command, use the `STATOPTIONS` parameter.

If values for columns specified with `FETCHCOLS` or `FETCHCOLSEXCEPT` are present in the transaction log, no database fetch is performed. This reduces database overhead.

**Syntax**

```
{FETCHCOLS | FETCHCOLSEXCEPT} (column [, ...])
```

**column**

Can be one of the following:

- A column name or a comma-delimited list of column names, as in `(col1, col2)`.
- An asterisk wildcard, as in `(*)`.

**Example**

The `FETCHCOLS` clause in this example fetches *only* columns 1 and 3, whereas the `FETCHCOLSEXCEPT` clause fetches all columns *except* columns 1 and 3.

```
TABLE hq.acct, FETCHCOLS (col1, col3);
TABLE hq.sales, FETCHCOLSEXCEPT (col1, col3);
```

**{FETCHMODCOLS | FETCHMODCOLSEXCEPT} (column_list)**

`FETCHMODCOLS` and `FETCHMODCOLSEXCEPT` are valid for `TABLE`. These options are only valid for the primary extract and cannot be used on data pump.

Use `FETCHMODCOLS` and `FETCHMODCOLSEXCEPT` to force column values to be fetched from the database even if the columns are present in the transaction log. Depending on the database type, a log record can contain all of the columns of a table or only the columns that changed in the given transaction operation.

- `FETCHMODCOLS` fetches the specified columns.
- `FETCHMODCOLSEXCEPT` fetches all columns that are present in the transaction log, except the specified columns. For tables with numerous columns, `FETCHMODCOLSEXCEPT` might be more efficient than listing each column with `FETCHMODCOLS`.

`FETCHMODCOLS` and `FETCHMODCOLSEXCEPT` are valid for all databases that are supported by Oracle GoldenGate, except NonStop SQL/MX.

Observe the following usage guidelines:

- Do not use `FETCHMODCOLS` and `FETCHMODCOLSEXCEPT` for key columns.
- (Sybase) Do not use `FETCHMODCOLS` and `FETCHMODCOLSEXCEPT` for encrypted column data. Oracle GoldenGate does not support Sybase encrypted data.

**Syntax**

```
{FETCHMODCOLS | FETCHMODCOLSEXCEPT} (column [, ...])
```

`{column [, ...]}`

Can be one of the following:

- A column name or a comma-delimited list of column names, as in `(col1, col2)`.
- An asterisk wildcard, as in `(*)`. 

Example

The `FETCHMODCOLS` clause in this example fetches only columns 1 and 3, whereas the `FETCHMODCOLSEXCEPT` clause fetches all columns except columns 1 and 3.

\[
\begin{align*}
\text{TABLE } & hq.\text{acct}, \text{ FETCHMODCOLS } \{\text{col1, col3}\}; \\
\text{TABLE } & hq.\text{sales}, \text{ FETCHMODCOLSEXCEPT } \{\text{col1, col3}\};
\end{align*}
\]

**FILTER** *(filter_clause)*

FILTER is valid for TABLE and MAP.

Use FILTER to select or exclude records based on a numeric value. A filter expression can use conditional operators, Oracle GoldenGate column-conversion functions, or both.

**Note:** To filter based on a string, use one of the Oracle GoldenGate string functions. See "Column Conversion Functions" on page 5-1 for more information about these functions. You can also use the WHERE option. See "WHERE (clause)" on page 3-342.

Separate all FILTER components with commas. A FILTER clause can include the following:

- Numbers
- Columns that contain numbers
- Functions that return numbers
- Arithmetic operators:
  - + (plus)
  - - (minus)
  - * (multiply)
  - / (divide)
  - \ (remainder)
- Comparison operators:
  - > (greater than)
  - >= (greater than or equal)
  - < (less than)
  - <= (less than or equal)
  - = (equal)
  - <> (not equal)
- Parentheses (for grouping results in the expression)
- Conjunction operators: AND, OR

Enclose literals in single quotes. Specify case-sensitive column names as they are stored in the database, and enclose them in double quotes if the database requires quotes to enforce case-sensitivity (such as Oracle).
Oracle GoldenGate supports `FILTER` for columns that have a multi-byte character set.

### Getting More Information about Record Filtering

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about `FILTER` and other filtering options.

### Syntax

```
FILTER ( 
  [, ON INSERT | ON UPDATE | ON DELETE] 
  [, IGNORE INSERT | IGNORE UPDATE | IGNORE DELETE] 
  , filter_clause 
  [, RAISEERROR error_number] 
)
```

#### `filter_clause`

Selects records based on an expression, such as:

```
FILTER ((PRODUCT_PRICE*PRODUCT_AMOUNT) > 10000)
```

You can use the column-conversion functions of Oracle GoldenGate in a filter clause, as in:

```
FILTER (@COMPUTE (PRODUCT_PRICE*PRODUCT_AMOUNT)>10000)
```

Enclose literals in single quotes. Specify case-sensitive column names as they are stored in the database, and enclose them in double quotes if the database requires quotes to enforce case-sensitivity (such as Oracle).

Oracle GoldenGate does not support `FILTER` for columns that have a multi-byte character set or a character set that is incompatible with the character set of the local operating system.

The maximum size of the filter clause is 5,000 bytes.

#### `ON INSERT | ON UPDATE | ON DELETE`

Restricts record filtering to the specified operation(s). Separate operations with commas, for example:

```
FILTER (ON UPDATE, ON DELETE, 
@COMPUTE (PRODUCT_PRICE*PRODUCT_AMOUNT)>10000)
```

The preceding example executes the filter for `UPDATE` and `DELETE` operations, but not `INSERT` operations.

#### `IGNORE INSERT | IGNORE UPDATE | IGNORE DELETE`

Does not apply the filter for the specified operation(s). Separate operations with commas, for example:

```
FILTER (IGNORE INSERT, @COMPUTE (PRODUCT_PRICE*PRODUCT_AMOUNT)>10000)
```

The preceding example executes the filter on `UPDATE` and `DELETE` operations, but ignores `INSERT` operations.

#### `RAISEERROR` `error`

Raises a user-defined error number if the filter fails. Can be used as input to the `REPEERROR` parameter to invoke error handling. Make certain that the value for `error` is outside the range of error numbers that is used by the database or by Oracle GoldenGate. For example: `RAISEERROR 21000`. 
GETBEFORECOLS (column_specification)

GETBEFORECOLS is valid for TABLE.

Use GETBEFORECOLS to specify columns for which you want before image to be captured and written to the trail upon an update or delete operation. Use GETBEFORECOLS when using the Oracle GoldenGate Conflict Detection and Resolution (CDR) feature in a bi-directional or multi-master configuration. Also use it when using conversion functions or other processing features that require the before image of a record.

For updates, the before image of the specified columns is included in the trail whether or not any given column is modified. In addition to the columns specified in the GETBEFORECOLS clause, an Oracle database will also log the before image of other columns that are modified. For other supported databases, you can use the GETUPDATEBEFORES parameter to force the inclusion of the before values of other columns that are modified.

To use this parameter, supplemental logging must be enabled for any database that does not log before values by default.

GETBEFORECOLS overrides COMPRESSUPDATES and COMPRESSDELETES if used in the same parameter file.

This parameter is valid for all databases except DB2. For DB2 on all platforms that are supported by Oracle GoldenGate, use the GETUPDATEBEFORES parameter instead of GETBEFORECOLS.

Syntax

GETBEFORECOLS {
{ON UPDATE | ON DELETE}
{ALL | KEY | KEYINCLUDING (col[,....]) | KEYANDMOD | | ALLEXCLUDING (col[,....])} [...]
}

{ON UPDATE | ON DELETE}

Specifies whether the before image of the specified columns should be captured for updates or deletes. You can use ON UPDATE only, ON DELETE only, or both. If using both, specify them within the same GETBEFORECOLS clause. See the example for how to use both.

{ALL | KEY | KEYINCLUDING (col[,....]) | KEYANDMOD | ALLEXCLUDING (col[,....])}

Specifies the columns for which a before image is captured.

ALL

Captures a before image of all supported data type columns in the target table, including the primary key; all unsupported columns are skipped and logged in the Extract or Replicat parameter file as an information message. This imposes the highest processing load for Extract, but allows conflict-detection comparisons to be performed using all columns for maximum accuracy.
**KEY**
Capture before image only for the primary key. This is the fastest option, but does not permit the most accurate conflict detection, because keys can match but non-key columns could be different. **KEY** is the default.

**KEYINCLUDING**
Capture before image of the primary key and also the specified column or columns. This is a reasonable compromise between speed and detection accuracy.

**KEYANDMOD**
Use this option as an extension of the key option for both Extract and Replicat. For update DMLs on the source, Extract logs the key and modified columns. Replicat on the target will use the **KEY** and **MODIFIED** columns during conflict detection in a **WHERE** clause. With Oracle databases, the modified column is always used for conflict detection by default and this parameter makes it explicit.

**ALLEXCLUDING**
Capture before image of all columns except the specified columns. For tables with numerous columns, **ALLEXCLUDING** may be more efficient than **KEYINCLUDING**. Do **not** exclude key columns.

**Example**
In the following example, the before images for the key column(s) plus the name, address, and salary are always written to the trail file on update and delete operations.

```
TABLE src,
GETBEFORECOLS (  
ON UPDATE KEYINCLUDING (name, address, salary),  
ON DELETE KEYINCLUDING (name, address, salary));
```

**HANDLECOLLISIONS | NOHANDLECOLLISIONS**

**HANDLECOLLISIONS** and **NOHANDLECOLLISIONS** are valid for MAP.

Use **HANDLECOLLISIONS** and **NOHANDLECOLLISIONS** to control whether or not Oracle GoldenGate reconciles the results of an initial load with replicated transactional changes that are made to the same tables. When Oracle GoldenGate applies replicated changes after the load is finished, **HANDLECOLLISIONS** causes Replicat to overwrite duplicate records in the target tables and provides alternate handling of errors for missing records.

**HANDLECOLLISIONS** and **NOHANDLECOLLISIONS** can be used globally for all MAP statements in the parameter file or as an **ON/OFF** switch for groups of tables specified with MAP statements, and they can be used within a MAP statement. When used in a MAP statement, they override the global specifications.

See "**HANDLECOLLISIONS | NOHANDLECOLLISIONS**" on page 3-162 for syntax and usage.

**INSERTALLRECORDS**

**INSERTALLRECORDS** is valid for MAP.

Use the **INSERTALLRECORDS** parameter to convert all mapped operations to **INSERT** operations on the target. **INSERTALLRECORDS** can be used at the root level of the parameter file, within a **MAP** statement, and within a **MAPEXCEPTION** clause of a **MAP** statement.
See "INSERTALLRECORDS" on page 3-171 for syntax and usage.

**INSERTAPPEND | NOINSERTAPPEND**

**INSERTAPPEND** is valid for **MAP**.

Use the **INSERTAPPEND** and **NOINSERTAPPEND** parameters to control whether or not Replicat uses an APPEND hint when it applies INSERT operations to Oracle target tables. These parameters are valid only for Oracle databases.

See "INSERTAPPEND | NOINSERTAPPEND" on page 3-173 for syntax and usage.

**KEYCOLS (columns)**

**KEYCOLS** is valid for **TABLE** and **MAP**.

Use **KEYCOLS** to define one or more columns of the target table as unique. The primary use for **KEYCOLS** is to define a substitute primary key when a primary key or an appropriate unique index is not available for the table. You can also use **KEYCOLS** to specify additional columns to use in the row identifier that Replicat uses. Without the availability of a key or **KEYCOLS** clause, Replicat uses all columns of the table to build its **WHERE** clause, essentially performing a full table scan.

The columns of a key rendered by **KEYCOLS** must uniquely identify a row, and they must match the columns that are used as a key on the source table. The source table must contain at least as many key or index columns as the **KEYCOLS** key specified for the target table. Otherwise, in the event of an update to the source key or index columns, Replicat will not have the before images for the extra target **KEYCOL** columns.

When defining a substitute key with **KEYCOLS**, observe the following guidelines:

- If the source and target tables both lack keys or unique indexes, use a **KEYCOLS** clause in the **TABLE** parameter and in the **MAP** parameter, and specify matching sets of columns in each **KEYCOLS** clause.

- If either of the tables lacks a key or unique index, use **KEYCOLS** for that table. Specify columns that match the actual key or index columns of the other table. If a matching set cannot be defined with **KEYCOLS**, you must use **KEYCOLS** for the source table (**TABLE** parameter) and for the target table (**MAP** parameter). Specify matching sets of columns that contain unique values. **KEYCOLS** overrides a key or unique index.

- If the target table has a larger key than the source table does (or if it has more unique-index columns), use **KEYCOLS** in the **TABLE** statement to specify the source columns that match the extra target columns. You must also include the actual source key or index columns in this **KEYCOLS** clause. Using **KEYCOLS** in this way ensures that before images are available to Replicat in case the non-key columns are updated on the source.

When using **KEYCOLS**, make certain that the specified columns are configured for logging so that they are available to Replicat in the trail records. For an Oracle database, you can enable the logging by using the **COLS** option of the **ADD TRANDATA** command.

On the target tables, create a unique index on the **KEYCOLS**-defined key columns. An index improves the speed with which Oracle GoldenGate locates the target rows that it needs to process.

Do not use **KEYCOLS** for tables being processed in pass-through mode by a data-pump Extract group.
### Syntax

**KEYCOLS** (column [, ... ])

*column*

Defines a column to be used as a substitute primary key. If a primary or unique key exists, those columns must be included in the KEYCOLS specification. To specify multiple columns, create a comma-delimited list as in:

KEYCOLS (id, name)

The following column-types are not supported in KEYCOLS:

- Oracle column types not supported by KEYCOLS:
  
  Virtual columns, UDTs, function-based columns, and any columns that are explicitly excluded from the Oracle GoldenGate configuration.

- SQL Server, DB2 LUW, DB2 z/OS, MySQL, SQL/MX, Teradata, TimesTen column types not supported by KEYCOLS:
  
  Columns that contain a timestamp or non-materialized computed column, and any columns excluded from the Oracle GoldenGate configuration. For SQL Server Oracle GoldenGate enforces the total length of data in rows for target tables without a primary key to be below 8000 bytes.

- Sybase column types not supported by KEYCOLS:
  
  Computed columns, function-based columns, and any columns that are explicitly excluded from the GoldenGate configuration.

**Example**

TABLE hr.emp, KEYCOLS (id, first, last, birthdate);

**MAPEXCEPTION** *(exceptions_mapping)*

MAPEXCEPTION is valid for MAP.

Use MAPEXCEPTION as part of an exceptions MAP statement intended for error handling. MAPEXCEPTION maps failed operations that are flagged as exceptions by the REPERRO parameter to an exceptions table. Replicat writes the values of these operations along with other information to the exceptions table.

You can use MAPEXCEPTION within the same MAP statement that includes the source-target table mapping and other standard MAP options. The source and target table names can include wildcards.

When using MAPEXCEPTION, use a REPERRO statement with the EXCEPTION option either within the same MAP statement or at the root of the Replicat parameter file. See "EXCEPTIONSONLY" on page 3-315 and "REPERRO" on page 3-226.

**Getting More Information about Exceptions Handling**

For more information about configuring exceptions handling with an exceptions MAP statement, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Syntax**

MAPEXCEPTION (TARGET exceptions_table, INSERTALLRECORDS [, exception_MAP_options])
TARGET exceptions_table
The fully qualified name of the exceptions table. Standard Oracle GoldenGate rules for object names apply to the name of the exceptions table. See Administering Oracle GoldenGate for Windows and UNIX.

exception_MAP_options
Any valid options of the MAP parameter that you want to apply to the exceptions handling.

INSERTALLRECORDS
Applies all exceptions to the exceptions table as INSERT operations. This parameter is required when using MAPEXCEPTION.

Example
This is an example of how to use MAPEXCEPTION for exceptions mapping. The MAP and TARGET clauses contain wildcarded source and target table names. Exceptions that occur when processing any table with a name beginning with TRX will be captured to the fin.trxexceptions table using the specified mapping.

MAP src.trx*, TARGET trg.*, MAPEXCEPTION (TARGET fin.trxexceptions, INSERTALLRECORDS, COLMAP (USEDEFAULTS, ACCT_NO = ACCT_NO, OPTYPE = @GETENV ('LASTERR', 'OPTYPE'), DBERR = @GETENV ('LASTERR', 'DBERRNUM'), DBERRMSG = @GETENV ('LASTERR', 'DBERRMSG'))
);

REPERRO error, response
REPERRO is valid for MAP.
Use REPERRO to specify an error and a response that together control how Replicat responds to the error when executing the MAP statement. You can use REPERRO at the MAP level to override and supplement global error handling rules set with the REPERRO parameter at the root level of the parameter file. Multiple REPERRO statements can be applied to the same MAP statement to enable automatic, comprehensive management of errors and interruption-free replication processing.

For syntax and descriptions, see "REPERRO" on page 3-226.

RESOLVECONFLICT (conflict_resolution_specification)
RESOLVECONFLICT is valid for MAP.
Use RESOLVECONFLICT in a bi-directional or multi-master configuration to specify how Replicat handles conflicts on operations made to the tables in the MAP statement.

Multiple resolutions can be specified for the same conflict type and are executed in the order listed in RESOLVECONFLICT. Multiple resolutions are limited to INSERTROWEXISTS and UPDATEROWEXISTS conflicts only.

RESOLVECONFLICT can be used multiple times in a MAP statement to specify different resolutions for different conflict types.

The following are the data types and platforms that are supported by RESOLVECONFLICT.
RESOLVECONFLICT supports all databases that are supported by Oracle GoldenGate for Windows and UNIX.

To use RESOLVECONFLICT, the database must reside on a Windows, Linux, or UNIX system (including those running on NonStop OSS).

CDR supports data types that can be compared with simple SQL and without explicit conversion. See the individual parameter options for details.

Do not use RESOLVECONFLICT for columns that contain LOBs, abstract data types (ADT), or user-defined types (UDT).

Do not use RESOLVECONFLICT for BigNum data types in a SQL/MX database.

Getting More Information about Configuring Conflict Resolution
See Administering Oracle GoldenGate for Windows and UNIX for detailed instructions on configuring bi-directional replication and conflict resolution, including use cases and examples.

Syntax

RESOLVECONFLICT
{INSERTROWEXISTS | UPDATEROWEXISTS | UPDATEROWMISSING | DELETEROWEXISTS | DELETEROWMISSING)
( (DEFAULT | resolution_name),
 {USEMAX (resolution_column) | USEMAXEQ (resolution_column) | USEMIN (resolution_column) | USEMINEQ (resolution_column) | USEDELTA | DISCARD | OVERWRITE | IGNORE)
 [, COLS (column[,...])}

INSERTROWEXISTS | UPDATEROWEXISTS | UPDATEROWMISSING |
DELETEROWEXISTS | DELETEROWMISSING
The type of conflict that this resolution handles.

INSERTROWEXISTS
An inserted row violates a uniqueness constraint on the target.

UPDATEROWEXISTS
An updated row exists on the target, but one or more columns have a before image in the trail that is different from the current value in the database.

UPDATEROWMISSING
An updated row does not exist in the target.

DELETEROWEXISTS
A deleted row exists in the target, but one or more columns have a before image in the trail that is different from the current value in the database.

DELETEROWMISSING
A deleted row does not exist in the target.

DEFAULT | resolution_name

DEFAULT
The default column group. The resolution that is associated with the DEFAULT column group is used for all columns that are not in an explicitly named column group. You must define a DEFAULT column group.
**resolution_name**
A name for a specific column group that is linked to a specific resolution type. Supply a name that identifies the resolution type. Valid values are alphanumeric characters. Avoid spaces and special characters, but underscores are permitted, for example:

delta_res_method

Use either a named resolution or **DEFAULT**, but not both.

**USEMAX (resolution_column) | USEMAXEQ (resolution_column) | USEMIN (resolution_column) | USEMINEQ (resolution_column) | USEDELTA | DISCARD | OVERWRITE | IGNORE**
The conflict-handler logic that is used to resolve the conflict. Valid resolutions are:

**USEMAX**
If the value of **resolution_column** in the trail record is greater than the value of the column in the database, the appropriate action is performed:
- (INSERTROWEXISTS conflict) Apply the trail record, but change the insert to an update to avoid a uniqueness violation, and overwrite the existing values.
- (UPDATEROWEXISTS conflict) Apply the trail record as an update.

**USEMAXEQ**
If the value of **resolution_column** in the trail record is greater than or equal to the value of the column in the database, the appropriate action is performed:
- (INSERTROWEXISTS conflict) Apply the trail record, but change the insert to an update to avoid a uniqueness violation, and overwrite the existing values.
- (UPDATEROWEXISTS conflict) Apply the trail record as an update.

**USEMIN**
If the value of **resolution_column** in the trail record is less than the value of the column in the database, the appropriate action is performed:
- (INSERTROWEXISTS conflict) Apply the trail record, but change the insert to an update to avoid a uniqueness violation, and overwrite the existing values.
- (UPDATEROWEXISTS conflict) Apply the update from the trail record.

**USEMINEQ**
If the value of **resolution_column** in the trail record is less than or equal to the value of the column in the database, the appropriate action is performed:
- (INSERTROWEXISTS conflict) Apply the trail record, but change the insert to an update to avoid a uniqueness violation, and overwrite the existing values.
- (UPDATEROWEXISTS conflict) Apply the update from the trail record.

**resolution_column**
The name of a **NOT NULL** column that serves as the resolution column. This column must be part of the column group that is associated with this resolution. The value of the resolution column compared to the current value in the target database determines how a resolution should be applied. The after image of the resolution column is used for the comparison, if available; otherwise the before image value is used. Use a column that can be compared through simple SQL:
- NUMERIC
- DATE
To use a latest-timestamp resolution, use a timestamp column as the `resolution_column` and set the timestamp column to the current time when a row is inserted or updated. If possible, define the resolution column with the `SYSTIMESTAMP` data type, which supports fractional seconds. When comparisons are performed with sub-second granularity, there is little need for tie-breaking conflict handlers that resolve cases where the value of the resolution column is identical in both trail and target. If you ensure that the value of the timestamp column can only increase or only decrease (depending on the resolution), then `USEMAX` and `USEMIN` does not lead to data divergence.

**Note:** Do not use a primary key column as the resolution column in a `USEMAX` statement for the `UPDATEROWEXISTS` conflict. Otherwise, Replicat abends with an error similar to the following:

```
2013-04-04 10:18:38 ERROR OGG-01922 Missing RESOLUTION COLUMN NAME while mapping to target table "FIN"."ACCT".
```

**USEDELTA**

(UPDATEROWEXISTS conflict only) Add the difference between the before and after values in the trail record to the current value of the column in the target database. If any of the values is `NULL`, an error is raised. Base `USEDELTA` on columns that contain NUMERIC data types. `USEDELTA` is useful in a multi-node configuration when a row is getting simultaneously updated on multiple nodes. It propagates only the difference in the column values to the other nodes, so that all nodes become synchronized.

**DISCARD**

(Valid for all conflict types) Retain the current value in the target database, and write the data in the trail record to the discard file.

Use `DISCARD` with caution, because it can lead to data divergence.

**OVERWRITE**

(Valid for all conflict types except DELETEROWMISSING) Apply the trail record as follows:

- (INSERTROWEXISTS conflict) Apply the trail record but change the insert to an update to avoid a uniqueness violation, and overwrite the existing values.
- (UPDATEROWEXISTS conflict) Apply the update from the trail record.
- (UPDATEROWMISSING conflict) Apply the trail record but convert the missing `UPDATE` to an `INSERT` by using the modified columns from the after image and the unmodified columns from the before image. To convert an update to an insert, the before image of all columns of the row must be available in the trail. Use supplemental logging if the database does not log before images by default, and specify `ALL` for the Extract `GETBEFORECOLS` parameter.
- (DELETEROWEXISTS conflict) Apply the delete from the trail record, but use only the primary key columns in the `WHERE` clause.

Use `OVERWRITE` with caution, because it can lead to data divergence.
**IGNORE**
(Valid for all conflict types) Retain the current value in the target database, and ignore the trail record: Do not apply to the target table or a discard file.

**COLS** (column[, ...])
A non-default column group. This is a list of columns in the target database (after mapping) that are linked to, and operated upon by, a specific resolution type. If no column group is specified for a conflict, then all columns are affected by the resolution that is specified for the given conflict.

Alternatively, you can specify a DEFAULT column group, which includes all columns that are not listed in another column group. See the DEFAULT option.

You can specify multiple column groups, each with a different resolution. For example, you could use OVERWRITE for col2 and col3, and you could use USEDELTA for col4. No column in any group can be in any other group. Conflicts for columns in different column groups are resolved separately according to the specified resolution, and in the order listed.

Column groups work as follows:

- For INSERTROWEXISTS and UPDATEROWEXISTS conflicts, you can use different column groups to specify more than one of these conflict types and resolutions per table. Conflicts for columns in different column groups are resolved separately, according to the conflict resolution method specified for the column group.

- For UPDATEROWMISSING, DELETEROWEXISTS, and DELETEROWMISSING, you can use only one column group, and all columns of the table must be in this column group (considered the default column group).

**Examples**
The following examples are explained in detail in Administering Oracle GoldenGate for Windows and UNIX.

**Example 1**
This example demonstrates all conflict types with USEMAX, OVERWRITE, DISCARD.

```plaintext
MAP fin.src, TARGET fin.tgt,
COMPARECOLS (ON UPDATE ALL, ON DELETE ALL),
RESOLVECONFLICT (UPDATEROWEXISTS, (DEFAULT, USEMAX (last_mod_time))),
RESOLVECONFLICT (INSERTROWEXISTS, (DEFAULT, USEMAX (last_mod_time))),
RESOLVECONFLICT (DELETEROWEXISTS, (DEFAULT, OVERWRITE)),
RESOLVECONFLICT (UPDATEROWMISSING, (DEFAULT, OVERWRITE)),
RESOLVECONFLICT (DELETEROWMISSING, (DEFAULT, DISCARD)));
```

**Example 2**
This example demonstrates UPDATEROWEXISTS with USEDELTA and USEMAX.

```plaintext
MAP fin.src, TARGET fin.tgt,
COMPARECOLS
(ON UPDATE KEYINCLUDING (address, phone, salary, last_mod_time),
ON DELETE KEYINCLUDING (address, phone, salary, last_mod_time)),
RESOLVECONFLICT {
UPDATEROWEXISTS,
(delta_res_method, USEDELTA, COLS (salary)),
(DEFAULT, USEMAX (last_mod_time)));
```
Example 3

This example demonstrates \texttt{UPDATEROWEXISTS} with \texttt{USEDELTA}, \texttt{USEMAX}, and \texttt{IGNORE}.

\begin{verbatim}
MAP fin.src, TARGET fin.tgt,
    COMPARECOLS
    (ON UPDATE ALLEXCLUDING \{comment\}),
    RESOLVECONFLICT (UPDATEROWEXISTS,
        (delta_res_method, USEDELTA, COLS \{salary, balance\}),
        (max_res_method, USEMAX \{last_mod_time\}, COLS \{address, last_mod_time\}),
        (DEFAULT, IGNORE));
\end{verbatim}

\textbf{SQLEXEC (SQL\_specification)}

SQLEXEC is valid for \texttt{TABLE} and \texttt{MAP}.

Use SQLEXEC to execute a SQL stored procedure or query from within a MAP statement during Oracle GoldenGate processing. SQLEXEC enables Oracle GoldenGate to communicate directly with the database to perform any work that is supported by the database. This work can be part of the synchronization process, such as retrieving values for column conversion, or it can be independent of extracting or replicating data, such as executing a stored procedure that executes an action within the database.

See "SQLEXEC" on page 3-289 for syntax and usage.

\textbf{SQLPREDICATE 'WHERE where\_clause'}

SQLPREDICATE is valid for \texttt{TABLE}.

Use SQLPREDICATE to include a conventional SQL \texttt{WHERE clause} in the \texttt{SELECT} statement that Extract uses when selecting data from a table in preparation for an initial load. SQLPREDICATE forces the records returned by the selection to be ordered by the key values.

SQLPREDICATE is a faster selection method for initial loads than the \texttt{WHERE} or \texttt{FILTER} options. It affects the SQL statement directly and does not require Extract to fetch all records before filtering them.

For Oracle tables, SQLPREDICATE reduces the amount of data that is stored in the undo segment, which can reduce the incidence of snapshot-too-old errors. This is useful when loading very large tables.

By using a SQLPREDICATE clause, you can partition the rows of a large table among two or more parallel Extract processes. This configuration enables you to take advantage of parallel delivery load processing as well.

SQLPREDICATE also enables you to select data based on a timestamp or other criteria to filter the rows that are extracted and loaded to the target table. SQLPREDICATE can be used for \texttt{ORDER BY} clauses or any other type of selection clause.

Make certain that the \texttt{WHERE} clause contains columns that are part of a key or index. Otherwise, Extract performs a full table scan, which reduces the efficiency of the \texttt{SELECT} statement.

SQLPREDICATE is valid for Oracle, DB2 LUW, DB2 on z/OS, SQL Server, and Teradata databases. Do not use SQLPREDICATE for an Extract group that is configured to synchronize transactional changes. It is only appropriate for an initial load Extract, because it requires a \texttt{SELECT} statement that selects records directly from tables.

\textbf{Syntax}

\begin{verbatim}
TABLE source_table, SQLPREDICATE 'WHERE where\_clause';
\end{verbatim}
WHERE
This is a required keyword.

where_clause
A valid SQL WHERE clause that selects records from the source tables.

Example
TABLE hr.emp, SQLPREDICATE 'WHERE state = 'CO' and city = 'DENVER''

THREAD (thread_ID)
THREAD is valid for MAP. This option is valid when Replicat is in coordinated mode.
Use THREAD to specify that all of the object or objects in the same MAP statement are to be processed by the specified Replicat thread. The specified thread handles filtering, manipulation, delivery to the target, error handling, and other work that is configured for those objects. Wildcards can be used in the TARGET clause when THREAD is used.
All tables that have referential dependencies among one another must be mapped in the same thread. For example, if tables scott.cust and scott.ord have a foreign-key relationship, the following is a possible mapping:
MAP scott.cust, TARGET scott.cust, THREAD (5);
MAP scott.ord, TARGET scott.ord, THREAD (5);

The thread with the lowest thread ID always processes barrier transactions if the THREAD or THREADRANGE option is omitted. Additionally, and work that is not explicitly assigned to a thread is processed through this thread. For example, if there are threads with IDs ranging from 1 to 10, barrier and non-assigned transactions are performed by thread 1.
To process a MAP statement among multiple threads, see THREADRANGE (thread_range, column_list). THREAD and THREADRANGE are mutually exclusive options. Do not use them together in the same MAP statement.
For more information about Replicat modes, see "Deciding Which Apply Method to Use" in Installing and Configuring Oracle GoldenGate for Oracle Database and "BATCHSQL" on page 3-26.

Syntax
THREAD (thread_ID)

thread_ID
A numerical identifier for the thread that will process this MAP statement. Valid values are 1 through the value that was specified with the MAXTHREADS option of the ADD REPLICAT command that created this group. You can use the INFO REPLICAT command to verify the maximum number of threads allowed for a Replicat group. When specifying thread IDs, the following must be true:

- The total number of threads specified across all MAP statements of a Replicat group cannot exceed the value of MAXTHREADS.
- No single thread_ID value in the Replicat group can be higher than the value of MAXTHREADS. For example, if MAXTHREADS is 25, there cannot be a thread_ID of 26 or higher.

If MAXTHREADS was not used, the default maximum number of threads is 25.
**Examples**
The following examples show some ways to use the THREAD option.

**Example 1**
In this example, thread 1 processes table cust.

```
MAP scott.cust, TARGET scott.cust, THREAD (1);
```

**Example 2**
In this example, thread 1 processes all of the tables in the scott schema.

```
MAP scott.*, TARGET scott.*, THREAD (1);
```

**Example 3**
In this example, the orders table is partitioned among two MAP statements through the use of FILTER (filter_clause) and the @RANGE function. For more information about @RANGE, see "RANGE" on page 5-43.

```
MAP scott.orders, TARGET scott.orders, FILTER (@RANGE (1, 2, OID)), THREAD (1);
MAP scott.orders, TARGET scott.orders, FILTER (@RANGE (2, 2, OID)), THREAD (2);
```

**THREADRANGE (thread_range, column_list)**

THREADRANGE is valid for MAP. This option is valid when Replicat is in coordinated mode.

Use THREADRANGE to specify that the workload of the target table is to be partitioned evenly among a range of Replicat threads, based on the value of a specified column or columns. For example, if the partitioning is based on the value of a column named ID, and the THREADRANGE value is 1-3, then thread 1 processes rows with ID values from 1 through 10, thread 2 processes rows with ID values from 11 through 20, and thread 3 processes rows with ID values from 21 through 30. The partitioning may not be as absolutely even as shown in the preceding example, depending on the initial calculation of the workload, but it is coordinated so that same row is always processed by the same thread. Each specified thread handles filtering, manipulation, error handling, delivery to the target, and other work for its range of rows.

Partitioning a table across a range of threads may improve apply performance for very large tables or tables that frequently incur long-running transactions or heavy volume, but can be used in other cases, as well. You can process more than one table through the same range of threads.

A wildcarded TARGET clause can be used when THREADRANGE is used if the optional column list is omitted. When using a column list, use separate explicit MAP statements for each table that is using the same thread range.

To process a MAP statement with one specific thread, see THREAD (thread_ID). THREAD and THREADRANGE are mutually exclusive options. Do not use them together in the same MAP statement.

Do not specify tables that have referential dependencies among one another in a thread range. Use the THREAD option and process all of those tables with the same thread.

Do not use THREADRANGE to partition sequences. If coordination is required, for example when a sequence is part of a SQLEXEC operation, partition the sequence work to one thread with the THREAD option.
The thread with the lowest thread ID always processes barrier transactions if the THREAD or THREADRANGE option is omitted. Additionally, and work that is not explicitly assigned to a thread is processed through this thread. For example, if there are threads with IDs ranging from 1 to 10, barrier and non-assigned transactions are performed by thread 1.

For more information about Replicat modes, see "Deciding Which Apply Method to Use" in Installing and Configuring Oracle GoldenGate for Oracle Database and "BATCHSQL" on page 3-26.

Syntax
THREADRANGE (lowID-highID[, column[, column][,...]])

lowID
The lowest thread identifier of this range. Valid values are 1 through 500.

highID
The highest thread identifier of this range, which must be a higher number than lowID. Valid values are lowID+1 through 500. The number of threads in the range cannot exceed the value that was specified with the MAXTHREADS option of the ADD REPLICAT command. If MAXTHREADS was not used, the default maximum number of threads is 25.

[column[, column][,...]]
Optional. Specifies one or more unique columns on which to base the row partitioning. To specify multiple columns, use a comma-delimited list, such as col1, col2, col3. When this option is omitted, the partitioning among the threads is based by default on the following columns, in the order of preference shown:

- Primary key
- KEYCOLS clause in the same MAP statement
- All of the columns of the table that are supported by Oracle GoldenGate for use as a key.

Example
The following example divides the orders and order_lines tables between the same two threads, based on the value of the OID column.

MAP scott.orders, TARGET scott.orders, THREADRANGE (1-2, OID);
MAP scott.order_lines, TARGET scott.order_lines, THREADRANGE (1-2, OID);

TOKENS (token_definition)
TOKENS is valid for TABLE.

Use TOKENS to define a user token and associate it with data. Tokens enable you to extract and store data within the user token area of a trail record header. Token data can be retrieved and used in many ways to customize the way that Oracle GoldenGate delivers data. For example, you can use token data in column maps, stored procedures called by SQLEXEC, or macros.

To use the defined token data in target tables, use the @TOKEN column-conversion function in the COLMAP clause of a Replicat MAP statement. The @TOKEN function maps the name of a token to a target column.

Do not use this option for tables being processed in pass-through mode by a data-pump Extract group.
The character set of token data is not converted. The token must be in the character set of the source database for Extract and in the character set of the target database for Replicat.

Do not use this option for source tables that are encoded as EBCDIC on a z/OS system if the target tables are not EBCDIC.

For more information about using tokens, see Administering Oracle GoldenGate for Windows and UNIX.

**Syntax**

```
TOKENS (token_name = token_data [, ...])
```

- **token_name**
  A name of your choice for the token. It can be any number of valid characters and is not case-sensitive. Multi-byte names are not supported.

- **token_data**
  Any valid character string of up to 2000 bytes. The data can be either a literal that is enclosed within single quotes (or double quotes if `NOUSEANSISQLQUOTES` is in use) or the result of an Oracle GoldenGate column-conversion function. See "USEANSISQLQUOTES | NOUSEANSISQLQUOTES" on page 3-400 for more information.

**Example**

The following creates tokens named `TK-OSUSER`, `TK-GROUP`, and `TK-HOST` and maps them to token data obtained with the `@GETENV` function.

```sql
TABLE ora.oratest, TOKENS {
  TK-OSUSER = @GETENV ('GGENVIRONMENT', 'OSUSERNAME'),
  TK-GROUP = @GETENV ('GGENVIRONMENT', 'GROUPNAME'),
  TK-HOST =  @GETENV ('GGENVIRONMENT', 'HOSTNAME'));
```

---

**TRIMSPACES | NOTRIMSPACES**

TRIMSPACES and NOTRIMSPACES are valid for TABLE and MAP.

Use TRIMSPACES and NOTRIMSPACES at the root level of a parameter file or within a TABLE or MAP statement to control whether or not trailing spaces in a source CHAR column are truncated when applied to a target CHAR or VARCHAR column. The default is TRIMSPACES.

See "TRIMSPACES | NOTRIMSPACES" on page 3-393 for syntax and usage.

**TRIMVARSPACES | NOTRIMVARSPACES**

TRIMVARSPACES and NOTRIMVARSPACES are valid for TABLE and MAP.

Use TRIMVARSPACES and NOTRIMVARSPACES at the root level of a parameter file or within a TABLE or MAP statement to control whether or not trailing spaces in a source VARCHAR column are truncated when applied to a target CHAR or VARCHAR column. The default is NOTRIMVARSPACES.

See "TRIMVARSPACES | NOTRIMVARSPACES" on page 3-394 for syntax and usage.

**WHERE (clause)**

WHERE is valid for TABLE and MAP.
Use `WHERE` to select records based on a conditional statement. `WHERE` does not support the following:

- Columns that have a multi-byte character set or a character set that is incompatible with the character set of the local operating system.
- The evaluation of the before image of a primary key column in the conditional statement as part of a primary key update operation.

Enclose literals in single quotes. Specify case-sensitive column names as they are stored in the database, and enclose them in double quotes if the database requires quotes to enforce case-sensitivity (such as Oracle).

**Getting More Information about Record Filtering**

See *Administering Oracle GoldenGate for Windows and UNIX* for more information about `WHERE` and other filtering options.

**Syntax**

```
WHERE {clause}
```

**clause**

Selects records based on a condition, such as:

```
WHERE {branch = 'NY'}
```

Table 3–34 shows permissible `WHERE` operators.

**Table 3–34  Permissible WHERE Operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column names</td>
<td><code>PRODUCT_AMT</code> &lt;br&gt;``Product_Amt''</td>
</tr>
<tr>
<td>Numeric values</td>
<td>-123, 5500.123</td>
</tr>
<tr>
<td>Literal strings enclosed in single quotes</td>
<td><code>'AUTO', 'Ca'</code></td>
</tr>
<tr>
<td>Column tests</td>
<td><code>@NULL, @PRESENT, @ABSENT</code> (column is null, present or absent in the record). These tests are built into Oracle GoldenGate.</td>
</tr>
<tr>
<td>Comparison operators</td>
<td><code>=, &lt;&gt;, &gt;, &lt;, &gt;=, &lt;=</code></td>
</tr>
<tr>
<td>Conjunctive operators</td>
<td>AND, OR</td>
</tr>
<tr>
<td>Grouping parentheses</td>
<td>Use open and close parentheses for logical grouping of multiple elements.</td>
</tr>
</tbody>
</table>

**Example**

The following `WHERE` example returns all records when the `AMOUNT` column is over 10,000 and does not cause a record to be discarded when `AMOUNT` is absent.

```
WHERE (amount = @PRESENT AND amount > 10000)
```
TABLE for DEFGEN

Valid For

DEFGEN

Description

Use the TABLE parameter in a DEFGEN parameter file to identify a source table or tables for which you want to run the utility.

You can output definitions for objects that are in different containers in an Oracle container database or from different SQL/MX catalogs to the same definitions file. All table attributes must be identical, such as case sensitivity, character set, and the use of the full three-part name. For example, you cannot use two-part names (stripped of their container or catalog by the NOCATALOG parameter) and three-part names in the same definitions file.

Default

None

Syntax

TABLE [catalog.]owner.table[, DEF template];

[catalog.]owner.table
The container (Oracle container database) or catalog (SQL/MX) if applicable, and the owner and name of the table. This parameter accepts wildcards. Oracle GoldenGate automatically increases the internal storage to track up to 100,000 wildcard entries.

Oracle GoldenGate preserves the case of the table name. Some databases require a name to be within double quotes to enforce case-sensitivity. Other case-sensitive databases do not require double quotes to enforce case-sensitivity, but the names must be specified the way they are stored in the database. See Administering Oracle GoldenGate for Windows and UNIX for how to specify object names.

DEF template
Creates a definitions template based on the definitions of the specified table. A template enables new tables that have the same definitions as the specified table to be added during an Oracle GoldenGate process run, without the need to run DEFGEN for them first, and without the need to stop and start the Oracle GoldenGate process to update its definitions cache. To use a template that is generated by DEFGEN, specify it with the DEF or TARGETDEF option of the TABLE or MAP statement. To retain case-sensitivity, specify the template name the way you would specify any case-sensitive object in the database. This option is not supported for initial loads.

;
Terminates the TABLE statement.

Examples

Example 1
TABLE fin.account;
Example 2
TABLE fin.acc*;

Example 3
TABLE fin.'acct1', DEF 'acctdefs';
TABLE for Replicat

Valid For

Replicat

Description

Use the TABLE parameter in a Replicat parameter file to specify filtering rules that qualify a data record from the trail to be eligible for an event action that is specified with EVENTACTIONS.

Caution: EVENTACTIONS is not supported if the source database is Teradata and Extract is configured in maximum performance mode.

This form of TABLE statement is similar to that of the Replicat MAP statement, except that there is no mapping of the source table in the data record to a target table by means of a TARGET clause. TABLE for Replicat is solely a means of triggering a non-data action to be taken by Replicat when it encounters an event record. If Replicat is in coordinated mode, all actions are processed through the thread with the lowest thread ID.

Because a target table is not supplied, the following apply:

- No options are available to enable Replicat to map table names or columns to a target table, nor are there options to enable Replicat to manipulate data.
- The ASSUMETARGETDEFS parameter cannot be used in the same parameter file as a Replicat TABLE statement, because ASSUMETARGETDEFS requires the names of target tables so that Replicat can query for table definitions. You must create a source-definitions file to provide the definitions of the source tables to Replicat. Transfer this file to the target system and use the SOURCEDEFS parameter in the Replicat parameter file to specify the path name of the file. See Administering Oracle GoldenGate for Windows and UNIX for more information about creating source-definitions files.
- The event record itself is not applied to the target database by Replicat. You must specify either IGNORE or DISCARD as one of the EVENTACTIONS options.

See Administering Oracle GoldenGate for Windows and UNIX for information about how to specify object names in TABLE statements.

See Administering Oracle GoldenGate for Windows and UNIX for more information about how to use EVENTACTIONS and the Event Marker System.

Syntax

See "TABLE | MAP" on page 3-305 for descriptions of the following syntax options.

```
TABLE table_spec,
[, SQLEXEC (SQL_specification), BEFOREFILTER]
[, FILTER (filter_clause)]
[, WHERE (where_clause)]
[, EVENTACTIONS ({IGNORE | DISCARD} [action])]
;
```
Example

The following example enables Replicat tracing for an order transaction that contains an insert operation for a specific order number (order_no = 1). The trace information is written to the order_1.trc trace file. The MAP parameter specifies the mapping of the source table to the target table.

```
MAP sales.order, TARGET rpt.order;
TABLE sales.order,
FILTER (@GETENV ('GGHEADER', 'OPTYPE') = 'INSERT' AND @STREQ (order_no, 1), &
EVENTACTIONS (TRACE order_1.trc TRANSACTION);
```
TABLEEXCLUDE

Valid For

Extract

Description

Use the TABLEEXCLUDE parameter with the TABLE and SEQUENCE parameters to explicitly exclude tables and sequences from a wildcard specification. The positioning of TABLEEXCLUDE in relation to parameters that specify files or trails determines its effect. Parameters that specify trails or files are: EXTFILE, RMTFILE, EXTTRAIL, RMTTRAIL. The parameter works as follows:

- When a TABLEEXCLUDE specification is placed before any TABLE or SEQUENCE parameters, and also before the parameters that specify trails or files, it applies globally to all trails or files, and to all TABLE and SEQUENCE parameters.

- When a TABLEEXCLUDE specification is placed after a parameter that specifies a trail or file, it is effective only for that trail or file and only for the TABLE or SEQUENCE parameters that are associated with it. Multiple trail or file specifications can be made in a parameter file, each followed by a set of TABLE, SEQUENCE, and TABLEEXCLUDE specifications.

TABLEEXCLUDE is evaluated before evaluating the associated TABLE or SEQUENCE parameter. Thus, the order in which they appear does not make a difference.

When using wildcards, be careful not to place them such that all objects are excluded, leaving nothing to capture. For example, the following captures nothing:

```
TABLE cat1.schema*.tab*;
TABLEEXCLUDE cat1.*.*
```

The default for resolving wildcards is WILDCARDRESOLVE DYNAMIC. Therefore, if a table that is excluded with TABLEEXCLUDE is renamed to a name that satisfies a wildcard, the data will be captured. The DYNAMIC setting enables new table names that satisfy a wildcard to be resolved as soon as they are encountered and included in the Oracle GoldenGate configuration immediately. For more information, see WILDCARDRESOLVE.

See also the EXCLUDWILDCARDOBJECTSONLY parameter.

Default

None

Syntax

```
TABLEEXCLUDE [container. | catalog.]owner.{table | sequence}
```

container. | catalog.

If the database requires three-part names, specifies the name or wildcard specification of the Oracle container or SQL/MX catalog that contains the object to exclude.

owner

Specifies the name or wildcard specification of the owner, such as the schema, of the object to exclude.
**TABLEEXCLUDE**

**table | sequence**

The name or wildcard specification of the object to exclude. To specify object names and wildcards correctly, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Example**

In this example, `test.tab*` specifies that all tables beginning with `tab` in schema `test` are to be excluded from all trail files. Table `fin.acct` is excluded from trail `ee`. Table `fin.sales` is excluded from trail `ff`.

```
TABLEEXCLUDE test.tab*
EXTTRAIL ./dirdat/ee
TABLE pdb1.*.*;
TABLEEXCLUDE pdb1.fin.acct
EXTTRAIL ./dirdat/ff
TABLE pdb2.*.*;
TABLEEXCLUDE pdb2.fin.sales
```
TARGETDB

Valid For

Replicat

Description

Use the TARGETDB parameter for databases or data sets that require a data source name or identifier to be specified explicitly as part of the connection information. This option is required to identify one of the following:

- The target login database for heterogeneous databases.
- The target data source name (DSN) if Replicat uses ODBC to connect to the database.
- The target SQL/MX catalog

Tables specified in MAP statements that follow TARGETDB are assumed to be from the specified data source.

You might need to use the USERID or USERIDALIAS parameter in the TARGETDB parameter statement, depending on the authentication that is required for the data source.

For databases that allow authentication at the operating-system level, you can specify TARGETDB without USERID or USERIDALIAS.

For DB2 LUW, the TARGETDB statement must refer to the database by its real name, rather than by any alias.

See USERID or USERIDALIAS for more information.

See also SOURCEDB to specify a source data source.

Default

None

Syntax

TARGETDB data_source[, SESSIONCHARSET character_set]

data_source

The name of the database, catalog, or data source name.

For MySQL databases, you can use the format of TARGETDB database_name@host_name to avoid connection issues caused by the incorrect configuration of localhost in the local hosts file. If running MySQL on a port other than the default of 3306, you must specify the port number in the connect string: TARGETDB database_name@host_name:port.

SESSIONCHARSET character_set

Supports Sybase, Teradata and MySQL. Sets the database session character set for the process login session. This parameter overrides any SESSIONCHARSET that is specified in the GLOBALS file.
Examples

**Example 1**
This example shows TARGETDB without the USERIDALIAS parameter.

TARGETDB mydb

**Example 2**
This example shows TARGETDB with the USERIDALIAS parameter.

TARGETDB mydb, USERIDALIAS tiger2
TARGETDEFS

Valid For

Extract (primary and data pump)

Description

Use the TARGETDEFS parameter to specify a target-definitions file. A target-definitions file is needed in certain cascading configurations or when the target is an Enscribe file. TARGETDEFS names a file on the source system or on an intermediary system that contains data definitions of tables and files that exist on the target system. Specify at least one TARGETDEFS entry before the TABLE statements for which the targets are Enscribe files.

You can have multiple TARGETDEFS statements in the parameter file if more than one target-definitions file is needed for different definitions, for example if each TARGETDEFS file holds the definitions for a specific application.

To generate the target-definitions file, use the DEFGEN utility. Transfer the file to the source or intermediary system before starting Extract.

See Administering Oracle GoldenGate for Windows and UNIX for more information about using data-definitions files.

Default

None

Syntax

TARGETDEFS file

file
The relative or fully qualified path name of the target-definitions file.

Examples

Example 1
TARGETDEFS C:\repodbc\sales.def

Example 2
TARGETDEFS /ggs/dirdef/ODBC/tandem_defs
TCPSOURCETIMER | NOTCPSOURCETIMER

Valid For

Extract

Description

Use the TCPSOURCETIMER and NOTCPSOURCETIMER parameters to manage the timestamps of replicated operations for reporting purposes within the Oracle GoldenGate environment.

TCPSOURCETIMER and NOTCPSOURCETIMER are global parameters and apply to all TABLE statements in the Extract parameter file.

Default

TCPSOURCETIMER

Syntax

TCPSOURCETIMER | NOTCPSOURCETIMER

TCPSOURCETIMER

Adjusts the timestamp of data records when they are sent to other systems, making it easier to interpret synchronization lag. This is the default.

NOTCPSOURCETIMER

Retains the original timestamp value. Use NOTCPSOURCETIMER when using timestamp-based conflict resolution in a bidirectional configuration and when using a user token that refers to ‘GGHEADER’, ‘COMMITTIMESTAMP’ of the @GETENV column-conversion function.
THREADOPTIONS

Valid For

Extract

Description

Use the THREADOPTIONS parameter to control how a threaded Extract operates. Stop and restart GGSCI, Manager, and Extract for the change to take effect.

Default

None

Syntax

THREADOPTIONS
[IOLATENCY milliseconds]
[INQUEUESIZE n]
[OUTQUEUESIZE n]

INQUEUESIZE n
Specifies the number of queue entries in the input queue of each producer Extract thread in an Oracle RAC cluster. Higher values produce better performance for large amounts of data. Lower values move data more quickly in environments with very little activity. Valid values are 16 to 65535. The default is 128. The default should be adequate in most cases, but if you need to increase it, 1000 should be sufficient in most types of environments. See also OUTQUEUESIZE.

In addition to INQUEUESIZE and OUTQUEUESIZE, AIX users might obtain better performance by setting the environment variable AIXTHREAD_SCOPE to S (system scope) which specifies the use of multiple CPUs so that processes can run concurrently. To use system scope, add the following to the .profile file of the user who starts the Manager process or else export the variable manually before starting GGSCI.

AIXTHREAD_SCOPE=S
export AIXTHREAD_SCOPE

IOLATENCY milliseconds
Specifies the amount of time between the database-configured max commit propagation delay and the internal value used by Oracle GoldenGate. Valid values are between 0 and 180000 milliseconds (3 minutes). The default is 1500 (1.5 seconds) to account for internal I/O latency. Not valid when Extract is in Archived Log Only mode (ALO).

OUTQUEUESIZE n
Specifies the number of queue entries in the output queue of each producer Extract thread in an Oracle RAC cluster. Valid values are 8 to 65535. The default is 2048. The default should be adequate in most cases.
TRACE | TRACE2

Valid For
Extract and Replicat

Description
Use the TRACE and TRACE2 parameters to capture Extract or Replicat processing information to help reveal processing bottlenecks. Both support the tracing of DML and DDL.

Tracing also can be turned on and off by using the SEND EXTRACT or SEND REPLICAT command in GGSCI. See "SEND EXTRACT" on page 1-37 or "SEND REPLICAT" on page 1-72.

Contact Oracle Support for assistance if the trace reveals significant processing bottlenecks.

Default
No tracing

Syntax
TRACE | TRACE2
[, DDL[INCLUDE] | DDLONLY]
[, [FILE] file_name]
[, THREADS {threadID[, threadID][[, ...]][, thread_range[, thread_range][[, ...]]]}

TRACE
Provides step-by-step processing information.

TRACE2
Identifies the code segments on which Extract or Replicat is spending the most time.

DDL[INCLUDE] | DDLONLY
(Replicat only) Enables DDL tracing and specifies how DDL tracing is included in the trace report.

DDL[INCLUDE]
Traces DDL and also traces transactional data processing. This is the default.
Either DDL or DDLINCLUDE is valid.

DDONLY
Traces DDL but does not trace transactional data.

[FILE] file_name
The relative or fully qualified name of a file to which Oracle GoldenGate logs the trace information. The FILE keyword is optional, but must be used if other parameter options will follow the file name, for example:

TRACE FILE file_name DDLINCLUDE

If no other options will follow the file name, the FILE keyword can be omitted, for example:

TRACE DDLINCLUDE file_name
THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])
    Enables tracing only for the specified thread or threads of a coordinated Replicat. Tracing is only performed for threads that are active at runtime.

    threadID[, threadID][, ...]
    Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

    [, thread_range[, thread_range][, ...]]
    Specifies a range of threads in the format of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

If the Replicat is in coordinated mode and TRACE is used with a THREADS list or range, a trace file is created for each currently active thread. Each file name is appended with its associated thread ID. This method of identifying trace files by thread ID does not apply when SEND REPLICAT is issued by groupname with threadID (as in SEND REPLICAT fin003 TRACE...) or when only one thread is specified with THREADS.

Contact Oracle Support for assistance if the trace reveals significant processing bottlenecks.

Examples

Example 1
The following traces to a file named trace.trc. If this is a coordinated Replicat group, the tracing applies to all active threads.

TRACE /home/ggs/dirrpt/trace.trc

Example 2
The following enables tracing for only thread 1. In this case, because only one thread is being traced, the trace file will not have a threadID extension. The file name is trace.trc.

TRACE THREADS(1) FILE ./dirrpt/trace.trc

Example 3
The following enables tracing for threads 1, 2, and 3. Assuming all threads are active, the tracing produces files trace001, trace002, and trace003.

TRACE THREADS(1-3) FILE ./dirrpt/trace.trc
TRACETABLE | NOTRACETABLE

Valid For

Extract and Replicat

Description

Use the TRACETABLE and NOTRACETABLE parameters with Oracle databases to identify a trace table that was created with the ADD TRACETABLE command. TRACETABLE is required only if the trace table was created with a name other than the default of GGS_TRACE. If a trace table named GGS_TRACE exists in the database, trace table functionality is enabled automatically, and TRACETABLE is not required.

A trace table is not used when Replicat is in integrated mode. TRACETABLE and NOTRACETABLE are ignored in that mode.

The trace table is used for bidirectional synchronization to identify Replicat transactions to Extract.

If used, TRACETABLE must appear in both the Extract and Replicat parameter files.

- In the Replicat parameter file, TRACETABLE causes Replicat to write an operation to the trace table at the beginning of each transaction.
- In the Extract parameter file, TRACETABLE causes Extract to identify as a Replicat transaction any transaction that begins with an operation on the trace table.

NOTRACETABLE prevents Replicat from writing an operation to the trace table, thus preventing Extract from recognizing Replicat transactions.

To control whether Replicat transactions are extracted by Extract or ignored, use the GETREPLICATES and IGNOREREPLICATES parameters. See “GETREPLICATES | IGNOREREPLICATES” on page 3-152 for more information.

For instructions on configuring bidirectional synchronization, see the Administering Oracle GoldenGate for Windows and UNIX.

Default

GGS_TRACE

Syntax

TRACETABLE [catalog.]owner.table | NOTRACETABLE

[catalog.]owner.table
The catalog (if stored in a consolidation database), owner, and name of the trace table.

Examples

Example 1
This example shows a two-part name.

TRACETABLE ggs.excl_trans

Example 2
This example shows a three-part name.
TRACEABLE user.ggs.excl_trans
**TRAILBYTEORDER**

**Valid For**

GLOBALs

**Description**

Use the TRAILBYTEORDER parameter in the GLOBALs file to set the byte format of the metadata in the trails or files created with the EXTFILE, EXTTRAIL, RMTFILE, and RMTTRAIL parameters. By default, Extract always writes the trail metadata in big endian byte order, regardless of the byte order of the source or target machine.

This parameter affects only the metadata of the trail records. It does not affect the column data.

When used in the GLOBALs file, TRAILBYTEORDER affects all of the files or trails in the same Oracle GoldenGate instance. To specify the byte order of a specific trail or file, use the TRAILBYTEORDER option of the associated EXTFILE, RMTFILE, EXTTRAIL, or RMTTRAIL parameter in the Extract parameter file. In cases where Extract writes to multiple trails or files on different platforms, TRAILBYTEORDER in the Extract parameter file enables the correct byte ordering of each one. When TRAILBYTEORDER is used as an Extract parameter, it overrides any TRAILBYTEORDER specification in the GLOBALs file.

TRAILBYTEORDER reduces the overhead of conversion work when the source and target machines both use little endian. In this case, because the default without TRAILBYTEORDER is BIGENDIAN, the conversion work must be performed from little endian to big endian (to write to trail) and then from big endian to little endian to read the trail on the target. TRAILBYTEORDER prevents unnecessary conversions by allowing you to specify the byte order that is used by both the source and target machines (LITTLEENDIAN) as the byte order of the trail.

In the case where the source byte order is big endian and the target is little endian, where some conversion is required, you can decide whether the conversion takes place at the source or at the target. To perform the conversion on the source, set TRAILBYTEORDER to LITTLEENDIAN. The trail is converted to little endian, and no conversion is needed on the target. To perform the conversion on the target, leave the default set to BIGENDIAN. If the target system of the trail is big endian, TRAILBYTEORDER is not needed, because the default is big endian.

Use the NATIVEENDIAN option for a primary Extract or a data pump if the byte order of the source machine is not known, but you want to keep that format and do not want conversion performed on the source. If nothing is specified with TRAILBYTEORDER, a data pump writes the trail using the same byte order as the input trail, which may not be the desired format.

TRAILBYTEORDER is valid for files that have a FORMAT RELEASE version of at least 12.1. For older versions, this parameter is ignored.

TRAILBYTEORDER is not valid for trails or files written by a data-pump Extract that is processing in PASSTHRU mode. In that mode, the records are passed to the remote trail without any modification. TRAILBYTEORDER is not valid if FORMATASCII, FORMATSQl, or FORMATXML is being used.

Do not use TRAILBYTEORDER when replicating data to a NonStop system. On the NonStop platform, Oracle GoldenGate only supports BIGENDIAN, the default.

To identify the byte order of the metadata in a trail, use the ENV command of the Logdump utility.
Default

BIGENDIAN

Syntax

TRAILBYTEORDER {BIGENDIAN | LITTLEENDIAN | NATIVEENDIAN}

BIGENDIAN
Formats the trail metadata in big endian.

LITTLEENDIAN
Formats the trail metadata in little endian.

NATIVEENDIAN
Formats the trail metadata in the default byte order of the local system. Enables you to make certain the output trail is converted to the native format of the source machine.

Example

TRAILBYTEORDER LITTLEENDIAN
**TRAILCHARSET**

**Valid For**
Replicat

**Description**

Use the TRAILCHARSET parameter to supply a character set for the source data if the trail is written by an Extract version that is earlier than 11.2.1.0.0. In the earlier versions, the source character set is not stored in the trail.

When TRAILCHARSET is used, Replicat uses the specified character set as the source character set when converting character-type columns to the target character set. Replicat issues a warning message when it uses the TRAILCHARSET character set.

By default, Replicat performs character set conversion. This feature is controlled by the CHARSETCONVERSION (default) and NOCHARSETCONVERSION parameters. To use TRAILCHARSET, NOCHARSETCONVERSION cannot be used.

**Default**
Character set of the operating system

**Syntax**

TRAILCHARSET source_charset [, REPLACEBADCHAR];

source_charset
The ICU character-set identifier or an Oracle character-set identifier of the source database. For Oracle databases, Oracle GoldenGate converts an Oracle identifier to the corresponding ICU identifier for conversion to the character set that is specified with the NLS_LANG specification in the SETENV parameter in the Replicat parameter file.

REPLACEBADCHAR
Prevents Replicat from abending when a conversion attempt fails. The failed character is replaced with a replacement character for each target character set. The replacement character is pre-defined in each character set.

**Examples**

**Example 1**
TRAILCHARSET ISO-8859-9;

**Example 2**
TRAILCHARSET windows-932, REPLACEBADCHAR;

**Example 3**
TRAILCHARSET EUC-CN;
TRAILCHARSETASCII

Valid For

Extract for DB2 on z/OS

Description

Use TRAILCHARSETASCII to cause character data to be written to the trail file in the local ASCII code page of the DB2 subsystem from which data is to be captured.

- Specification of this parameter on a single-byte DB2 z/OS subsystem causes character data from non-Unicode tables to be written to the trail file in the installed ASCII single-byte CCSID. Data from EBCDIC tables is converted to this ASCII CCSID.

- Specification of this parameter on a multi-byte DB2 z/OS subsystem causes Extract to process only ASCII and Unicode tables. Extract abends with an error if it encounters EBCDIC tables. Data from ASCII tables is written to the trail file in the installed ASCII mixed CCSID.

Either TRAILCHARSETASCII or TRAILCHARSETEBCDIC is required if the target is a multi-byte system. To replicate both ASCII and EBCDIC tables to a multi-byte DB2 z/OS target, process each character set with a different Oracle GoldenGate processing stream: one Extract, data pump, and Replicat for the ASCII tables and another Extract, data pump, and Replicat for the EBCDIC tables.

Default

Character data is written in the character set of the host table.

Syntax

TRAILCHARSETASCII
TRAILCHARSETEBCDIC

Valid For

Extract for DB2 on z/OS

Description

Use TRAILCHARSETEBCDIC to cause character data to be written to the trail file in the local EBCDIC code page of the DB2 subsystem from which data is to be captured.

- Specification of this parameter causes all character data to be written to the trail file in the EBCDIC code page of the job in which Extract is running.
- Specification of this parameter on a single-byte DB2 z/OS subsystem causes character data from non-Unide tables to be written to the trail file in the installed EBCDIC single-byte CCSID. Data from ASCII tables is converted to this EBCDIC CCSID.
- Specification of this parameter on a multi-byte DB2 z/OS subsystem causes Extract to process only EBCDIC and Unide tables. Extract abends with an error if it encounters ASCII tables. Data from EBCDIC tables is written to the trail file in the installed EBCDIC mixed CCSID.

Either TRAILCHARSETASCII or TRAILCHARSETEBCDIC is required if the target is a multi-byte system. To replicate both ASCII and EBCDIC tables to a multi-byte DB2 z/OS target, process each character set with a different Oracle GoldenGate processing stream: one Extract, data pump, and Replicat for the ASCII tables and another Extract, data pump, and Replicat for the EBCDIC tables.

Default

Character data is written in the character set of the host table.

Syntax

TRAILCHARSETEBCDIC
**TRANLOGOPTIONS**

**Valid For**
Extract

**Description**
Use the `TRANLOGOPTIONS` parameter to control the way that Extract interacts with the transaction log or with the API that passes transaction data, depending on the database or capture mode. You can use multiple `TRANLOGOPTIONS` statements in the same parameter file, or you can specify multiple options within the same `TRANLOGOPTIONS` statement, if permissible for those options.

Use a given `TRANLOGOPTIONS` option only for the database or databases for which it is intended.

**Default**
None

**Syntax**

```
TRANLOGOPTIONS {
   [{ACTIVATIONIDPADLEN | DATABASEIDPADLEN | THREADPADLEN | SEQPADLEN |
   RESETLOGSIDPADLEN} width]
   [ACTIVEDGFETCHTIMEOUT seconds]
   [ACTIVESECONDARYTRUNCATIONPOINT | MANAGESECONDARYTRUNCATIONPOINT |
   NOMANAGESECONDARYTRUNCATIONPOINT]
   [ALLOWDATALOSS]
   [ALLOWTABLECOMPRESSION]
   [ALTARCHIVEDLOGFORMAT string] [INSTANCE instance] [THREADID id]
   [ALTARCHIVELOGDEST [PRIMARY] [INSTANCE instance] path]
   [ALTARCHIVELOGDEST ('path' FILESPEC 'file_pattern')
    [NOT] RECURSIVE [PRIMARY]]
   [ALTLOGDEST path]
   [ARCHIVEDLOGONLY]
   [(ASMBUFSIZE size | DBLOGREADERBUFSIZE size)]
   [ASMUSER SYS@ASM_instance, ASMPASSWORD password
    [algorithm ENCRYPTKEY {key_name | DEFAULT}]
   [ASMUSERALIAS alias [DOMAIN domain]]
   [ASYNCTRANSPROCESSING buffer_size | NOASYNCTRANSPROCESSING]
   [BUFSIZE size]
   [CHECKPOINTRETENTIONTIME days]
   [CHECKTABLELEVELSUPPLOG]
   [COMPLETEARCHIVEDLOGONLY]
   [COMPLETEARCHIVEDLOGTIMEOUT seconds]
   [DBLOGREADER]
   [DBLOGREADERBUFSIZE size]
   [EXCLUDETAG [tag | NULL] | [EXCLUDETAG +]
   [EXCLUDETRANS transaction]
   [EXCLUDEUSER user]
   [EXCLUDEUSERID Oracle_uid]
   [FETCHLOBIFERROR]
   [FETCHPARTIALLOB]
   [FETCHPARTIALXML]
   [FILTERTABLE table]
   [FORCEFETCHLOB]
   
```
TRANLOGOPTIONS

[VAMCOMPATIBILITY {1 | 2 | 3}]
}
[, ...]

{ACTIVATIONIDPADLEN | DATABASEIDPADLEN | THREADPADLEN | SEQPADLEN | RESETLOGSIDPADLEN} width
(Oracle) Valid for Extract in classic capture mode

Specifies the minimum default padding length when Extract forms the archive log name using the format specifiers %A, %D, %T, %S, and %R in the ALTARCHIVERLOGFORMAT parameter. When the corresponding number is smaller than the field width, it is zero-padded on the left. Table 3–35 shows the specifier that relates to each option and the default length.

<table>
<thead>
<tr>
<th>Option</th>
<th>Specifier</th>
<th>Default padding length</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTIVATIONIDPADLEN</td>
<td>%A</td>
<td>8</td>
</tr>
<tr>
<td>DATABASEIDPADLEN</td>
<td>%D</td>
<td>8</td>
</tr>
<tr>
<td>THREADPADLEN</td>
<td>%T</td>
<td>3 on Windows, 4 on other platforms</td>
</tr>
<tr>
<td>SEQPADLEN</td>
<td>%S</td>
<td>5 on Windows, 10 on other platforms</td>
</tr>
<tr>
<td>RESETLOGSIDPADLEN</td>
<td>%R</td>
<td>10</td>
</tr>
</tbody>
</table>

ACTIVEDGFETCHTIMEOUT seconds
(Oracle) Valid for Extract in classic capture mode
Sets the interval, in seconds, after which Extract times out if v$database.current_scn has not moved past the commit SCN associated with the record for which it needs to issue a fetch within this timeout interval. The default is 600 seconds. Supports Extract in classic capture mode when capturing in an Oracle Data Guard environment.

**ACTIVEMANAGESECONDARYTRUNCATIONPOINT | MANAGESECONDARYTRUNCATIONPOINT | NOMANAGESECONDARYTRUNCATIONPOINT**

(SQL Server and Sybase) Controls the way that the secondary truncation point is managed.

**ACTIVESECONDARYTRUNCATIONPOINT**
Valid for SQL Server, not supported for Sybase.

Use **ACTIVESECONDARYTRUNCATIONPOINT** if Extract will not be running concurrently with SQL Server transactional replication or any non-Oracle Change Data Capture (CDC) implementation, and if non-native SQL Server log backups are taken against the database. It enables Extract to manage the secondary truncation point by marking transactions as distributed once they have been captured. Unlike when in **MANAGESECONDARYTRUNCATIONPOINT** mode, Extract in **ACTIVESECONDARYTRUNCATIONPOINT** mode does not read from transaction log backups. Therefore, you can use any third-party transaction-log backup software. Because only one Extract manages the secondary truncation point in this configuration, do not use **ACTIVESECONDARYTRUNCATIONPOINT** if there are multiple Extract groups capturing from the same database.

**MANAGESECONDARYTRUNCATIONPOINT**
Valid for SQL Server and Sybase.

**SQL Server usage:** Use **MANAGESECONDARYTRUNCATIONPOINT** if Extract will not be running concurrently with SQL Server transactional replication or any non-Oracle CDC implementation. It enables Oracle GoldenGate to maintain the secondary truncation point by means of a high-water mark, wherein any transactions older than this mark are considered distributed.

This method requires that the database transaction logs be available and readable by Extract. See *Installing and Configuring Oracle GoldenGate for SQL Server* for transaction log backup requirements. If using this parameter with at least one Extract in a multi-Extract configuration for the same database, it must be used for all of the Extract groups.

**Sybase usage:** Use **MANAGESECONDARYTRUNCATIONPOINT** if Extract will not be running concurrently with Sybase Replication Server. It enables Extract to manage the secondary truncation point.

**NOMANAGESECONDARYTRUNCATIONPOINT**
Valid for SQL Server and Sybase.

**SQL Server usage:** Use **NOMANAGESECONDARYTRUNCATIONPOINT** if Extract will be running concurrently with SQL Server transactional replication or any non-Oracle CDC implementation. Allows SQL Server replication to manage the secondary truncation point. If using this parameter with at least one Extract in a multi-Extract configuration for the same database, it must be used for all of the Extract groups.

**Sybase usage:** Use **NOMANAGESECONDARYTRUNCATIONPOINT** when you do not want to truncate the Sybase transaction log. Extract will not manage the secondary truncation point. You can use this option when Extract must re-read the Sybase transaction log from a previous log position for debugging purposes.
ALLOWDATALOSS
(Oracle) Valid for Extract in classic capture mode.

Enables classic Extract to continue processing when errors occur due to invalid redo records. By default, Extract abends on these errors, which can cause data loss if not processed.

ALLOWTABLECOMPRESSION
(DB2 LUW version 9.7 and earlier)

Enables Oracle GoldenGate to support tables created with row compression, as long as the tables do not contain LOBs. When this parameter is set, LOB columns are not supported, whether or not the table is compressed. To capture from a source where some tables have row compression and some do not, process the compression-enabled tables with one Extract group and the non-compressed tables with another Extract group.

ALTARCHIVEDLOGFORMAT string [INSTANCE instance] [THREADID id]
(Oracle) Valid for Extract in classic capture mode.

Specifies a string that overrides the archive log format of the source database.

In an Oracle RAC environment, use the ALTARCHIVEDLOGFORMAT parameter on each node. To ensure that Extract can differentiate between the log streams, use the INSTANCE or THREADID option. The default log format that is queried from the database for one RAC thread is assumed for all of the other threads if Extract cannot find a log format and nothing is specified with INSTANCE or THREADID.

**Note:** As an alternative to using INSTANCE or THREADID, you can specify a unique log directory for each thread with the ALTARCHIVELOGDEST option. Using a unique directory is recommended, even with a log name format that uses a thread specifier.

The TRANLOGOPTIONS statement that includes ALTARCHIVEDLOGFORMAT cannot contain any other TRANLOGOPTIONS options. Use a separate TRANLOGOPTIONS statement to specify other options.

**string**

Accepts the same specifier as Oracle’s parameter LOG_ARCHIVE_FORMAT. Extract uses the supplied format specifier to derive the log file name. Example:

```
arch_%t.arc
```

**INSTANCE instance**

For use with Oracle RAC. Applies ALTARCHIVEDLOGFORMAT to a specific Oracle instance. Extract verifies the supplied input against the database catalog.

Example:

```
TRANLOGOPTIONS ALTARCHIVEDLOGFORMAT &
INSTANCE rac1 log_%t_%s_%r.arc
```

**THREADID id**

For use with Oracle RAC. Specifies the thread number of the instance that has the specified log format.

Example:

```
TRANLOGOPTIONS ALTARCHIVEDLOGFORMAT &
```
TRANLOGOPTIONS

THREADID 2 log_%t_%s_%r.arc

ALTARCHIVELOGDEST [PRIMARY] [INSTANCE instance]
[THREADID id] path
(Oracle) Valid for Extract in classic capture mode.

Points Extract to the archived or backup Oracle transaction logs when they reside somewhere other than the default location. Extract first checks the specified location and then checks the default location.

You can specify more than one ALTARCHIVELOGDEST parameter for an Oracle instance. In that case, Extract searches each one in the order that is specified with ALTARCHIVELOGDEST.

For example, in the following excerpt from a parameter file, Extract searches under /disk1/node1/arch for logs related to instance rac1 and then under /disk2/node1/arch if the first search fails. Extract does not check the default location for rac1. For rac2, it checks /disk1/node2/arch, then the default location.

TRANLOGOPTIONS ALTARCHIVELOGDEST PRIMARY INSTANCE rac1 /disk1/node1/arch,
ALTARCHIVELOGDEST INSTANCE rac1 /disk2/node1/arch,
ALTARCHIVELOGDEST INSTANCE rac2 /disk1/node2/arch

path
Specifies the fully qualified path to the archived logs in the alternate directory. This directory must be NFS mounted to the node where Oracle GoldenGate is running. Use that mount point for ALTARCHIVELOGDEST.

PRIMARY
Prevents Extract from checking the default log location if it does not find the log in the alternate location. Only the ALTARCHIVELOGDEST path is checked. PRIMARY is the default for an Extract that is running in Archived Log Only (ALO) mode; otherwise, it is optional.

INSTANCE instance
Applies the specified ALTARCHIVELOGDEST behavior to a specific Oracle instance. On RAC, if this option is used, you must specify the ALTARCHIVELOGDEST parameter on each node.

THREADID id
Applies the specified ALTARCHIVELOGDEST behavior to a specific thread number.

ALTARCHIVELOGDEST ("path" [FILESPEC "file_pattern"]
[[NOT] RECURSIVE])
(SQL Server)

Extract reads from SQL Server transaction log backups out of this location instead of querying the msdb tables for the log backup location. Use this parameter if the log backups have been moved from their original destination.

Enclose the parameter arguments within parentheses. There can be only one
TRANLOGOPTIONS ALTARCHIVELOGDEST entry in a SQL Server Extract parameter file. If there are multiple entries, only the last one will be used.

"path"
Specifies the path name, in double quotes, to the log backups. You can use wildcard symbols after the last backslash (\) delimiter. An asterisk (*) matches zero or more characters. A question mark (?) matches exactly one character.
Do not use this option if using NOT RECURSIVE.

FILESPEC "file_pattern"
Specifies a file pattern within the backup path specified by "path". Enclose the file pattern within double quotes. An asterisk (*) matches zero or more characters. A question mark (?) matches exactly one character.

Do not use a backslash (\) delimiter. A backslash allows another path to be specified, which is invalid.

[NOT] RECURSIVE
Specifies whether or not the files specified by "path" are searched recursively (all sub-directories also searched).

ALTLOGDEST path
(MySQL)
Specifies the location of the MySQL log index file. Extract looks for the log files in this location instead of the database default location. ALTLOGDEST can be used when the database configuration does not include the full path name to the logs or when there are multiple MySQL installations on the machine. Extract reads the log index file to find the binary log file that it needs to read. When ALTLOGDEST is used, Extract assumes that the logs and the index are in the same location.

Supply the full path name to the directory. On Windows, enclose the path within double quotes if the path contains any spaces, such as in the following example.

TRANLOGOPTIONS  ALTLOGDEST "C:\Program Files\MySQL\MySQL Server 5.1\log\test.index"

ARCHIVEDLOGONLY
(Oracle) Valid for Extract in classic capture mode.

ARCHIVEDLOGONLY causes Extract to read from the archived logs exclusively, without querying or validating the logs from system views such as v$log and v$archived_log. This parameter puts Extract into Archived Log Only mode (ALO). By default, Extract does not use archived log-only mode even if the database that it connects to is a physical standby database. For more information about archived-log only mode, see Installing and Configuring Oracle GoldenGate for Oracle Database.

ASMBUFSIZE size
(Oracle) Valid for Extract in classic capture mode.

Controls the maximum size, in bytes, of a read operation into the internal buffer that holds the results of each read of the transaction log. Use this option instead of the DBLOGREADERBUFSIZE option if the source Oracle version is one that is:

■ 11g that is earlier than 11.2.0.2
■ any Oracle 11g R1 version

These versions do not support the newer API that is available in Oracle versions that are supported by the DBLOGREADER option. It is recommended that you use the DBLOGREADER option together with the DBLOGREADERBUFSIZE option if supported by your Oracle version.

Higher values increase extraction speed but cause Extract to consume more memory. Low values reduce memory usage but increase I/O because Extract must store data that exceeds the cache size to disk.

The following are the valid ranges and default sizes, in bytes:
Minimum: size of one block in the redo log

Maximum: 4 MB

Default: 2 MB (2097152)

The value of the BUFSIZE option must always be at least equal to, or greater than, the value of DBLOGREADERBUFSIZE.

ASMUSER SYS@ASM_instance, ASMPASSWORD password [algorithm
ENCRIPTKEY (key_name | DEFAULT)]

(Oracle) Valid for Extract in classic capture mode.

Specifies credentials for logging in to an ASM instance to read the transaction logs. Can be used instead of ASMUERALIAS if an Oracle GoldenGate credential store is not being used.

SYS@ASM_instance
Specifies the ASM instance for the connection string. The user must be SYS.

password
Is the encrypted password that is copied from the ENCRYPT PASSWORD command results.

algorithm
Specifies the encryption algorithm that was used to encrypt the password: AES128, AES192, AES256, or BLOWFISH.

ENCRIPTKEY key_name
Specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if ENCRYPT PASSWORD was used with the KEYNAME key_name option.

ENCRIPTKEY DEFAULT
Directs Oracle GoldenGate to use a random key. Use if ENCRYPT PASSWORD was used with the KEYNAME DEFAULT option.

Note: This parameter does not replace the standard USERID parameter. Both are required in an ASM environment. ASMUSER is not needed if using the DBLOGREADER option to read the logs.

See Administering Oracle GoldenGate for Windows and UNIX for more information about password security features.

ASMUERALIAS alias [DOMAIN domain]
(Oracle) Valid for Extract in classic capture mode.

Specifies credentials for logging in to an ASM instance to read the transaction logs. Can be used instead of ASMUSER if an Oracle GoldenGate credential store is being used.

alias
Specifies the alias of the login credential that will be used to log into the ASM instance. This credential must exist in the Oracle GoldenGate credential store. If you are not sure what alias to use, you can inspect the content of the credential store by issuing the INFO CREDENTIALSTORE command. See "INFO CREDENTIALSTORE" on page 1-103.

DOMAIN domain
Specifies the domain that is assigned to the specified alias in the credential store.
For more information about the credential store, see *Administering Oracle GoldenGate for Windows and UNIX*.

**Note:** This parameter does *not* replace the standard USERIDALIAS parameter. Both are required in an ASM environment. ASMUSERALIAS is not needed if using the DBLOGREADER option to read the logs.

**ASYNCTRANSPROCESSING buffer_size | NOASYNCTRANSPROCESSING**  
(Oracle) Valid for Extract in integrated capture mode.

Controls whether integrated capture runs in asynchronous or synchronous processing mode, and controls the buffer size when Extract is in asynchronous mode.

**ASYNCTRANSPROCESSING buffer_size**  
The default. In asynchronous transaction processing mode, there are two threads of control:

- One thread groups logical change records (LCR) into transactions, does object-level filtering, and does partial rollback processing,
- The other thread formats committed transactions, performs any user-specified transformations, and writes to the trail file.

The transaction buffer is the buffer between these two threads and is used to transfer work from one thread to the other. The default transaction buffer size is 300 committed transactions, but is adjusted downward by the Oracle GoldenGate memory manager if its cache memory is close to being exhausted.

**NOASYNCTRANSPROCESSING**  
Disables asynchronous processing and causes Extract to operate in synchronous mode. In this mode, one thread performs all capture work.

**BUFSIZE size**  
(DB2 LUW, DB2 z/OS, Oracle)

Controls the maximum size, in bytes, of the buffers that are allocated to contain the data that is read from the transaction log.

- For an Oracle source where Extract is processing file-based redo, this parameter also controls the maximum size, in bytes, of a read operation into the buffer.
- For an Oracle source where Extract is processing ASM redo, TRANLOGOPTIONS with either ASMBUFSIZE or DBLOGREADERBUFSIZE controls the read size, and in both cases BUFSIZE controls the buffer size. This parameter must be equal to, or greater than, the value that is set for ASMBUFSIZE or DBLOGREADERBUFSIZE (depending on which is in use.)

High values increase capture speed but cause Extract to consume more memory. Low values reduce memory usage but increase I/O because Extract must store data that exceeds the cache size to disk.

The following are the valid ranges and default sizes, in bytes:

**Oracle:**

- Minimum: 8,192
- Maximum: 10,000,000

The default buffer size is determined by the source of the redo data:
For file-based redo, the default is 1000KB (1024000).

For ASM redo, the default is 1000KB (1024000).

For DBLOGREADER redo, the default is 2MB (2097152).

For Extract in integrated capture mode, the default is 1000KB (1024000).

**DB2 LUW:**

- Minimum: 40,960
- Maximum: 33,554,432
- Default: 131,072
- The preceding values must be in multiples of the 4096 page size. Extract will truncate to a multiple if a given value does not meet this requirement.
- Check with the Systems Administrator to make sure that there is enough ECSA space to support the new buffer size.

**CHECKPOINTRETENTIONTIME** days
(Oracle) Valid for Extract in both classic and integrated mode.

Controls the number of days that Extract retains checkpoints before they are purged. Partial days can be specified using decimal values. For example, 8.25 specifies 8 days and 6 hours. When the checkpoint of an Extract in integrated capture mode is purged, LogMiner data dictionary information for the archived redo log file that corresponds to the checkpoint is purged, and the first_scn value of the capture process is reset to the SCN value corresponding to the first change in the next archived redo log file. The default is seven days. For more information about capture checkpoints, see Oracle Database XStream Guide.

**CHECKTABLELEVELSUPPLOG**
(Oracle) Valid for Extract in classic capture mode.

Causes Extract to send a warning to the report file if it encounters a table for which the ADD TRANDATA command was not issued to create an Oracle GoldenGate supplemental log group. CHECKTABLELEVELSUPPLOG also verifies whether the key columns in any user-defined log groups for the table are the same as, or a superset of, the key columns of the log group that was created with the ADD TRANDATA command. Without key columns, Extract may abend or try to fetch the missing column or columns. By default, CHECKTABLELEVELSUPPLOG verification is disabled.

**COMPLETEARCHIVEDLOGONLY | NOCOMPLETEARCHIVEDLOGONLY**
(Oracle) Valid for Extract in classic capture mode.

Overrides the default Extract processing of archived logs. This parameter applies when copying production (source) archive logs to a secondary database where they will serve as the data source. Some Oracle programs do not build the archive log from the first byte to the last byte in sequential order, but instead may copy the first 500MB, then the last 500MB, and finally the middle 1000MB, for example. If Extract begins reading at the first byte, it will abend when it reaches the break in the byte sequencing. Waiting for the whole file to be written prevents this problem.

Note that Extract starts to read an archive file before it is completely written to disk, but whether or not it starts to capture data before the file is complete depends on whether COMPLETEARCHIVEDLOGONLY or NOCOMPLETEARCHIVEDLOGONLY is used.
**COMPLETEARCHIVEDLOGONLY**
This is the default in ALO (archived log only) mode. It forces Extract to wait for the archived log to be written to disk completely before starting to process redo data. In regular mode, use it to override the default of NOCOMPLETEARCHIVEDLOGONLY.

**NOCOMPLETEARCHIVEDLOGONLY**
This is the default in regular mode. Extract starts processing redo data from an archived log immediately when it becomes available, without waiting for it to be written completely to disk. In ALO mode, use it to override the default of COMPLETEARCHIVEDLOGONLY.

**COMPLETEARCHIVEDLOGTIMEOUT seconds**
(Oracle) Valid for Extract in classic capture mode.
Controls the number of seconds that Extract waits, when in COMPLETEARCHIVEDLOGONLY mode, to try again if it cannot validate that a redo log is being completely written to disk. Use this option in conjunction with the COMPLETEARCHIVEDLOGONLY option of TRANLOGOPTIONS. This option is disabled by default, and Extract will abend after ten seconds if it cannot validate that the file is being written to disk. This check is performed by reading the block header from the last block and verifying against the expected sequence number to determine if the last block has been written out. For seconds use any value greater than 0.

**DBLOGREADER**
(Oracle) Valid for Extract in classic capture mode.
Causes Extract to use a newer API that is available as of Oracle 11.2.0.2 and later 11g R2 versions. This API uses the database server to access the redo and archive logs. DBLOGREADER can be used to mine logs on regular disks and raw disks, and can be used instead of connecting directly to an Oracle ASM instance. The database system must contain the libraries that contain the API modules and must be running. To use this feature, the Extract database user must have SELECT ANY TRANSACTION privilege.

When used, DBLOGREADER enables Extract to use a read size of up to 4 MB in size. This is controlled with the DBLOGREADERBUFSIZE option. The maximum read size when using the default OCI buffer is 28672 bytes. This is controlled by the ASMBUFSIZE option. A larger buffer may improve the performance of Extract when redo rate is high.

When using DBLOGREADER with ASM, do not use the ASMUSER or ASMUSERALIAS and ASMPASSWORD options of TRANLOGOPTIONS. The API uses the user and password specified with the USERID or USERIDALIAS parameter. For more information about using Oracle GoldenGate with ASM, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

**DBLOGREADERBUFSIZE size**
(Oracle) Valid for Extract in classic capture mode.

Controls the maximum size, in bytes, of a read operation into the internal buffer that holds the results of each read of the transaction log in ASM. High values increase capture speed but cause Extract to consume more memory. Low values reduce memory usage but increase I/O because Extract must store data that exceeds the cache size to disk.

Use DBLOGREADERBUFSIZE together with the DBLOGREADER option if the source ASM instance is Oracle 11.2.0.2 and later 11g R2 versions. The newer ASM API in those versions provides better performance than the older one. If the Oracle version is not one of those versions, then ASMBUFSIZE must be used.
The following are the valid ranges and default sizes, in bytes:

- Minimum: size of one block in the redo log
- Maximum: 4 MB
  
  On AIX, the maximum buffer size is 1048576; any attempt to read more than this maximum will result in error.
- Default: 2 MB (2097152)

The default should be sufficient in most cases.

The value of the `BUFSIZE` option must always be at least equal to, or greater than, the value of `DBLOGREADERBUFSIZE`.

```
[EXCLUDETAG [tag | NULL] | [EXCLUDETAG +]
```

(Oracle) Valid for Extract in integrated or classic mode; primary or data pump.

Use `EXCLUDETAG tag` to direct the Extract process to ignore the individual records that are tagged with the specified redo tag. There is no database release limitation for this parameter though not all releases of Oracle Database support tagging. Compare with older versions, new trail file contains tag tokens, which would not introduce problems for older trail readers.

Use `EXCLUDETAG +` to direct the Extract process to ignore the individual records that are tagged with any redo tag.

To tag the individual records, use the `DBOPTIONS` parameter with the `SETTAG` option in the Replicat parameter file. Use these parameters to prevent cycling (loop-back) of Replicat the individual records in a bi-directional configuration or to filter other transactions from capture. The default `SETTAG` value is 00. Valid value is any single Oracle Streams tag or a plus sign (+). A tag value can be up to 2000 hexadecimal digits (0-9 A-F) long. The `dbms_streams.set_tag` operation is supported by `EXCLUDETAG`. For more information about Streams tags, see Oracle Streams Replication Administrator's Guide.

`EXCLUDETRANS transaction`

(Sybase, SQL Server)

Specifies the transaction name of the Replicat database user or any other user so that those transactions are not captured by Extract. Use for bi-directional processing to prevent data looping between the databases.

The default transaction name used by Replicat is `ggs_repl`, but any transaction can be specified with `EXCLUDETRANS`. For more information about bidirectional synchronization, see Administering Oracle GoldenGate for Windows and UNIX.

`EXCLUDEUSER user`

(DB2 LUW, DB2 z/OS, Oracle, Sybase)

Specifies the name of the Replicat database user, or of any other user, to be used as a filter that identifies transactions that will be subject to the rules of the `GETREPLICATES` or `IGNOREREPLICATES` parameter. Typically, this option is used to identify Replicat transactions in a bi-directional or cascading processing configuration, for the purpose of excluding or capturing them. However, it can be used to identify transactions by any other user, such as those of a specific business application.

You can use `EXCLUDEUSER` and `EXCLUDEUSERID` in the same parameter file. Do not use wildcards in either parameter.

The user name must be valid. Oracle GoldenGate queries the database to get the associated user ID and maps the numeric identifier back to the user name. For this
reason, if the specified user is dropped and recreated while name resolution is set to the default of DYNAMICRESOLUTION, EXCLUDEUSER remains valid. If the same transaction is performed when name resolution is set to NODYNAMICRESOLUTION, EXCLUDEUSER becomes invalid, and Extract must be stopped and then started to make EXCLUDEUSER take effect. See "DYNAMICRESOLUTION | NODYNAMICRESOLUTION" on page 3-115 for more information.

■ **DB2 z/OS considerations:** In DB2 for z/OS, the user is always the primary authorization ID of the transaction, which is typically that of the original RACF user who logged on, but also could be a different authorization ID if changed by a transaction processor or by DB2 exits.

■ **Oracle considerations:** For an Oracle database, multiple EXCLUDEUSER statements can be used. All specified users are considered the same as the Replicat user, in the sense that they are subject to the rules of GETREPLICATES or IGNOREREPLICATES.

**EXCLUDEUSERID Database_uid**

(Informix, Oracle) Valid for Extract.

Specifies the database user ID (uid) of the Replicat database user, or of any other user, to be used as a filter that identifies transactions that will be subject to the rules of the GETREPLICATES or IGNOREREPLICATES parameter. The GETREPLICATES or IGNOREREPLICATES parameters are not supported on Informix.

Usage is the same as that of EXCLUDEUSER.

Oracle_uid is a non-negative integer with a maximum value of 2147483638. There are several system views that can be queried to get the user ID. The simplest one is the ALL_USERS view. Oracle GoldenGate does not validate the user ID. If the user that is associated with the specified user ID is dropped and recreated, a new user ID is assigned; therefore, EXCLUDEUSERID becomes invalid for that user.

**FETCHLOBIFERROR**

(Oracle) Valid for Extract in classic capture mode.

Overrides the Extract default of abending if LOB capture from the redo log results in an error, such as incomplete data. It forces Extract to fetch the LOB from the database if there is an error when reading it from the redo log.

---

**Caution:** If a value gets deleted before the fetch occurs, Extract writes a null to the trail. If a value gets updated before a fetch, Extract writes the updated value. To prevent these inaccuracies, try to keep Extract latency low. See *Administering Oracle GoldenGate for Windows and UNIX* guidelines for tuning process performance. Also, see "FETCHOPTIONS" on page 3-131 for instructions on setting fetch options.

---

See also the FORCEFETCHLOB option.

**FETCHPARTIALLOB**

(Oracle) Valid for Extract in integrated capture mode.

Use this option when replicating to a non-Oracle target or in other conditions where the full LOB image is required. It causes Extract to fetch the full LOB object, instead of using the partial change object from the redo record. By default, the database logmining server sends Extract a whole or partial LOB, depending on whether all or part of the source LOB was updated. To ensure the correct snapshot of the LOB, the Oracle Flashback feature must be enabled for the table and Extract must be configured
to use it. The Extract `FETCHOPTIONS` parameter controls fetching and must be set to `USESNAPSHOT` (the default in the absence of `NOUSESNAPSHOT`). Without a Flashback snapshot, Extract fetches the LOB from the table, which may be a different image from the point in time when the redo record was generated.

**FETCHPARTIALXML**  
(Oracle) Valid for Extract in integrated capture mode.

Use this option when replicating to a non-Oracle target or in other conditions where the full LOB image is required. It causes Extract to fetch the full XML document, instead of using the partial change image from the redo record. By default, the database log mining server sends Extract a whole or partial XML document, depending on whether all or part of the source XML was updated. To ensure the correct snapshot of the XML, the Oracle Flashback feature must be enabled for the table and Extract must be configured to use it. The Extract `FETCHOPTIONS` parameter controls fetching and must be set to `USESNAPSHOT` (the default in the absence of `NOUSESNAPSHOT`). Without a Flashback snapshot, Extract fetches the XML document from the table, which may be a different image from the point in time when the redo record was generated.

**FILTERNABLE** *table*  
(Extract for MySQL and SQL/MX)

Use this option to specify the fully qualified name of the checkpoint table being used by Replicat. Operations on the checkpoint table will be ignored by the local Extract as a means of preventing data from looping back to the source. For information about creating a checkpoint table, see *Administering Oracle GoldenGate for Windows and UNIX*. To specify object names and wildcards correctly, see *Administering Oracle GoldenGate for Windows and UNIX*.

**FORCEFETCHLOB**  
(Oracle) Valid for Extract in classic and integrated capture modes.

Overrides the default behavior of capturing LOB data from the redo log. Causes LOBs to be fetched from the database by default.

---

**Caution:** If a value gets deleted before the fetch occurs, Extract writes a null to the trail. If a value gets updated before a fetch, Extract writes the updated value. To prevent these inaccuracies, try to keep Extract latency low. The Oracle GoldenGate documentation provides guidelines for tuning process performance. Also, see *Installing and Configuring Oracle GoldenGate for Oracle Database* for instructions on setting fetch options.

---

**GETCTASDML | NOGETCTASDML**  
Enables Create Table As Select (CTAS) functionality. When `GETCTASDML` is enabled, CTAS DMLs are sent from LogMiner and replicated on the target. Execution of the CTAS DDL is suppressed on the target. This parameter cannot be enabled while using the DDL metadata trigger. Trail files produced with the CTAS functionality enabled cannot be consumed by a Replicat version lower than 12.1.2.1.0.

Use `GETCTASDML` to allow CTAS to replay the inserts of the CTAS thus preserving OIDs during replication. This parameter is only supported with Integrated Dictionary and any downstream Replicat must be 12.1.2.1 or greater to consume the trail otherwise, there may be divergence.

**HANDLEDLFAILOVER**  
(Oracle) Valid for integrated Extract only.
TRANLOGOPTIONS

Controls whether Extract will throttle its writing of trail data based on the apply progress of the Fast Start Failover standby database. It is intended to keep Extract at a safe point behind any data loss failover. When using this for data loss in a Data Guard configuration with Fast Start Failover (FSFO), after a role transition you must set the FAILOVERTARGETDESTID Extract parameter to identify the archive log destination ID to where the standby can be connected.

IGNOREDATACAPTURECHANGES | NOIGNOREDATACAPTURECHANGES
(DB2 LUW)

Controls whether or not Extract captures tables for which DATA CAPTURE CHANGES is not set. IGNOREDATACAPTURECHANGES ignores tables for which DATA CAPTURE CHANGES is not set. Use if tables were specified with a wildcard to ensure that processing continues for tables that do have change capture set. A warning is issued to the error log for tables that were skipped. The default is NOIGNOREDATACAPTURECHANGES.

IGNOREDIRECTLOADINSERTS
(Oracle) Valid for Extract in classic capture mode.

Causes Extract to ignore all Oracle direct-load INSERTs. The default behavior (without this parameter) is to capture Oracle direct-load INSERTs. This option applies to Oracle logs with log compatibility of Oracle 10g or later.

INCLUDEAUX (AUX_specification)
Directs the Oracle GoldenGate VAMSERV component to capture only the specified AUX trails when reading the audit trail. This parameter can improve performance when you know that some AUX trails will not contain data that is to be captured and can be ignored. With this parameter, you specify only the AUX trails that are to be captured.

AUX_specification is a number that represents the AUX trails to be captured. To specify multiple AUX trails, use a comma-delimited list. For example, the following statement includes AUX trails BB & CC = 1, 2.

TRANLOGOPTIONS INCLUDEAUX (1, 2)

To only include MAT or to exclude all AUX trails, place one space between the parentheses, for example:

TRANLOGOPTIONS INCLUDEAUX ( )

INCLUDEREGIONID | INCLUDEREGIONIDWITHOFFSET
(Oracle) Valid for Extract in either capture mode.

These options support the Oracle data type TIMESTAMP WITH TIME ZONE specified as TZR (which represents the time zone region, such as US/Pacific). By default, Extract abends on TIMESTAMP WITH TIME ZONE if it includes a time zone region. These options enable you to handle this timestamp based on the target database type.

When Extract detects that the source data type is TIMESTAMP and there is a region ID mapping token, Replicat applies the timestamp as follows:

- A TIMESTAMP WITH TIME ZONE with TZR is applied if the target Oracle version supports it.
- A timestamp with a UTC offset is applied to a non-Oracle database, or to an earlier version of Oracle that does not support TIMESTAMP WITH TIME ZONE with TZR.

INCLUDEREGIONID

Use when replicating from an Oracle source to an Oracle target of the same version or later. When INCLUDEREGIONID is specified, Extract adds a column index
and the two-byte TMZ value as a time-zone mapping token and outputs it to the trail in the UTC format of YYYY-MM-DD HH:MI.SS.FFFFFF +00:00.

**INCLUDEREGIONIDWITHOFFSET**
Use when replicating TIMESTAMP WITH TIME ZONE as TZR from an Oracle source that is v10g or later to an Oracle target that is earlier than 10g, or from an Oracle source to a target that is not an Oracle database. When INCLUDEREGIONIDWITHOFFSET is specified, Extract converts the time zone region value to a time offset that takes Daylight Saving Time into account based on the date and time. The timestamp data is written to the trail in local time in the format of YYYY-MM-DD HH:MI.SS.FFFFFF TZH:TZM, where TZH:TZM is the region ID converted time offset.

**INTEGRATEDPARAMS (parameter value [, ...])**
(Oracle) Valid for Extract in integrated capture mode (Oracle Standard or Enterprise Edition 11.2.0.3 or later)

Passes parameters and values to the Oracle database logmining server when Extract is in integrated capture mode. The input must be in the form of parameter value, as in:

TRANLOGOPTIONS INTEGRATEDPARAMS (downstream_real_time_mine Y)

Valid parameter specifications and their values are the following:

- **max_sga_size**
  Specifies the amount of SGA memory that is used by the database logmining server. Can be a positive integer in megabytes. The default is 1 GB if streams_pool_size is greater than 1 GB; otherwise, it is 75% of streams_pool_size.

- **parallelism**
  Specifies the number of processes supporting the database logmining server. Can be a positive integer. The default is 2.

- **downstream_real_time_mine**
  Specifies whether or not integrated capture mines a downstream mining database in real-time mode. A value of Y specifies real-time capture and requires standby redo logs to be configured at the downstream mining database. A value of N specifies capture from archived logs shipped to the downstream mining database. The default is N.

**LEGACYLOBREADING**
Valid for SQL Server and Sybase.

Causes the VAM module to use the LOB storage mechanism that was used in Extract versions 11.1.x or earlier. A different LOB storage mechanism is used starting with version 11.2.1.

**LOGRETENTION [ENABLED [DAYS n] | SR | DISABLED]**
(Oracle Enterprise Edition) Valid for Extract in classic capture mode.

Specifies whether or not Oracle Recovery Manager (RMAN) retains the log files that Extract needs for recovery. When you use the REGISTER EXTRACT command, the logs are retained from the time that the command is issued, based on the current database SCN. The logs are retained until manually deleted. This parameter does not enable or disable RMAN within the database itself.

Other information about LOGRETENTION:

- If the Oracle flash recovery storage area is full, RMAN will purge the archive logs even when needed by Extract. This limitation exists so that the requirements of
Extract (and other Oracle replication components) do not interfere with the availability of redo to the database.

- The database user that is assigned to Extract and specified with the USERID or USERIDALIAS parameter must have certain privileges, which are the same as those required for the DBLOGIN parameter. See "DBLOGIN" on page 1-116 for more information.

- LOGRETENTION makes use of an underlying (but non-functioning) Oracle Streams Capture process; thus, it requires the database to be the Enterprise Edition of Oracle version 11g or higher. Oracle Standard Edition and Express Edition do not support this feature. The LOGRETENTION feature can operate concurrently with other Streams installations.

---

**Note:** To support RMAN log retention on Oracle RAC, you must download and install the database patch that is provided in BUGFIX 11879974, before you add the Extract groups.

---

**ENABLED [DAYS n]**

Enables the log-retention feature. This is the default, except when Extract for an Oracle database is in Archived Log Only (ALO) mode. Extract must be registered with the database by using the REGISTER EXTRACT command with the LOGRETENTION option.

By default, ENABLED honors the SCN of the Bounded Recovery checkpoint and retains the logs up to and including that point. This checkpoint represents the log file of the oldest open non-persisted transaction. In the unlikely event that a problem with Bounded Recovery affects the persisted data, the logs that are required to reprocess the oldest open transaction must be available.

You can use the DAYS option to retain the logs for a specific number of days, from 1 to 365 days as a whole number. The default for DAYS is 7 days.

To be more conservative, you can use the SR option instead. See "BR" on page 3-33 for more information about the Bounded Recovery feature.

**SR**

Enables the log-retention feature, but retains logs up to and including the SCN of the log that is required for Extract to revert to standard (normal) recovery mode. In normal mode, Extract needs access to the log that contains the oldest open transaction that it had in memory. Using SR is a conservative measure that retains more logs than would be retained in Bounded Recovery mode (the default), but it ensures data availability in case Bounded Recovery fails. Extract must be registered with the database by using the REGISTER EXTRACT command with the LOGRETENTION option.

**DISABLED**

Disables the log-retention feature. This is the default setting when Extract for an Oracle source is operating in Archived Log Only (ALO) mode, but you can override this if needed. If you used the REGISTER EXTRACT command to register Extract, use the UNREGISTER EXTRACT command to unregister the associated Extract group from the database after disabling log retention. See "UNREGISTER EXTRACT" on page 1-55 for more information.

**LOGSOURCE platform, [PATHMAP path]**

(Oracle) Valid for Extract in classic capture mode.
Specifies the operating system and (optionally) the path name when the redo and/or archived logs are stored on a platform other than the one which is hosting the database. When LOGSOURCE is used, put the entire TRANLOGOPTIONS statement on one line. Do not use ampersand (&) line terminators to split it into multiple lines.

**platform**
Specifies the platform that hosts the redo or archived logs. Valid values are:

- AIX
- HPUX
- LINUX
- MVS
- SOLARIS
- VMS
- WINDOWS
- S390

To maintain correct data alignment, the specified platform and the platform that Extract is running on must have the same endian order and bit width (as in 32-bit or 64-bit). The following are compatible endian platforms:

- Big endian: AIX, HPUX, MVS, SOLARIS, S290
- Little endian: LINUX, VMS, WINDOWS

For example when running Extract on HPUX, a LOGSOURCE platform setting of AIX is valid but LINUX is not.

**PATHMAP path**
Specifies the path to the logs.

**MAXREADESIZE records**
Valid for Sybase.

Specifies how many records Extract will read from the transaction log at one time. Can be used to improve performance. Valid values are integers from 1 through 50000. The default is 256 records. Be careful when adjusting this parameter to very high values. It will reduce the frequency at which Extract adjusts the secondary truncation point, and log data can accumulate. Start with 10000 and evaluate performance before adjusting upward.

**MAXWARNEOF seconds**
(Oracle) Valid for Extract in classic capture mode.

Specifies the number of seconds that Extract waits for a new log file to become available before generating a warning message. Extract generates only one warning message for a given sequence number. If MAXWARNEOF is not specified, Extract waits for one hour by default. A value of 0 omits the warning no matter how long Extract waits.

**MINEFROMACTIVEDG**
(Oracle) Valid for Extract in classic capture mode.

Specifies that Extract is allowed to mine redo from an Active Data Guard instance. Without this parameter set, Extract will abend with an error. Supports Extract in classic capture mode when capturing in an Oracle Data Guard environment.
**MININGUSER** (/ | user) [, **MININGPASSWORD** password]

```
[algorithm ENCRYPTKEY {key_name | DEFAULT}] [SYSDBA]
```

(Oracle) Valid for Extract in integrated capture mode.

Specifies login credentials for Extract to log in to a downstream Oracle mining database to interact with the logmining server. Can be used instead of the **MININGUSERALIAS** option if an Oracle GoldenGate credential store is not being used.

This user must:

- Have the privileges granted in `dbms_goldengate_auth.grant_admin_privilege`.
- Be the user that issues the `MININGDBLOGIN` or `MININGDBLOGINALIAS` and `REGISTER EXTRACT` or `UNREGISTER EXTRACT` commands for the Extract group that is associated with this **MININGUSERALIAS**.
- Not be changed while Extract is in integrated capture mode.

```
/
```

Directs Oracle GoldenGate to use an operating-system login for Oracle, not a database user login. Use this argument only if the database allows authentication at the operating-system level. Bypassing database-level authentication eliminates the need to update Oracle GoldenGate parameter files if application passwords frequently change.

To use this option, the correct user name must exist in the database, in relation to the value of the Oracle `OS_AUTHENT_PREFIX` initialization parameter. The value set with `OS_AUTHENT_PREFIX` is concatenated to the beginning of a user's operating system account name and then compared to the database name. Those two names must match.

When `OS_AUTHENT_PREFIX` is set to `' '` (a null string), the user name must be created with `IDENTIFIED EXTERNALLY`. For example, if the OS user name is `ogg`, you would use the following to create the database user:

```
CREATE USER ogg IDENTIFIED EXTERNALLY;
```

When `OS_AUTHENT_PREFIX` is set to `OPS$` or another string, the user name must be created in the format of:

```
OS_AUTHENT_PREFIX_value OS_user_name
```

For example, if the OS user name is `ogg`, you would use the following to create the database user:

```
CREATE USER ops$ogg IDENTIFIED BY oggpassword;
```

**user**

Specifies the name of the mining database user or a SQL*Net connect string.

**password**

The user’s password. Use when database authentication is required to specify the password for the database user. If the password was encrypted by means of the `ENCRYPT PASSWORD` command, supply the encrypted password; otherwise, use the clear-text password. If the password is case-sensitive, type it that way. If either the user ID or password changes, the change must be made in the Oracle GoldenGate parameter files, including the re-encryption of the password if necessary.

**algorithm**

Specifies the encryption algorithm that was used to encrypt the password with `ENCRYPT PASSWORD`. Can be one of:
ENCRTKEY (key_name | DEFAULT)
Specifies the encryption key that was specified with ENCRYPT PASSWORD.

- ENCRYPTKEY key_name specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if ENCRYPT PASSWORD was used with the KEYNAME key_name option.
- ENCRYPTKEY DEFAULT directs Oracle GoldenGate to use a random key. Use if ENCRYPT PASSWORD was used with the KEYNAME DEFAULT option.

SYSDBA
Specifies that the user logs in as sysdba.

For more information about Oracle GoldenGate security options, see Administering Oracle GoldenGate for Windows and UNIX.

MINEFROMSNAPSHOTSTBY | NOMINEFROMSNAPSHOTSTBY
(Oracle) Controls whether or not Oracle GoldenGate can capture from redo that is archived by a snapshot standby database. MINEFROMSNAPSHOTSTBY enables Extract to run on a snapshot standby in classic capture mode or in integrated capture mode in an upstream configuration; running in a downstream configuration is not supported because the snapshot standby database does not ship its redo logs to another database.

The default is NOMINEFROMSNAPSHOTSTBY, which prevents Extract from capturing from a database that is a snapshot. Extract cannot run on a physical standby database and will abend if its source snapshot database is converted to a physical database.

MININGUSERALIAS alias
(Oracle) Valid for Extract in integrated capture mode.

Specifies the alias for the login credentials that Extract uses to log in to a downstream Oracle mining database to interact with the logmining server. Can be used instead of MININGUSER if an Oracle GoldenGate credential store is being used.

This alias must be:

- Associated with a database user login credential that is stored in the local Oracle GoldenGate credential store. For more information about the credential store, see Administering Oracle GoldenGate for Windows and UNIX. This user must have the privileges granted in dbms_goldengate_auth.grant_admin_privilege.
- The user that issues the MININGDBLOGIN or MININGDBLOGINALIAS and REGISTER EXTRACT or UNREGISTER EXTRACT commands for the Extract group that is associated with this MININGUSERALIAS.

This alias and user must not be changed while Extract is in integrated capture mode.

NODDLCHANGETWARNING
(SQL Server)
Forces Extract not to log a warning when a DDL operation is made to a source object for which Extract is capturing data. The default is to report a warning, so that the problem can be corrected. Oracle GoldenGate does not support DDL capture and replication for SQL Server, so it expects source and target metadata to remain constant. Some DDL changes do not cause Extract to abend, but the warning still will be logged...
whenever such changes occur. NODDLCHANGEWARN prevents those messages from accumulating in the Oracle GoldenGate log.

**NOFLUSH**

(DB2 z/OS)

Inhibits the flushing of log buffers.

**PATHMAP NFS_mount_point log_path**

(Oracle) Valid for Extract in classic capture mode.

Specifies the location of the redo and/or archived logs when they are stored on a system other than the one which is hosting the database. More than one PATHMAP statement can be used. When PATHMAP is used, put the entire TRANLOGOPTIONS statement on one line. Do not use ampersand (&) line terminators to split it into multiple lines.

PATHMAP can be used with the LOGSOURCE option if the system is a different platform from the one that hosts the database.

**NFS_mount_point**

Specifies the NFS mount point of the remote system where the logs are stored.

**log_path**

The path to the logs on the remote system. The path must follow the mount point specification.

**PREPAREFORUPGRADETOIE | NOPREPAREFORUPGRADETOIE**

(Oracle) Valid when upgrading from Classic to Integrated Extract on Oracle RAC.

When upgrading on Oracle RAC from Classic to Integrated Extract, you must set the PREPAREFORUPGRADETOIE option before stopping Classic Extract for the upgrade then wait for the information message in the report file that indicates that the parameter has taken effect before proceeding with the upgrade. For detailed upgrade instructions, see *Upgrading Oracle GoldenGate for Windows and UNIX*.

**PREPAREFORUPGRADETOIE**

Set PREPAREFORUPGRADETOIE in the Extract parameter file, which requires a restart of Extract, or you can set it dynamically for a running extract from GGSCI using this command:

```
SEND EXTRACT extract_name TRANLOGOPTIONS PREPAREFORUPGRADETOIE
```

**NOPREPAREFORUPGRADETOIE**

Dynamically turns off the PREPAREFORUPGRADETOIE option if necessary. The default is NOPREPAREFORUPGRADETOIE.

**PURGEORPHANEDTRANSACTIONS | NOPURGEORPHANEDTRANSACTIONS**

(Oracle) Valid for Extract in classic capture mode.

Controls the purging of orphaned transactions that occur when an Oracle RAC node fails and Extract cannot capture the rollback.

**PURGEORPHANEDTRANSACTIONS**

Purges orphaned transactions. A transaction is verified as orphaned before purging by comparing its startup time with the node’s startup time; if the transaction started earlier, it is purged.

**NOPURGEORPHANEDTRANSACTIONS**

The default. Orphaned transactions are not purged.
**QUERYRETRYCOUNT number**
(Extract for SQL Server)

Specifies how many times to retry a query to obtain table metadata after timeouts. Timeouts can occur for a long-running transaction that has created any table. The system tables become locked and prevent Extract's query from completing.

The default is one retry after a 30-second wait, after which the process abends if the retry fails. **QUERYRETRYCOUNT** can be specified to retry multiple times at 30-second intervals, according to the input value that is supplied. If all of the retries fail, Extract abends with the normal connection error message.

The following example causes Extract to attempt its query four times at 30-second intervals:

```
TRANLOGOPTIONS QUERYRETRYCOUNT 4
```

**READQUEUESIZE size**
Valid for Sybase.

Specifies the internal queue size, in bytes, for transaction data. It can be increased to improve performance. Valid values are integers from 10 through 50000. The default is 512 bytes. Start with 10000 and evaluate performance before adjusting upward.

**REQUIRELONGDATACAPTURECHANGES | NOREQUIRELONGDATACAPTURECHANGES**
(DB2 LUW)

Controls the response of Extract when DATA CAPTURE is set to NONE or to CHANGES without INCLUDE LONGVAR COLUMNS and the parameter file includes any of the following Oracle GoldenGate parameters that require the presence of before images for some or all column values: GETBEFOREUPDATES, NOCOMPRESSUPDATES, and NOCOMPRESSDELETES. Both of those DATA CAPTURE settings prevent the logging of before values for LONGVAR columns. If those columns are not available to Extract, it can affect the integrity of the target data.

**REQUIRELONGDATACAPTURECHANGES**
Extract abends with an error.

**NOREQUIRELONGDATACAPTURECHANGES**
Extract issues a warning but continues processing the data record.

**[TSLOOKUPBEGINLRI | TSLOOKUPENDLRI]**
(DB2 LUW v10.1 and later)

When you specify an LRI range using these parameters, Extract looks for the timestamp specified in the ADD or ALTER EXTRACT command within this range. This helps Extract to optimize the lookup process for a particular timestamp in the database transaction log. The **TSLOOKUPBEGINLRI** parameter is mandatory while **TSLOOKUPENDLRI** is optional. Specifying only **TSLOOKUPENDLRI** without **TSLOOKUPBEGINLRI** is invalid. For example:

```
TRANLOGOPTIONS TSLOOKUPBEGINLRI 75200.666197, TSLOOKUPENDLRI 75207.666216
TRANLOGOPTIONS TSLOOKUPBEGINLRI 75200.666197
```

If the provided timestamp falls between the given LRI ranges or the provided timestamp falls after the **TSLOOKUPBEGINLRI** LRI timestamp then Extract starts from a record with timestamp equal to or nearest less than the provided timestamp.

If the provided timestamp falls before **TSLOOKUPBEGINLRI** LRI timestamp, Extract is started from the specified **TSLOOKUPBEGINLRI** LRI. If the provided timestamp falls after **TSLOOKUPENDLRI** timestamp, then Extract abends. If you only specify **TSLOOKUPENDLRI**,
then an informational message is displayed and Extract starts from a record with
timestamp equal or nearest less than the provided timestamp.

**TRANSCLEANUPFREQUENCY** minutes
(Oracle) Valid for Extract in classic capture mode.

Specifies an interval, in minutes, after which Oracle GoldenGate scans for orphaned
transactions, and then scans again to delete them. The initial scan marks transactions
considered to be orphaned. The second scan confirms they are orphaned, and they are
deleted. Valid values are from 1 to 43200 minutes. Default is 10 minutes.

**USENATIVEOBJSUPPORT | NOUSENATIVEOBJSUPPORT**
(Oracle) Valid for Extract in integrated capture mode.

Integrated Capture adds redo-based capture for User Defined Type (UDT) and
ANYDATA data types. It is *not* enabled by default and can only be enabled if the source
database version is 12.1.0.1 or greater and the source database compatibility is
12.0.0.0.0 or greater. Replicat from Oracle GoldenGate release 12.1.2.1.0 must be used.
If a source or target database of release 12.1.0.1 is used, the Streams patch for bug
18038108 must be installed on the database. To use Native Support, all of your Oracle
databases and Oracle GoldenGate instances must be release 12.1.0.1 or greater to be
compatible.

If redo-based capture is enabled but a UDT contains an unsupported attribute,
Integrated Capture retries to capture the UDT using fetch. For limitations of support
for capture, see *Installing and Configuring Oracle GoldenGate for Oracle Database*. If you
create object tables by using a `CREATE TABLE AS SELECT` (CTAS) statement, Integrated
Capture must be configured to capture DML from CTAS operation in order to fully
support object tables. For CTAS use information, see *Installing and Configuring Oracle
GoldenGate for Oracle Database*

The default is **NOUSENATIVEOBJSUPPORT**, meaning that Integrated Capture uses
fetch-based capture for UDT and ANYDATA by default (as with Classic Capture).

**USEPREVRESETLOGSID | NOUSEPREVRESETLOGSID**
(Oracle) Valid for Extract in classic capture mode.

Specifies that Extract will take the previous `RESETLOG` id as the current branch. The
default is **NOUSEPREVRESETLOGSID**. Supports Extract in classic capture mode when
capturing in an Oracle Data Guard environment.

**VAMCOMPATIBILITY {1 | 2}**
(MySQL, SQL M/X, SQL Server, Sybase, Teradata)

Ensures the VAM module and the VAM API are using the same version of the column
metadata structure. As new features are added to the VAM API, the column metadata
needs enhancing with new attributes. When this occurs a new version is created,
adding the new column metadata attributes to the existing ones. All database
implementations other than Teradata are required to update to the latest version after
a new version is added.

1
A value of one means the original VAM API metadata structure is being used. This
structure was originally created for Teradata, which is a separate implementation
from the other databases, and only Teradata still uses this level. To maintain
backwards compatibility with Extract, it may be necessary to manually set
**VAMCOMPATIBILITY** to 1 if running an earlier version of a TAM module against later
releases of Extract that contain VAM versioning. Extract abends with a message to
the report file if **VAMCOMPATIBILITY** 1 is required and not set.
This VAM version added column metadata attributes for SQL Server. This value is set internally by the VAM module, so setting it manually with `TRANLOGOPTIONS` is not required.

This is the current version level. All databases other than Teradata (including SQL Server) use this level and set it internally in the VAM module, so setting it manually with `TRANLOGOPTIONS` is not required.

### Examples

#### Example 1
The following specifies the location of the archived logs.

```
TRANLOGOPTIONS ALTARCHIVELOGDEST /fs1/oradata/archive/log2
```

#### Example 2
The following Oracle example filters for two users (one by name and one by user ID). The transactions generated by these users will be handled according to the `GETREPLICATES` or `IGNOREREPLICATES` rules, and a new transaction buffer size is specified.

```
TRANLOGOPTIONS EXCLUDEUSER ggsrep, EXCLUDEUSERID 90, BUFSIZE 100000
```

#### Example 3
The following excludes the Replicat transaction name in a SQL Server or Sybase environment.

```
TRANLOGOPTIONS EXCLUDETRANS ggs_repl
```

#### Example 4
The following shows how to deal with transaction logs that are on a platform other than the one which hosts the database.

```
TRANLOGOPTIONS, LOGSOURCE VMS, PATHMAP
DKA200: [RDBMS.ORACLE.ORA9201I.64.ADMIN.GGS.ARCH]
/net/deltan/uservol1/RDBMS.DIR/ORACLE.DIR/ORA9201I.DIR/64.DIR/admin.DIR/ggs.DIR/ARCH.dir PATHMAP
DKA200: [RDBMS.ORACLE.ORA9201I.64.ORADATA.GGS]
/net/deltan/uservol1/rdbms.dir/oracle.dir/ora9201I.DIR/64.dir/oradata.dir/ggs.dir
```

#### Example 5
The following example supplies ASM credentials by specifying the alias `asm1` in the `asmdomain` domain in the Oracle GoldenGate credential store.

```
TRANLOGOPTIONS ASMUSERALIAS asm1 DOMAIN asmdomain
```

**Note:** The following statement spans multiple lines only because of space constraints in this documentation.
Example 6
The following is an example of how to specify the padding width when Extract forms the archive log name using the format specifiers %T, %S, and %R in the ALTARCHIVELOGFORMAT parameter.

TRANLOGOPTIONS ALTARCHIVELOGFORMAT ARC_%S_%R.%T
TRANLOGOPTIONS SEQPADLEN 12, RESETLOGSIDPADLEN 12, THREADPADLEN 5

Example 7
The following are examples of how to use tag specifiers with EXCLUDETAG.

TRANLOGOPTIONS EXCLUDETAG 00
TRANLOGOPTIONS EXCLUDETAG +
TRANLOGOPTIONS EXCLUDETAG 0952
TRANSACTIONTIMEOUT

Valid For

Replicat

Description

Use the TRANSACTIONTIMEOUT parameter to prevent an uncommitted Replicat target transaction from holding locks on target tables and consuming database resources unnecessarily. You can change the value of this parameter so that Replicat can work within existing application timeouts and other database requirements on the target.

TRANSACTIONTIMEOUT limits the amount of time that Replicat will hold a target transaction open if it has not received the end-of-transaction record for the last source transaction in that transaction. By default, Replicat groups multiple source transactions into one target transaction to improve performance, but it will not commit a partial source transaction and will wait indefinitely for that last record. The Replicat parameter GROUPTRANSOPS controls the minimum size of a grouped target transaction.

The following events could last long enough to trigger TRANSACTIONTIMEOUT:

■ Network problems prevent trail data from being delivered to the target system.
■ Running out of disk space on any system, preventing trail data from being written.
■ Collector abends (a rare event).
■ Extract abends or is terminated in the middle of writing records for a transaction.
■ An Extract data pump abends or is terminated.
■ There is a source system failure, such as a power outage or system crash.

How TRANSACTIONTIMEOUT Works

During normal operations, Replicat remembers the position in the trail of the beginning of the first source transaction in the current target transaction, in case the transaction must be abended and retried. When TRANSACTIONTIMEOUT is enabled, Replicat also saves the position of the first record of the current source transaction and will use that position as the logical end-of-file (EOF) if TRANSACTIONTIMEOUT is triggered.

When triggered, TRANSACTIONTIMEOUT does the following:

1. Aborts the current target transaction
2. Repositions to the beginning of the first source transaction in the aborted target transaction.
3. Processes all of the trail records up to the logical end-of-file position (the beginning of the last, incomplete source transaction).
4. Commits the transaction at logical EOF point.
5. Waits for new trail data before processing any more trail records.

TRANSACTIONTIMEOUT can be triggered multiple times for the same source transaction, depending on the nature of the problem that is causing the trail data to arrive slowly enough to trigger TRANSACTIONTIMEOUT.
Detecting a TRANSACTIONTIMEOUT Condition

To determine whether or not Replicat is waiting for the rest of a source transaction when TRANSACTIONTIMEOUT is enabled, issue the SEND REPLICAT command with the STATUS option. The following statuses indicate this condition:

- Performing transaction timeout recovery
- Waiting for data at logical EOF after transaction timeout recovery

Default

Disabled

Syntax

TRANSACTIONTIMEOUT \( n \) \( \text{units} \)

\( n \)
An integer that specifies the wait interval. Valid values are from one second to one week (seven days). This value should be greater than that set with the EOFDELAY parameter in both the primary Extract and any associated data pumps.

\( \text{units} \)
One of the following: S, SEC, SECS, SECOND, SECONDS, MIN, MINS, MINUTE, MINUTES, HOUR, HOURS, DAY, DAYS.

Example

TRANSACTIONTIMEOUT 5 S
Valid For

Extract for DB2 on z/OS

Description

Use the TRANSMEMORY parameter to control the amount of memory and temporary disk space available for caching uncommitted transaction data. Because Oracle GoldenGate sends only committed transactions to the target database, it requires sufficient system memory to store transaction data on the source system until either a commit or rollback indicator is received.

This parameter is for use with a DB2 database on z/OS database. For all other databases, use the CACHEMGR parameter.

About Memory Management with TRANSMEMORY

TRANSMEMORY enables you to tune the Oracle GoldenGate transaction cache size and define a temporary location on disk for storing data that exceeds the size of the cache. Options are available for defining the total cache size, the per-transaction memory size, the initial and incremental memory allocation, and disk storage space.

Transactions are added to the memory pool specified by RAM, and each is flushed to disk when TRANSRAM is reached. An initial amount of memory is allocated to each transaction based on INITTRANSRAM and is increased by the amount specified by RAMINCREMENT as needed, up to the maximum set with TRANSRAM. Consequently, the value for TRANSRAM should be evenly divisible by the sum of (INITTRANSRAM + RAMINCREMENT).

To view current TRANSMEMORY settings, use the VIEW REPORT command in GGSCI.

Special z/OS Considerations

On a z/OS system, the RAM option not only controls the total virtual memory allocation for all cached transactions, but also controls the size of the heap memory that is allocated during startup. The large default value prevents fragmentation within the virtual memory pool, but in some installations it could cause virtual memory to be wasted, especially if the applications primarily generate small transactions. Allocating a large amount of heap memory also can cause Extract to be unresponsive at startup until z/OS completes the allocation.

On z/OS, set RAM just large enough to hold enough transaction activity without affecting the performance of Extract. If set too low, it can cause Extract to write transaction data to disk, causing Extract to run more slowly and to consume disk space. You might need to do some testing to determine the optimal value.

Default

None

Syntax

TRANSMEMORY
[RAM size]
[TRANSRAM size]
[TRANSALLSOURCES size]
[INITTRANSRAM size]
[RAMINCREMENT size]
[DIRECTORY (directory, max_size, max_file_size)]

**RAM size**
Specifies the total amount of memory to use for all cached transactions. On z/OS this also is the initial amount of memory to allocate per transaction. The default is 200 megabytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

**TRANSRAM size**
Specifies the total amount of memory to use for a single transaction. The default is 50 megabytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

TRANSRAM should be evenly divisible by both INITTRANSRAM and RAMINCREMENT for optimal results.

**TRANSALLSOURCES size**
Specifies the total amount of memory and disk space to use for a single transaction. The default is 50% of total available memory (memory and disk). The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

**INITTRANSRAM size**
(NonStop system only) Specifies the initial amount of memory to allocate for a transaction. The default is 500 kilobytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

**RAMINCREMENT size**
Specifies the amount of memory to increment when a transaction requires more memory. The default is 500 kilobytes. The value can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | mb | kb | g | m | k

**DIRECTORY (directory, max size, max file size)**
Specifies temporary disk storage for transaction data when its size exceeds the maximum specified with TRANSRAM. You can specify DIRECTORY more than once.

The directory size specified with max_size and the file size specified with max_file_size must be greater than the size of the memory specified with RAM.

The names of the files that are created take one of the following formats, depending on the process type:

- group_trans_00001.mem takes the name of the group and indicates that an online process created the file.
- PID_trans_00001.mem takes the name of a process ID (PID) and indicates that a one-time process (specified with the SPECIALRUN parameter) created the file.
- group_thread#_00001.mem takes a group name and a thread number, indicating that a threaded Extract created the file.
directory
The fully qualified path name of a directory. The default is the dirtmp sub-directory of the Oracle GoldenGate directory.

max_size
The maximum size of all files in the directory. The default is 2 gigabytes. If the space specified is not available, then 75% of available disk space is used. Values can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | nb | kb | g | m | k

max_file_size
The maximum size of each file in the directory. The default is 200 megabytes. Values can be specified in bytes or in terms of gigabytes, megabytes, or kilobytes in any of the following forms:

GB | MB | KB | G | M | K | gb | nb | kb | g | m | k

Examples

Example 1
The following example allows per-transaction memory to be incremented ten times before data is flushed to disk, once for the initial allocation specified with INITTRANSRAM and then nine more times as permitted by RAMINCREMENT.

TRANSMEMORY DIRECTORY(c:\test\dirtmp, 3000000000, 3000000000), RAM 8000K, TRANSRAM 1000K, INITTRANSRAM 100K, RAMINCREMENT 100K

Example 2
The following is the same as the preceding example, but with the addition of a second directory.

TRANSMEMORY DIRECTORY(c:\test\dirtmp, 3000000000, 3000000000), DIRECTORY (c:\test\dirtmp2, 1000000000, 5000000), RAM 8000K, TRANSRAM 100K, INITTRANSRAM 100K, RAMINCREMENT 100K

Note: In the previous examples, the parameter specification spans multiple lines because of space constraints. In an actual parameter file, multi-line parameter specifications must contain an ampersand (&) at the end of each line.
TRIMSPACES | NOTRIMSPACES

Valid For

Extract and Replicat

Description

Use the TRIMSPACES and NOTRIMSPACES parameters to control whether or not trailing spaces in a source CHAR column are truncated when applied to a target CHAR or VARCHAR column. TRIMSPACES and NOTRIMSPACES can be used at the root level of the parameter file as global ON/OFF switches for different sets of TABLE or MAP statements, and they can be used within an individual TABLE or MAP statement to override any global settings for that particular MAP or TABLE statement.

Note: Sybase treats all CHAR types as VARCHAR types, and therefore TRIMSPACES will have no effect. For Sybase, use the TRIMVARSPACES parameter.

TRIMSPACES is applied only to single-byte white spaces (U+0020). Ideographic spaces (U+3000) are not supported.

For Extract, TRIMSPACES only has an effect if Extract is performing mapping within the TABLE statement (by means of a TARGET statement).

Default

TRIMSPACES

Syntax

TRIMSPACES | NOTRIMSPACES

Examples

Example 1
The following example uses TRIMSPACES and NOTRIMSPACES at the root level of the parameter file. The default of TRIMSPACES is in effect until the last MAP statement, to which NOTRIMSPACES applies.

MAP fin.src1, TARGET fin.tgt1;
MAP fin.src2, TARGET fin.tgt2;
MAP fin.src3, TARGET fin.tgt3;
NOTRIMSPACES
MAP fin.src4, TARGET fin.tgt4;

Example 2
The following example uses NOTRIMSPACES within a MAP statement to override the global default of TRIMSPACES. The default applies to the first two MAP statements, and then NOTRIMSPACES applies to the last two targets.

MAP fin.src1, TARGET fin.tgt1;
MAP fin.src1, TARGET fin.tgt2;
MAP fin.src1, TARGET fin.tgt3, NOTRIMSPACES;
MAP fin.src1, TARGET fin.tgt4, NOTRIMSPACES;
TRIMVARSPACES | NOTRIMVARSPACES

Valid For

Extract and Replicat

Description

Use the TRIMVARSPACES and NOTRIMVARSPACES parameters to control whether or not trailing spaces in a source VARCHAR column are truncated when applied to a target CHAR or VARCHAR column. TRIMVARSPACES and NOTRIMVARSPACES can be used at the root level of the parameter file as global ON/OFF switches for different sets of TABLE or MAP statements, and they can be used within an individual TABLE or MAP statement to override any global settings for that particular MAP or TABLE statement.

The default is NOTRIMVARSPACES because the spaces in a VARCHAR column can be part of the data. Before using TRIMVARSPACES, make certain that trailing spaces are not required as part of the target data.

For Extract, TRIMVARSPACES only has an effect if Extract is performing mapping within the TABLE statement (by means of a TARGET statement).

Default

NOTRIMVARSPACES

Syntax

TRIMVARSPACES | NOTRIMVARSPACES

Examples

Example 1
The following example uses TRIMVARSPACES and NOTRIMVARSPACES at the root level of the parameter file. The default of NOTRIMVARSPACES is in effect until the last MAP statement, to which TRIMVARSPACES applies.

```
MAP fin.src1, TARGET fin.tgt1;
MAP fin.src2, TARGET fin.tgt2;
MAP fin.src3, TARGET fin.tgt3;
TRIMVARSPACES
MAP fin.src4, TARGET fin.tgt4;
```

Example 2
The following example uses TRIMVARSPACES within a MAP statement to override the global default of NOTRIMVARSPACES. The default applies to the first two MAP statements, and then TRIMVARSPACES applies to the last two targets.

```
MAP fin.src1, TARGET fin.tgt1;
MAP fin.src1, TARGET fin.tgt2;
MAP fin.src1, TARGET fin.tgt3, TRIMVARSPACES;
MAP fin.src1, TARGET fin.tgt4, TRIMVARSPACES;
```
UPDATEDELETES | NOUPDATEDELETES

Valid For
Replicat

Description
Use the UPDATEDELETES parameter to convert delete operations to update operations for all MAP statements that are specified after it in the parameter file. Use NOUPDATEDELETES to turn off UPDATEDELETES. These parameters are table-specific. One remains in effect for subsequent MAP statements until the other is encountered.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the UPDATEDELETES threads in one set of MAP statements, and specify the NOUPDATEDELETES threads in a different set of MAP statements.

When using UPDATEDELETES, use the NOCOMPRESSDELETES parameter. This parameter causes Extract to write all of the columns to the trail, so that they are available for updates.

Default
NOUPDATEDELETES

Syntax
UPDATEDELETES | NOUPDATEDELETES

Example
This example shows how you can apply UPDATEDELETES and NOUPDATEDELETES selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

UPDATEDELETES
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
NOUPDATEDELETES
MAP sales.loc, TARGET sales.loc, THREAD (3);
UPDATEINSERTS | NOUPDATEINSERTS

Valid For
Replicat

Description
Use the UPDATEINSERTS parameter to convert insert operations to update operations for all MAP statements that are specified after it in the parameter file. Use NOUPDATEINSERTS to turn off UPDATEINSERTS.

Because you can selectively enable or disable these parameters between MAP statements, you can enable or disable them for different threads of a coordinated Replicat. Specify the UPDATEINSERTS threads in one set of MAP statements, and specify the NOUPDATEINSERTS threads in a different set of MAP statements.

Default
NOUPDATEINSERTS

Syntax
UPDATEINSERTS | NOUPDATEINSERTS

Example
This example shows how you can apply UPDATEINSERTS and NOUPDATEINSERTS selectively to different MAP statements, each of which represents a different thread of a coordinated Replicat.

UPDATEINSERTS
MAP sales.cust, TARGET sales.cust, THREAD (1);
MAP sales.ord, TARGET sales.ord, THREAD (2);
NOUPDATEINSERTS
MAP sales.loc, TARGET sales.loc, THREAD (3);
UPDATERECORDFORMAT

Valid For

Extract for all databases except Teradata.

Description

Use the UPDATERECORDFORMAT parameter to cause Extract to combine the before and after images of an UPDATE operation into a single record in the trail. This parameter is valid for Oracle databases versions 11.2.0.4 and later. It is valid for Extract in classic and integrated capture modes; it is valid for a master Extract though is not valid for pump Extract.

Before images are generated when the GETUPDATEBEFORES, GETBEFORECOLS, and LOGALLSUPCOLS parameters are used. (In the case of an update to a primary key, unique index, or user-specified KEYCOLS key, the before and after images are stored in the same record by default. UPDATERECORDFORMAT does not apply in these cases.) The NOCOMPRESSUPDATES parameter is required for non-Oracle databases.

When two records are generated for an update to a single row, it incurs additional disk I/O and processing for both Extract and Replicat. If supplemental logging is enabled on all columns, the unmodified columns may be repeated in both the before and after records. The overall size of the trail is larger, as well. This overhead is reduced by using UPDATERECORDFORMAT.

When UPDATERECORDFORMAT is used, Extract writes the before and after images to a single record that contains all of the information needed to process an UPDATE operation. In addition to improving the read performance of downstream processes, this enables column mapping functions to access the before and after column values at the same point in time, rather than having to cache the before image column values while reading the after values.

UPDATERECORDFORMAT takes effect for all TABLE statements in the parameter file.

If you specify both UPDATERECORDFORMAT and FORMAT RELEASE 11.x or earlier, then Extract will abend.

>Note: Many-columned tables can cause the trail record to reach its maximum size when UPDATERECORDFORMAT is used. The rest of the record is continued in one or more additional, chained record fragments. This has a minor effect on processing performance.

Default

UPDATERECORDFORMAT FULL

Syntax

UPDATERECORDFORMAT [FULL | COMPACT]

FULL

Generates one trail record that contains the before and after images of an UPDATE, where the before image includes all of the columns that are available in the transaction record for both the before and after images. This is the default. When viewed in the Logdump utility, this record appears as GGSUnifiedUpdate.
COMPACT
Generates one trail record that contains the before and after images of an UPDATE, where the before image includes all of the columns that are available in the transaction record, but the after image is limited to the primary key columns and the columns that were modified in the UPDATE. UPDATERECORDFORMAT COMPACT is recommended for configurations that include an integrated Replicat.

When either FULL or COMPACT are viewed in the Logdump utility, the record appears as GGSUnifiedUpdate. The record contains the following:

- a header
- the length of the before image
- the before values of each column
- the after values of the primary key, unique index, or KEYCOLS columns
- the after values of the modified columns
- internal token data

Example

UPDATERECORDFORMAT COMPACT
**UPREPORT**

**Valid For**
Manager

**Description**
Use the `UPREPORTMINUTES` or `UPREPORTHOURS` parameter to specify the frequency with which Manager reports Extract and Replicat processes that are running. Every time one of those processes starts or stops, events are generated. Those messages are easily overlooked in the error log because the log can be so large. `UPREPORTMINUTES` and `UPREPORTHOURS` report on a periodic basis to ensure that you are aware of the process status.

If `UPREPORT` is explicitly indicated and the value of the `CHECKMINUTES` parameter is greater than that of `UPREPORT`, then `CHECKMINUTES` acquires the value of `UPREPORT`.

To report on stopped processes, use the `DOWNREPORT` parameter. See "DOWNREPORT" on page 3-111 for more information.

**Default**
Do not report running processes

**Syntax**

```
UPREPORTMINUTES minutes | UPREPORTHOURS hours
```

- **UPREPORTMINUTES minutes**
  Sets the report frequency in minutes.

- **UPREPORTHOURS hours**
  Sets the report frequency in hours.

**Example**
The following generates a report every 30 minutes.

```
UPREPORTMINUTES 30
```
USEANSISQLQUOTES | NOUSEANSISQLQUOTES

Valid For

GLOBALS

Description

Use the USEANSISQLQUOTES and NOUSEANSISQLQUOTES parameters to control how Oracle GoldenGate treats column names and literals that are enclosed within single or double quote marks.

---

**Note:** When capturing and mapping object names, such as table names, Oracle GoldenGate always recognizes double-quoted strings as case-sensitive object names, regardless of whether USEANSISQLQUOTES or NOUSEANSISQLQUOTES is specified.

---

USEANSISQLQUOTES is the default behavior of Oracle GoldenGate. It directs Oracle GoldenGate to follow SQL-92 rules for using quotation marks. With USEANSISQLQUOTES enabled, Oracle GoldenGate treats a string within double quotes as a case-sensitive column name, and it treats a string within single quotes as a literal. For example, consider the behavior of the @STRLEN conversion function, which returns a string length. By default, Oracle GoldenGate interprets the double-quoted "ABC" as an upper-case column name, and @STRLEN returns the length of whatever the value is for column "ABC".

```plaintext
COLMAP ( TGT1 = @STRLEN("ABC") )
```

If the double quotes are changed to single quotes in the preceding example, Oracle GoldenGate interprets 'ABC' as a literal, and @STRLEN returns 3.

```plaintext
COLMAP ( TGT1 = @STRLEN('ABC') )
```

NOUSEANSISQLQUOTES is intended for backward compatibility with the parameter files of Oracle GoldenGate versions that predate version 12c, where strings in double quotes are intended to be literals and case-sensitive column names are not supported (whether or not they are within quotes). For example, consider the behavior of the @STRLEN conversion function, which returns a string length. With NOUSEANSISQLQUOTES, the following @STRLEN specification returns a value of 3 because Oracle GoldenGate interprets the double-quoted "ABC" as a literal.

```plaintext
COLMAP ( TGT1 = @STRLEN("ABC") )
```

When used, NOUSEANSISQLQUOTES affects all TABLE and MAP statements in the local Oracle GoldenGate instance.

Default

USEANSISQLQUOTES

Syntax

USEANSISQLQUOTES | NOUSEANSISQLQUOTES
Examples

Example 1
The following matrix shows the difference in the use of quote marks around input variables between the default of USEANSISQLQUOTES and NOUSEANSISQLQUOTES.

<table>
<thead>
<tr>
<th>Input Variable</th>
<th>USEANSISQLQUOTES</th>
<th>NOUSEANSISQLQUOTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Literal text</td>
<td>'text string'</td>
<td>&quot;text string&quot;</td>
</tr>
<tr>
<td>Unquoted column names in database</td>
<td>COLUMN1</td>
<td>COLUMN1</td>
</tr>
<tr>
<td>Quoted column name (Case is preserved by Oracle GoldenGate.)</td>
<td>&quot;Column1&quot;</td>
<td>Not supported. All names are converted to upper case.</td>
</tr>
</tbody>
</table>

Example 2
The following matrix shows how to escape literal single or double quote marks that are part of literal input.

<table>
<thead>
<tr>
<th>Input Variable</th>
<th>USEANSISQLQUOTES</th>
<th>NOUSEANSISQLQUOTES</th>
</tr>
</thead>
<tbody>
<tr>
<td>Literal text is: John’s Car</td>
<td>'John''s' car</td>
<td>&quot;John's car&quot;</td>
</tr>
<tr>
<td>This example uses two apostrophes, one as the literal apostrophe and the other as the escape character. (The apostrophe is the same character as the single quote mark.)</td>
<td>No escape character is needed.</td>
<td></td>
</tr>
<tr>
<td>Literal text is: Double quote (&quot;)</td>
<td>'Double quote (&quot;)'</td>
<td>&quot;Double quote (&quot;)&quot;</td>
</tr>
<tr>
<td>No escape character is needed.</td>
<td>This example uses two double quotes, one as the literal double quote and the other as the escape character.</td>
<td></td>
</tr>
<tr>
<td>Column name is: &quot;Column&quot;1</td>
<td>&quot;Column&quot;1&quot;</td>
<td>Not supported.</td>
</tr>
<tr>
<td>This example uses two double quotes, one as the literal double quote and the other as the escape character.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
USEDEDICATEDCOORDINATIONTHREAD

Valid For

Replicat (coordinated mode)

Description

Use USEDEDICATEDCOORDINATIONTHREAD to force Replicat to maintain a dedicated coordination thread to apply barrier transactions. The thread ID of this thread is always 0.

By default, Replicat uses the thread with the lowest thread ID to apply barrier transactions, but that thread also includes work that is mapped to it explicitly. By using a dedicated thread for barrier transactions, you can get an accurate view in Oracle GoldenGate statistics of the number of barrier events and exposes the amount of work that is performed serially. Coordinated Replicat statistics are written to the report file and also can be viewed with the STATS REPLICAT command.

USEDEDICATEDCOORDINATIONTHREAD applies to the Replicat group as a whole, across all MAP statements.

Syntax

USEDEDICATEDCOORDINATIONTHREAD

Example

USEDEDICATEDCOORDINATIONTHREAD
MAP u1.t1, TARGET u2.t1 SQLEXEC &
(ID test2, QUERY 'delete from u2.t2 where col_val =100 ', &
NOPARAMS)), THREAD(1), COORDINATED;
USEIPV4

Valid For

GLOBAL

Description

Use the USEIPV4 parameter to force the use of Internet Protocol version 4 (IPv4) by Oracle GoldenGate for TCP/IP connections. By default, Oracle GoldenGate uses IPv6 in dual-stack mode and this parameter forces the use of IPv4 only.

When USEIPV4 is used, the entire network in which Oracle GoldenGate operates must be IPv4 compatible.

Default

Disabled

Syntax

USEIPV4
USEIPV6

Valid For

GLOBALs

Description

Use the USEIPV6 parameter to force the use of Internet Protocol version 6 (IPv6) by Oracle GoldenGate for TCP/IP connections. By default, Oracle GoldenGate uses IPv6 in dual-stack mode but falls back to IPv4, and only then to IPv6. USEIPV6 eliminates the IPv4 fallback step. The order of socket selection becomes:

- IPv6 dual-stack
- IPv6

When USEIPV6 is used, the entire network in which Oracle GoldenGate operates must be IPv6 compatible.

Default

Disabled

Syntax

USEIPV6
USERID

Valid For
Manager, Extract, Replicat, DEFGEN

Supported for
DB2 for i
DB2 LUW
DB2 on z/OS
Oracle
MySQL
SQL/MX
SQL Server
Sybase
Teradata
TimesTen

Description
Use the USERID parameter to specify the type of authentication for an Oracle GoldenGate process to use when logging into a database, and to specify password encryption information. This parameter can be used instead of USERIDALIAS when an Oracle GoldenGate credential store is not being used.

Always use USERID or USERIDALIAS for a primary Extract and for Replicat. Use USERID or USERIDALIAS for a data pump Extract unless it is configured in PASSTHRU mode.
Always use USERID or USERIDALIAS for Replicat. Use USERID or USERIDALIAS for Manager only if using parameters that require Manager to log into the source or target database.

USERID Compared to USERIDALIAS
USERID requires either specifying the clear-text password in the parameter file or encrypting it with the ENCRYPT PASSWORD command and, optionally, storing an encryption key in an ENCKEYS file. USERID supports a broad range of the databases that Oracle GoldenGate supports.

USERIDALIAS enables you to specify an alias, rather than a user ID and password, in the parameter file. The user IDs and encrypted passwords are stored in a credential store. USERIDALIAS supports databases running on Linux, UNIX, and Windows platforms.

See Administering Oracle GoldenGate for Windows and UNIX for more information about Oracle GoldenGate security features.

General Requirements for USERID
Specify USERID before any TABLE or MAP entries in an Extract or Replicat parameter file. Specify USERID in a Manager parameter file if Manager must access the database and a login is required.
**USERID Requirements per Database Type**

The usage of **USERID** varies depending on the database type.

**DB2 for i**

Use **USERID** with **PASSWORD** to specify the name and password of the user profile assigned to the Oracle GoldenGate process. Use **SOURCEDB** or **TARGETDB** with **USERID** to specify the default DB2 for i database that is identified by the system name (in upper case). See *Installing and Configuring Oracle GoldenGate for DB2 for i* for more information.

**DB2 for LUW**

Use **USERID** with **PASSWORD** and preceded by **SOURCEDB** or **TARGETDB** for all Oracle GoldenGate processes that connect to a DB2 LUW database using database authentication. You can omit **USERID** and **PASSWORD** (and only use **SOURCEDB** or **TARGETDB**) if the database is configured allow authentication at the operating-system level.

**DB2 for z/OS database**

Use **USERID** with **PASSWORD** if the user that is assigned to the Oracle GoldenGate process does not have the DB2 privileges that are required for the process to function properly.

**MySQL**

Use **USERID** with **PASSWORD** for all Oracle GoldenGate processes that connect to a MySQL database.

**Oracle**

Use **USERID** for Oracle GoldenGate processes that connect to an Oracle database.

- To use an operating system login, use **USERID** with the / argument.
- To use a database user name and password, use **USERID** with **PASSWORD**.
- Optionally, you can specify the user to log in as sysdba.
- *(Oracle Enterprise Edition earlier than 11.2.0.2)* Special database privileges are required for the **USERID** user when Extract is configured to use **LOGRETENTION**. These privileges might have been granted when Oracle GoldenGate was installed. See the *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about **LOGRETENTION**.

---

**Note:** The privileges that are required for the **USERID** user vary by database. See the appropriate Oracle GoldenGate installation guide for your database to determine the privileges that are required for the Oracle GoldenGate database users.
Oracle GoldenGate Parameters

■ (Oracle Standard or Enterprise Edition 11.2.0.2 or later) To use USERID for an Extract group that is configured for integrated capture, the user must have the privileges granted in the dbms_goldengate_auth.grant_admin_privilege procedure, and the user must be the same one that issues DBLOGIN and REGISTER EXTRACT or UNREGISTER EXTRACT for the Extract group that is associated with this USERID.

■ To support capture from an Oracle container database, the user that is specified with USERID must log into the root container and must be a common user. A connect string must be supplied for this user and must include the required C## prefix of the common user, such as C##GGADMIN@FINANCE. For more information, see Installing and Configuring Oracle GoldenGate for Oracle Database.

SQL/MX

■ For Oracle GoldenGate processes that connect to a source SQL/MX database, use the SOURCEDB or TARGETDB parameter to specify the catalog name, and in the same parameter statement use USERID without PASSWORD to specify the default schema.

■ For Oracle GoldenGate processes that connect to a target SQL/MX database, use the TARGETDB parameter to specify the target ODBC data source, and in the same parameter statement use USERID with PASSWORD. Replicat uses ODBC/MX to connect to the SQL/MX database.

SQL Server

Use USERID with PASSWORD if the ODBC data source connection that will be used by the Oracle GoldenGate process is configured to supply database authentication. USERID can be a specific login that is assigned to the process or any member of an account in the System Administrators or Server Administrators fixed server role.

■ On a source SQL Server system, also use the SOURCEDB parameter to specify the source ODBC data source.

■ On a target SQL Server system, also use the TARGETDB parameter to specify the target ODBC data source.

Sybase

Use USERID and PASSWORD for Oracle GoldenGate processes that connect to a Sybase database.

Teradata

Use USERID with PASSWORD for Oracle GoldenGate processes that connect to a Teradata database.

■ On a source Teradata system, also use the SOURCEDB parameter to specify the source ODBC data source.

■ On a target Teradata system, also use the TARGETDB parameter to specify the target ODBC data source.

TimesTen

Use USERID with PASSWORD if the ODBC data source connection that will be used by Replicat is configured to supply database authentication. Also use the TARGETDB parameter to specify the target ODBC data source.

Default

None
Syntax

```
USERID {/ | user}[, PASSWORD password]
[algorithm ENCRYPTKEY {key_name | DEFAULT}] [SYSDBA]
[, THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])]
```

/ (Oracle) Directs Oracle GoldenGate to use an operating-system login for Oracle, not a
database user login. Use this argument only if the database allows authentication at
the operating-system level. Bypassing database-level authentication eliminates the
need to update Oracle GoldenGate parameter files if application passwords frequently
change. To use this option, the correct user name must exist in the database, in relation
to the value of the Oracle OS_AUTHENT_PREFIX initialization parameter, as follows:

- The value set with OS_AUTHENT_PREFIX is concatenated to the beginning of a user's
  operating-system account name and then compared to the database name. Those
two names must match.
- If OS_AUTHENT_PREFIX is set to ' ' (a null string), the user name must be created
  with IDENTIFIED EXTERNALLY. For example, if the OS user name is ogg, you would
  use the following to create the database user:

  ```
  CREATE USER ogg IDENTIFIED EXTERNALLY;
  ```

- If OS_AUTHENT_PREFIX is set to OPS$ or another string, the user name must be
  created in the following format:

  ```
  OS_AUTHENT_PREFIX_value OS_user_name
  ```

  For example, if the OS user name is ogg, you would use the following to create the
  database user:

  ```
  CREATE USER ops$ogg IDENTIFIED BY oggpassword;
  ```

**user**

Specifies the name of a database user or a schema, depending on the database
configuration. For Oracle, a SQL*Net connect string can be used. Refer to Section 3,
"USERID Requirements per Database Type" for additional guidelines.

**password**

Use when database authentication is required to specify the password for the database
user. If the password was encrypted by means of the ENCRYPT PASSWORD command,
supply the encrypted password; otherwise, use the clear-text password. If the
password is case-sensitive, type it that way.

If either the user ID or password changes, the change must be made in the Oracle
GoldenGate parameter files, including the re-encryption of the password if necessary.

**algorithm**

Specifies the encryption algorithm that was used to encrypt the password with
ENCRYPT PASSWORD. Password encryption is not supported for SQL/MX.

The algorithm can be one of:

- AES128
- AES192
- AES256
- BLOWFISH
ENCRYPTKEY (key_name | DEFAULT)
Specifies the encryption key that was specified with ENCRYPT PASSWORD.

- ENCRYPTKEY key_name specifies the logical name of a user-created encryption key in the ENCKEYS lookup file. Use if ENCRYPT PASSWORD was used with the KEYNAME key_name option.
- ENCRYPTKEY DEFAULT directs Oracle GoldenGate to use a random key. Use if ENCRYPT PASSWORD was used with the KEYNAME DEFAULT option.

SYSDBA
(Oracle) Specifies that the user logs in as sysdba.

THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])
Valid for Replicat. Links the specified credential to one or more threads of a coordinated Replicat. Enables you to specify different logins for different threads.

threadID[, threadID][, ...]
Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

[, thread_range[, thread_range][, ...]]
Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID, threadIDlow-threadIDhigh.

Examples

Example 1
USERID /

Example 2
USERID ogg

Example 3
USERID ogg@ora1.ora, &
PASSWORD AACAAAAAAAAAAAAAAAAJAUEUGODSCVGJEEIIUGKJDJTPNDKEJFFFTC AES128, &
ENCRYPTKEY securekey1

Example 4
USERID ogg, PASSWORD AACAAAAAAAAAAAAAAAAJAUEUGODSCVGJEEIIUGKJDJTPNDKEJFFFTC &
AES128, ENCRYPTKEY securekey1

Example 5
USERID ogg, PASSWORD AACAAAAAAAAAAAAAAAAJAUEUGODSCVGJEEIIUGKJDJTPNDKEJFFFTC &
BLOWFISH, ENCRYPTKEY DEFAULT

Example 6
USERID ogg, &
PASSWORD AACAAAAAAAAAAAAAAAAJAUEUGODSCVGJEEIIUGKJDJTPNDKEJFFFTC AES128, &
ENCRYPTKEY securekey1 SYSDBA
USERIDALIAS

Valid For
Manager, Extract, Replicat, DEFGEN

Supported for
DB2 for i
DB2 LUW
DB2 on z/OS
Oracle
MySQL
SQL/MX
SQL Server
Sybase
Teradata
TimesTen

Description
Use the USERIDALIAS parameter to specify authentication for an Oracle GoldenGate process to use when logging into a database. The use of USERIDALIAS requires the use of an Oracle GoldenGate credential store. Specify USERIDALIAS before any TABLE or MAP entries in the parameter file.

Note: The privileges that are required for the USERIDALIAS user vary by database. See the appropriate Oracle GoldenGate installation guide for your database to determine the privileges that are required for the Oracle GoldenGate database users.

USERIDALIAS Compared to USERID
USERIDALIAS enables you to specify an alias, rather than a user ID and password, in the parameter file. The user IDs and encrypted passwords are stored in a credential store. USERIDALIAS supports databases running on Linux, UNIX, and Windows platforms.

USERID requires either specifying the clear-text password in the parameter file or encrypting it with the ENCRYPT PASSWORD command and, optionally, storing an encryption key in an ENCKEYS file. USERID supports a broad range of the databases that Oracle GoldenGate supports. In addition, it supports the use of an operating system login for Oracle databases.

See Administering Oracle GoldenGate for Windows and UNIX for more information about these parameters and Oracle GoldenGate security features.

USERIDALIAS Requirements per Database Type
The usage of USERIDALIAS varies depending on the database type.
USERIDALIAS

**Note:** Logins that require a database user and password must be stored in the Oracle GoldenGate credential store. See *Administering Oracle GoldenGate for Windows and UNIX* for more information about the credential store.

---

**DB2 for LUW**

Use `USERIDALIAS` with the `SOURCEDB` or `TARGETDB` parameter for all Oracle GoldenGate processes that connect to a DB2 LUW database using database authentication. You can omit `USERIDALIAS` and only use `SOURCEDB` or `TARGETDB` if the database is configured to allow authentication at the operating-system level. See "SOURCEDB" on page 3-280 and "TARGETDB" on page 3-350 for more information.

**MySQL**

Use `USERIDALIAS` for all Oracle GoldenGate processes that connect to a MySQL database. The `SOURCEDB` or `TARGETDB` parameter is not required.

**Oracle**

Use `USERIDALIAS` for Oracle GoldenGate processes that connect to an Oracle database.

- The `SOURCEDB` or `TARGETDB` parameter is not required.
- Specify the alias of a database credential that is stored in the Oracle GoldenGate credential store.
- *(Oracle Enterprise Edition earlier than 11.2.0.2)* Special database privileges are required for the `USERIDALIAS` user when Extract is configured to use `LOGRETENTION`. These privileges might have been granted when Oracle GoldenGate was installed. See the *Installing and Configuring Oracle GoldenGate for Oracle Database* for more information about `LOGRETENTION`.
- *(Oracle Standard or Enterprise Edition 11.2.0.2 or later)* To use `USERIDALIAS` for an Extract group that is configured for integrated capture, the user must have the privileges granted in the `dbms_goldengate_auth.grant_admin_privilege` procedure, and the user must be the same one that issues `DBLOGIN` and `REGISTER EXTRACT` or `UNREGISTER EXTRACT` for the Extract group that is associated with this `USERIDALIAS`.
- To support capture from an Oracle container database, the user that is specified with `USERID` must log on to the root container and must be a common database user. A connect string must be supplied for this user, for example: `C##GGADM@FINANCE`. For more information, see *Installing and Configuring Oracle GoldenGate for Oracle Database*.

**SQL Server**

Use `USERIDALIAS` if the ODBC data source connection that will be used by the Oracle GoldenGate process is configured to supply database authentication. `USERIDALIAS` can be a specific login that is assigned to the process or any member of an account in the `System Administrators` or `Server Administrators` fixed server role.

- On a source SQL Server system, also use the `SOURCEDB` parameter to specify the source ODBC data source.
- On a target SQL Server system, also use the `TARGETDB` parameter to specify the target ODBC data source.
**Sybase**

Use `USERIDALIAS` for Oracle GoldenGate processes that connect to a Sybase database.

**Teradata**

Use `USERIDALIAS` for Oracle GoldenGate processes that connect to a Teradata database.

- On a source Teradata system, also use the `SOURCEDB` parameter to specify the source ODBC data source.
- On a target Teradata system, also use the `TARGETDB` parameter to specify the target ODBC data source.

**TimesTen**

Use `USERIDALIAS` if the ODBC data source connection that will be used by Replicat is configured to supply database authentication. Also use the `TARGETDB` parameter to specify the target ODBC data source.

**Default**

None

**Syntax**

```
USERIDALIAS alias [DOMAIN domain] [SYSDBA]
[,] THREADS (threadID[, threadID][, ...][, thread_range[, thread_range][, ...]])
```

- **alias**: Specifies the alias of a database user credential that is stored in the Oracle GoldenGate credential store. Refer to Section 3, "USERID Requirements per Database Type" for additional guidelines.

- **DOMAIN domain**: Specifies the credential store domain for the specified alias. A valid domain entry must exist in the credential store for the specified alias.

- **SYSDBA**: (Oracle) Specifies that the user logs in as sysdba.

- **THREADS**: `threadID[, threadID][, ...][, thread_range[, thread_range][, ...]]`

  Valid for Replicat. Links the specified credential to one or more threads of a coordinated Replicat. Enables you to specify different logins for different threads.

  - **threadID[, threadID][, ...]**
    Specifies a thread ID or a comma-delimited list of threads in the format of threadID, threadID, threadID.

  - **[, thread_range[, thread_range][, ...]**
    Specifies a range of threads in the form of threadIDlow-threadIDhigh or a comma-delimited list of ranges in the format of threadIDlow-threadIDhigh, threadIDlow-threadIDhigh.

A combination of these formats is permitted, such as threadID, threadID,
threadIDlow-threadIDhigh.
Examples

Example 1
The following supplies a credential for the user in the credential store that has the alias of tiger1 in the domain of east.

Example 2
The following supplies a credential for thread 3 of a coordinated Replicat.

USERIDALIAS tiger1 DOMAIN east THREADS (3)
**VAM**

**Valid For**

Extract

**Description**

Use the VAM parameter to specify that a Vendor Access Module (VAM) is being used to perform data capture functions for the Extract process and send it to the Extract API. This parameter supplies required input for the VAM API.

**Default**

None

**Syntax**

```
VAM library, PARAMS ('param' [, 'param'] [, ...])
```

library

The name of the library that is supplied by the database vendor as a Windows DLL or a UNIX shared object. Use the full path name if the library is in a directory other than the Oracle GoldenGate directory.

**Note:** Teradata calls this library the Teradata Access Module (TAM). This program or library communicates with the Oracle GoldenGate VAM API.

**PARAMS 'param'**

Any parameter, enclosed within single quotes, that is passed to the Oracle GoldenGate API. See the following database-specific parameter options.

**ARLIBError error, action**

Valid for SQL/MX.

Specifies how TMFARLIB errors are handled by the VAM.

- **error** is an ARLIB error number.
- **action** can be ABEND | WARN | IGNORE.

The default is ABEND. Errors -1000 and -2000 will always result in ABEND, regardless of any other action that is specified.

Examples:

```plaintext
Vam Params (arliberror (-16,-14), Warn)
Vam Params (arliberror -2000, Abend)
Vam Params (arliberror -1000, Abend)
```

**ARErrorReportInterval seconds**

Valid for SQL/MX.

Sets the interval, in seconds, in which the same TMFARLIB error is reported back to Extract. This reduces the amount of messages for each type of error that accumulate. seconds must be greater than, or equal to, zero. The default is 60 seconds.
inifile, ini_file, callbackLib, extract.exe
Required parameter for Teradata.

- **inifile** indicates that the next parameter specifies the TAM initialization file.
- **ini_file** is the name of the TAM initialization file. Unless the file resides in the same directory where the Extract program is installed, specify the fully qualified path name.
- **callbackLib** indicates that the next parameter specifies the program that interfaces with the TAM. This parameter is case-sensitive and must be entered exactly as shown here.
- **extract.exe** is the Extract program, which is the callback program for the TAM.

**CDCRECORDSFETCHCOUNT, CDCSESSIONTIMEOUT, CDCRECORDQUEUESIZE**
Valid for Informix.

- **CDCRECORDSFETCHCOUNT** specifies the number of CDC records to be fetched in one call. For example, the CDC record batch size. The default number of records is 10. When there are not 10 records to fetch from transaction log the CDC API fetches old records, which causes duplication that may lead to either an Extract or Replicat abend. Also, it is possible that the Extract statistics may show incorrect output. To avoid this condition, use `VAM PARAMS (CDCRECORDSFETCHCOUNT 1)` in the Extract parameter file.
- **CDCSESSIONTIMEOUT** specifies the CDC session timeout in seconds. The default is 2 seconds.
- **CDCRECORDQUEUESIZE** specifies the queue size used to store the transaction log records. The default is 256 records.

**LOGICALLOGWARNINGTHRESHOLD**
Valid for Informix.

The input is the usage threshold given by percentage (%) of the current logical log file used by the Informix Dynamic Server. The default value is 50, so 50%. If Oracle GoldenGate capture is positioned at the oldest logical log file and the current logical log file usage exceeds this specified threshold, then a warning message is written to the report file.

### Examples

```
VAM tam.dll, PARAMS (inifile, tam.ini, callbackLib, extract.exe)
VAM PARAMS (CDCRECORDSFETCHCOUNT 5)
VAM PARAMS (CDCRECORDSFETCHCOUNT 5 CDCSESSIONTIMEOUT 5)
VAM PARAMS (CDCRECORDQUEUESIZE 512)
VAM PARAMS (LOGICALLOGWARNINGTHRESHOLD 65)
```
VARWIDTHNCHAR | NOVARWIDTHNCHAR

Valid For

Extract, Replicat, DEFGEN for Oracle

Description

Use the VARWIDTHNCHAR and NOVARWIDTHNCHAR parameters to control how NCHAR data is written to the trail and interpreted by Replicat.

- VARWIDTHNCHAR causes an NCHAR, NVARCHAR2, or NCLOB character set to be treated as a variable-length character set (UTF-8).
- NOVARWIDTHNCHAR causes an NCHAR, NVARCHAR2, or NCLOB character set to be treated as UTF-16.
- If neither option is specified, the NLS_NCHAR_CHARACTERSET property value from the database is used to determine how an NCHAR, NVARCHAR2, or NCLOB character set is treated.

Default

Use NLS_NCHAR_CHARACTERSET property from database

Syntax

VARWIDTHNCHAR | NOVARWIDTHNCHAR
WALLETLOCATION

Valid For

GLOBAL

Description

Use the WALLETLOCATION parameter to specify the location of the Oracle GoldenGate master-key wallet.

Default

`dirwl` subdirectory of the Oracle GoldenGate installation directory

Syntax

```
WALLETLOCATION directory_path
```

- `directory_path`
  Specifies the full path name of the wallet location.

Example

```
WALLETLOCATION /home/ggadmin/walletdir
```
WARNLONGTRANS

Valid For

Extract

Description

Use the WARNLONGTRANS parameter to specify a length of time that a transaction can be open before Extract generates a warning message that the transaction is long-running. Also use WARNLONGTRANS to control the frequency with which Oracle GoldenGate checks for long-running transactions.

This parameter is valid for Oracle, SQL/MX, SQL Server, and Sybase.

When WARNLONGTRANS is specified, Oracle GoldenGate checks for transactions that satisfy the specified threshold, and it reports the first one that it finds to the Oracle GoldenGate error log, the Extract report file, and the system log. By default, Oracle GoldenGate repeats this check every five minutes.

To view a list of open transactions on demand, to output transaction details to a file, or to either cancel those transactions or force them to the trail, use the options of the SEND EXTRACT command. See "SEND EXTRACT" on page 1-37 for more information.

Default

One hour (and check every five minutes using a separate processing thread)

Syntax

WARNLONGTRANS duration
[, CHECKINTERVAL interval]
[, NOUSETHREADS]
[, USELASTREADTIME]

duration

Sets a length of time after which an open transaction is considered to be long-running. The duration is specified as a whole number, followed by the unit of time in any of the following formats to indicate seconds, minutes, or hours. Do not put a space between the numeric value and the unit of time. The unit is not case-sensitive. The default is one hour.

S|SEC|SECS|SECOND|SECONDS
M|MIN|MINS|MINUTE|MINUTES
H|HOUR|HOURS
D|DAY|DAYS

The following are examples of valid durations:

WARNLONGTRANS 2HRS
WARNLONGTRANS 2hours
WARNLONGTRANS 1DAY
WARNLONGTRANS 600sec
WARNLONGTRANS 40s

CHECKINTERVAL interval

Sets the frequency at which Oracle GoldenGate checks for transactions that satisfy WARNLONGTRANS and reports the longest running one. The interval is specified as a whole number, followed by the unit of time in any of the following formats to indicate
seconds, minutes, or hours. Do not put a space between the numeric value and the unit of time. The unit is not case-sensitive. The default is five minutes, which is also the minimum valid value.

S | SEC | SECS | SECOND | SECONDS
M | MIN | MINS | MINUTE | MINUTES
H | HOUR | HOURS
D | DAY | DAYS

The following are examples of valid interval specifications:

CHECKINTERVAL 2hrs
CHECKINTERVAL 2HOURS
CHECKINTERVAL 1day
CHECKINTERVAL 600SEC
CHECKINTERVAL 2m

NOUSETHREADS
Valid for Oracle.

Specifies that the monitoring will be done by the main process thread. By default, it is done with a separate thread for performance reasons. NOUSETHREADS should only be used if the system does not support multi-threading.

USELASTREADTIME
Valid for Oracle.

Forces Extract to always use the time that it last read the Oracle redo log to determine whether a transaction is long-running or not. By default, Extract uses the timestamp of the last record that it read from the redo log. This applies to an Extract that is running in archive log only mode, as configured with TRANLOGOPTIONS using the ARCHIVEDLOGONLY option.

Example

WARNLONGTRANS 2h, CHECKINTERVAL 3m, NOUSETHREADS
WARNRATE

Valid For

Replicat

Description

Use the `WARNRATE` parameter to set a threshold for the number of SQL errors that can be tolerated on any target table before being reported to the process report and to the error log. The errors are reported as a warning. If your environment can tolerate a large number of these errors, increasing `WARNRATE` helps to minimize the size of those files.

When setting `WARNRATE` for a coordinated Replicat, take into account that the specified `WARNRATE` threshold is applied to each thread in the configuration, not as an aggregate threshold for Replicat as a whole. For example, if `WARNRATE 100` is specified, it is possible for each thread to return 99 errors without a warning from Replicat.

For Replicat running in an Oracle environment, this parameter is valid for nonintegrated mode only.

Default

100 errors

Syntax

```
WARNRATE number_of_errors
```

`number_of_errors`

The number of SQL errors after which a warning is issued.

Example

```
WARNRATE 1000
```
WILDCARDRESOLVE

Valid For

Extract and Replicat

Description

Use the WILDCARDRESOLVE parameter to alter the rules for processing wildcarded table specifications in a TABLE, SEQUENCE, or MAP statement. WILDCARDRESOLVE must precede the associated TABLE, SEQUENCE, or MAP statements in the parameter file.

The target objects must already exist in the target database when wildcard resolution is attempted. If a target object does not exist, Replicat abends.

Default

DYNAMIC

Syntax

WILDCARDRESOLVE (DYNAMIC | IMMEDIATE)

DYNAMIC

Source objects that satisfy the wildcard definition are resolved each time the wildcard rule is satisfied. The newly resolved object is included in the Oracle GoldenGate configuration upon resolution. This is the default. This is the required setting for Teradata.

Do not use this option when SOURCEISTABLE or GENLOADFILES is specified. WILDCARDRESOLVE will always be implicitly set to IMMEDIATE for these parameters.

DYNAMIC must be used when using wildcards to replicate Oracle sequences with the SEQUENCE parameter.

To keep the default of DYNAMIC, an explicit WILDCARDRESOLVE parameter is optional, but its presence helps make it clear to someone who is reviewing the parameter file which method is being used.

IMMEDIATE

Source objects that satisfy the wildcard definition are processed at startup. This option is not supported for Teradata. This is the forced default for SOURCEISTABLE.

This option does not support the Oracle interval partitioning feature. Dynamic resolution is required so that new partitions are found by Oracle GoldenGate.

Example

The following example resolves wildcards at startup.

WILDCARDRESOLVE IMMEDIATE
TABLE hq.acct_*;
Y2KCENTURYADJUSTMENT | NOY2KCENTURYADJUSTMENT

Valid For

Replicat

Description

Use the Y2KCENTURYADJUSTMENT and NOY2KCENTURYADJUSTMENT parameters to control the conversion of year values when the century portion consists of zeroes (such as 0055) or is not specified (such as in a two-digit, year-only specification).

With Y2KCENTURYADJUSTMENT enabled (the default), a two-digit year value that is greater than or equal to 50 is converted to a four-digit year in the 20th century (19xx). If a two-digit year value is less than 50, it is converted to a four-digit year in the 21st century (20xx).

If the century portion of the year is non-zero, or if NOY2KCENTURYADJUSTMENT is specified, no conversion is performed.

Default

Y2KCENTURYADJUSTMENT

Syntax

Y2KCENTURYADJUSTMENT | NOY2KCENTURYADJUSTMENT
This chapter describes the parameters for the Collector process and includes the following topics:

- "Overview of the Collector Process"
- “Summary of Collector Parameters”

The Collector process operates on the target system to receive incoming data and write it to the trail. For more information about Collector, see Administering Oracle GoldenGate for Windows and UNIX.

4.1 Overview of the Collector Process

Typically, Oracle GoldenGate users do not interact with the Collector process. This is known as a dynamic collector. It is started dynamically by the Manager process, but parameters may be sent to Collector as options of certain Extract or Replicat parameters.

As an alternative to allowing Manager to run Collector, you can run a static Collector manually by running the SERVER program at the command line with the following syntax and input parameters as shown:

```
server parameter [parameter] [...]
```

Collector parameters are case-sensitive and must be preceded by a dash. For example, `-e` and `-E` are two different parameters, with entirely different results.

4.2 Summary of Collector Parameters

The following is a summary of available Collector parameters.

<table>
<thead>
<tr>
<th>Table 4–1 Collector Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>----------</td>
</tr>
<tr>
<td><code>-b</code></td>
</tr>
<tr>
<td><code>-cp</code></td>
</tr>
<tr>
<td><code>-d</code></td>
</tr>
<tr>
<td><code>-E</code></td>
</tr>
<tr>
<td><code>-e</code></td>
</tr>
</tbody>
</table>
### Table 4-1 (Cont.) Collector Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-ENCRYPT</code></td>
<td>Specifies the type of encryption being passed from the Extract process, as specified with the <code>RMTHOST</code> parameter in the Extract parameter file.</td>
</tr>
<tr>
<td><code>-f</code></td>
<td>Forces all file writes to be flushed to disk before returning a success status to the Extract process.</td>
</tr>
<tr>
<td><code>-g</code></td>
<td>Supports files that are larger than 2GB (Solaris only).</td>
</tr>
<tr>
<td><code>-h</code></td>
<td>Specifies the name or IP address of the source system.</td>
</tr>
<tr>
<td><code>-k</code></td>
<td>Directs Collector to terminate when the Extract process that it is serving disconnects.</td>
</tr>
<tr>
<td><code>-KEYNAME</code></td>
<td>Specifies the name of a key that is defined in the local <code>ENCKEYS</code> lookup file.</td>
</tr>
<tr>
<td><code>-l</code></td>
<td>Logs output to the specified file.</td>
</tr>
<tr>
<td><code>-m</code></td>
<td>Specifies the maximum number of log files to allocate.</td>
</tr>
<tr>
<td><code>-P</code></td>
<td>Specifies a local file that contains Collector parameters.</td>
</tr>
<tr>
<td><code>-p</code></td>
<td>Specifies a TCP/IP port number.</td>
</tr>
<tr>
<td><code>-R</code></td>
<td>Replaces invalid numeric ASCII data with an alternate value.</td>
</tr>
<tr>
<td><code>-x</code></td>
<td>Specifies a discard file to store records that could not be processed by Oracle GoldenGate.</td>
</tr>
</tbody>
</table>
Specifies the default file buffer size.

Syntax:
-B size

If size is not specified, then the default size is your C library default file buffer size (BUFSIZ). The minimum value is 16 KB and the maximum is 16 MB; zero (0) indicates unbuffered.
-cp

Specifies the name of the checkpoint file that Collector maintains for an alias Extract group. The checkpoint file is used to determine whether the passive Extract is running or not. It is running when the checkpoint file is locked by Collector (shown as the server program in the Oracle GoldenGate installation directory).

-cp must be used with the -h and -p parameters.

For more information about using passive and alias Extract groups, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

- cp checkpoint_file

 **cp**

Must be lower case.

 **checkpoint_file**

The name of the file to which the passive Extract group writes its checkpoints. The name of the passive Extract group and the name of the checkpoint file are identical.
-d

Specifies the name of a local definitions file that was generated by the DEFGEN utility. The file contains the definitions of tables that reside on a remote system. For more information about definitions files, see Administering Oracle GoldenGate for Windows and UNIX.

**Syntax**

- **-d** definitions_file

  Must be lower case.

  **definitions_file**
  The name of the definitions file, exactly as specified when DEFGEN was run.
Converts incoming header and data to EBCDIC format from ASCII. By default, Oracle GoldenGate does not convert the data.

**Syntax**

```
-E
```

Must be upper case.
Directs Collector to respond to specific formatting error conditions in custom ways. Default values are almost always sufficient. To specify more than one error type, use -e multiple times. For example:

- e OLD CONTINUE -e NEW DISCARD.

**Syntax**

- e type action

  e
  Must be lower case.

  **type**
  Specifies the type of error that generates the response and can be one of the following:

  **NEW**
  Checks for records that contain more data than anticipated (more columns than the current definition). The Collector process may need an updated version of the source table (that is, DEFGEN must be run again). The default action is ABEND.

  **OLD**
  Checks for records that contain less data than anticipated. This usually indicates that a record has fewer columns than the table’s current definition, which is considered a normal condition. The default action is CONTINUE.

  **OUTOFSYNC**
  Checks for records that cannot be converted according to the definition provided. The default action is ABEND.

  **action**
  Specifies the response to the error and can be one of the following:

  **ABEND**
  Discards the record and directs the Extract process to end immediately.

  **CONTINUE**
  Processes the record (if possible) regardless of the conversion error encountered.

  **DISCARD**
  Outputs the record to a discard file (if one is specified with -x). Collector sends a warning to the error file for the first discarded record and continues to process records.
Specifies the type of encryption being passed from the Extract process, as specified with the RMTHOST parameter in the Extract parameter file. For more information about Oracle GoldenGate security, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

-ENCRYPT {NONE | BLOWFISH}

**ENCRYPT**
Must be upper case.

**NONE**
Specifies that the data will not be encrypted.

**BLOWFISH**
Specifies BLOWFISH encryption. If using BLOWFISH, also specify the -KEYNAME option.
-f

Forces all file writes to be flushed to disk before returning a success status to the Extract process. By default, the file system buffers the I/O because it is more efficient than flushing to disk with every operation. Generally, the performance benefits outweigh the small risk that data could be lost if the system fails after an I/O is confirmed successful, but before the buffer actually is flushed to disk. Use -f if this risk is unacceptable, with the understanding that it can compromise the performance of Oracle GoldenGate

Syntax

-f

f
Must be lower case.
-g

Supports files that are larger than 2GB (Solaris only).

Syntax

```
-g

-g

Must be lower case.
```
-h

Specifies the name or IP address of the source system. Use this option when using an alias Extract on the target that is associated with an Extract running in PASSIVE mode on the source. It causes Collector to operate in connection mode. In this mode, it initiates a TCP/IP connection to the source Extract, instead of waiting for a connection request from Extract. Must be used with the -p Collector option. For more information about PASSIVE mode and Oracle GoldenGate security, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

```
-h (host_name | IP_address)
```

h
Must be lower case.

**host_name**
Specifies the source system by its DNS host name.

**IP_address**
Specifies the source system by its IP address.
Directs Collector to terminate when the Extract process that it is serving disconnects. This option is used by the Manager process when starting the Collector process.

**Syntax**

```text
-k

k
Must be lower case.
```
-KEYNAME

Specifies the name of a key that is defined in the local ENCKEYS lookup file. Use if BLOWFISH is specified for -ENCRYPT. For more information about the ENCKEYS file and Oracle GoldenGate security, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

-KEYNAME  key_name

KEYNAME
Must be upper case.

key_name
The name of the key as it appears in the ENCKEYS file.
Logs output to the specified file.

**Syntax**

```plaintext
-l file_name
```

<table>
<thead>
<tr>
<th></th>
<th>Must be lower case.</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>file_name</code></td>
<td>The fully qualified name of the output file.</td>
</tr>
</tbody>
</table>
-m

Specifies the maximum number of log files to allocate.

Syntax

- m number

m
Must be lower case.

number
The maximum number of files to allocate.
-P

Specifies a local file that contains Collector parameters. Parameters in this file override parameters sent from the Extract process.

Syntax

-P file_name

P
Must be upper case.

file_name
The fully qualified name of the parameter file.
-p

Specifies a TCP/IP port number as follows:

- For a regular Extract or regular data pump: the port on which the Collector process listens for connection requests from Extract.
- For an Extract or data pump running in PASSIVE mode: the port on which Extract or the data pump listens for connection requests from Collector. Must be used with the -h host parameter in this case. For more information about PASSIVE mode and Oracle GoldenGate security, see Administering Oracle GoldenGate for Windows and UNIX.

**Syntax**

- `p` `port`

  **p**
  Must be lower case.

  **port**
  The port number. The default is port 7819.
**-R**

Replaces invalid numeric ASCII data with an alternate value.

**Syntax**

```
-R value
```

**R**

Must be upper case.

**value**

The replacement value. The default is to replace with 0. Specify one of the following alternate values:

- **number**
  Replaces invalid data with the specified number.

- **NULL**
  Replaces invalid data with **NULL** if the target column accepts **NULL** values. Otherwise, replaces with 0.

- **UNPRINTABLE**
  Rejects any column with unprintable data. The process stops and reports the bad value.

- **NONE**
  Does not replace numeric data. Oracle GoldenGate attempts to replicate the data as-is.
Specifies a discard file to store records that could not be processed by Oracle GoldenGate.

**Syntax**

```
-x discard_file
```

-x

Must be lower case.

*discard_file*

The fully qualified name of the discard file.
The column conversion functions of Oracle GoldenGate enable you to manipulate source values into the appropriate format for target columns. You can manipulate numbers and characters, perform tests, extract parameter values, return environment information, and more. For more information about using these functions, see Administering Oracle GoldenGate for Windows and UNIX.

5.1 Summary of Column-Conversion Functions

This summary is organized according to the types of processing that can be performed with the Oracle GoldenGate functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CASE</td>
<td>Selects a value depending on a series of value tests.</td>
</tr>
<tr>
<td>EVAL</td>
<td>Selects a value based on a series of independent tests.</td>
</tr>
<tr>
<td>IF</td>
<td>Selects one of two values depending on whether a conditional statement returns TRUE or FALSE.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLSTAT</td>
<td>Returns an indicator that a column is MISSING, NULL, or INVALID.</td>
</tr>
<tr>
<td>COLTEST</td>
<td>Performs conditional calculations to test whether a column is PRESENT, MISSING, NULL, or INVALID.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>Returns a date and time based on the format passed into the source column.</td>
</tr>
<tr>
<td>DATEDIFF</td>
<td>Returns the difference between two dates or datetimes.</td>
</tr>
<tr>
<td>DATENOW</td>
<td>Returns the current date and time.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPUTE</td>
<td>Returns the result of an arithmetic expression.</td>
</tr>
</tbody>
</table>
### Table 5–5  Working with Strings

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBIN</td>
<td>Converts a binary string into a number.</td>
</tr>
<tr>
<td>NUMSTR</td>
<td>Converts a string into a number.</td>
</tr>
<tr>
<td>STRCAT</td>
<td>Concatenates one or more strings.</td>
</tr>
<tr>
<td>STRCMP</td>
<td>Compares two strings.</td>
</tr>
<tr>
<td>STREXT</td>
<td>Extracts a portion of a string.</td>
</tr>
<tr>
<td>STREQ</td>
<td>Determines whether or not two strings are equal.</td>
</tr>
<tr>
<td>STRFIND</td>
<td>Finds the occurrence of a string within a string.</td>
</tr>
<tr>
<td>STRLEN</td>
<td>Returns the length of a string.</td>
</tr>
<tr>
<td>STRLTRIM</td>
<td>Trims leading spaces.</td>
</tr>
<tr>
<td>STRNCAT</td>
<td>Concatenates one or more strings to a maximum length.</td>
</tr>
<tr>
<td>STRNCMP</td>
<td>Compares two strings based on a specified number of characters.</td>
</tr>
<tr>
<td>STRNUM</td>
<td>Converts a number into a string.</td>
</tr>
<tr>
<td>STRRTRIM</td>
<td>Trims trailing spaces.</td>
</tr>
<tr>
<td>STRSUB</td>
<td>Substitutes one string for another.</td>
</tr>
<tr>
<td>STRTRIM</td>
<td>Trims leading and trailing spaces.</td>
</tr>
<tr>
<td>STRUP</td>
<td>Changes a string to uppercase.</td>
</tr>
<tr>
<td>VALONEOF</td>
<td>Compares a string or string column to a list of values.</td>
</tr>
</tbody>
</table>

### Table 5–6  Other Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFTER</td>
<td>Returns the after image of the specified column.</td>
</tr>
<tr>
<td>BEFORE</td>
<td>Returns the before image of the specified column.</td>
</tr>
<tr>
<td>BEFOREAFTER</td>
<td>Returns the before image of the specified column, if available, otherwise returns the after image.</td>
</tr>
<tr>
<td>BINARY</td>
<td>Maintains source binary data as binary data in the target column when the source column is defined as a character column.</td>
</tr>
<tr>
<td>BINTOHEX</td>
<td>Converts a binary string to a hexadecimal string.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Returns environmental information.</td>
</tr>
<tr>
<td>GETVAL</td>
<td>Extracts parameters from a stored procedure as input to a FILTER or COLMAP clause.</td>
</tr>
<tr>
<td>HEXTOBIN</td>
<td>Converts a hexadecimal string to a binary string.</td>
</tr>
<tr>
<td>HIGHVAL</td>
<td>Constrains a value to a high or low value.</td>
</tr>
<tr>
<td>LOWVAL</td>
<td></td>
</tr>
<tr>
<td>RANGE</td>
<td>Divides rows into multiple groups of data for parallel processing.</td>
</tr>
<tr>
<td>TOKEN</td>
<td>Retrieves token data from a trail record header.</td>
</tr>
</tbody>
</table>
Use the @AFTER function to return the after image of the specified source column. This is the default behavior.

**Syntax**

```
@AFTER (column)
```

*column*

The name of the source column for which to return the after image.

**Example**

```
@AFTER (quantity)
```
Use the @BEFORE function to return the before image of the specified source column. When using this parameter, use the GETUPDATEBEFOREES parameter in the Extract parameter file to capture before images from the transaction record, or use it in the Replicat parameter file to use the before image in a column mapping or filter. If using the Conflict Resolution and Detection (CDR) feature, you can use the GETBEFORECOLS option of TABLE. To use these parameters, the specified column must be present in the transaction log.

If the database only logs values for changed columns, make certain the required column values are available by enabling supplemental logging for those columns. Alternatively, you can use the FETCHCOLS or FETCHCOLEXCEPT option of the TABLE parameter. The fetch option involves additional processing overhead.

Syntax

@BEFORE (column)

column
The name of the source column for which to return the before image.

Example

@BEFORE (quantity)
Use the `@BEFOREAFTER` function to return the before image if available, or otherwise the after image.

When using this parameter, use the `GETUPDATEBEFORE` parameter in the Extract parameter file to capture before images from the transaction record, or use it in the Replicat parameter file to use the before image in a column mapping or filter. If using the Conflict Resolution and Detection (CDR) feature, you can use the `GETBEFORECOLS` option of `TABLE`. To use these parameters, all columns must be present in the transaction log.

If the database only logs values for changed columns, make certain the required column values are available by enabling supplemental logging for those columns. Alternatively, you can use the `FETCHCOLS` or `FETCHCOLSEXCEPT` option of the `TABLE` parameter. The fetch option involves additional processing overhead.

**Syntax**

```
@BEFOREAFTER (column)
```

`column`
The name of the source column for which to return the before image, if available, or otherwise the after image.

**Example**

```
@BEFOREAFTER (quantity)
```
Use the @BINARY function when a source column referenced by a column-conversion function is defined as a character column but contains binary data that must remain binary on the target. By default, binary data in a character column is converted (if necessary) to ASCII and assumed to be a null-terminated string. The @BINARY function copies arbitrary binary data to the target column.

Syntax

@BINARY (column)

column
The name of the target column to which the data will be copied.

Example

The following shows how @BINARY can be used to copy the data from the source column ACCT_CREATE_DATE to the target column ACCT_COMPLAINT.

ACCT_COMPLAINT =
@if ( @NUMBIN (ACCT_CREATE_DATE ) < 48633, 'xxxxxx',
@BINARY (ACCT_COMPLAINT))
BINTOHEX

Use the @BINTOHEX function to convert supplied binary data into its hexadecimal equivalent.

Syntax

@BINTOHEX (data)

data
Can be one of the following:
- The name of the source column that contains the data
- An expression
- A literal string that is enclosed within single quote marks

Example

@BINTOHEX ('12345') converts to 3132333435.
**CASE**

Use the `@CASE` function to select a value depending on a series of value tests. There is no limit to the number of cases you can test with `@CASE`. If the number of cases is large, list the most frequently encountered conditions first for the best performance.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support `NCHAR` or `NVARCHAR` data types.

**Syntax**

```sql
@CASE (value, test_value1, test_result1
[, test_value2, test_result2] [, ...
[, default_result]
```

- **value**
  A value to test, for example, a column name. Enclose literals within single quote marks.

- **test_value**
  A valid result for `value`. Enclose literals within single quote marks.

- **test_result**
  A value to return based on the value of `test_value`. Enclose literals within single quote marks.

- **default_result**
  A default value to return if `value` results in none of the `test_value` values. Enclose literals within single quote marks.

**Examples**

**Example 1**

The following returns *A car* if `PRODUCT_CODE` is `CAR` and *A truck* if `PRODUCT_CODE` is `TRUCK`. If `PRODUCT_CODE` fits neither of the first two cases, a FIELD_MISSING indication is returned because a default value was not specified.

```sql
@CASE (PRODUCT_CODE, 'CAR', 'A car', 'TRUCK', 'A truck')
```

**Example 2**

The following is similar to the previous example, except that it provides for a default value. If `PRODUCT_CODE` is neither `CAR` nor `TRUCK`, the function returns *A vehicle*.

```sql
@CASE (PRODUCT_CODE, 'CAR', 'A car', 'TRUCK', 'A truck', 'A vehicle')
```
Use the @COLSTAT function to return an indicator to Extract or Replicat that a column is missing, null, or invalid. The indicator can be used as part of a larger manipulation formula that uses additional conversion functions.

**Syntax**

@COLSTAT ( {MISSING | NULL | INVALID} )

**Examples**

**Example 1**
The following example returns a NULL into target column ITEM.

ITEM = @COLSTAT ( NULL )

**Example 2**
The following @IF calculation uses @COLSTAT to return NULL to the target column if PRICE and QUANTITY are less than zero.

ORDER_TOTAL = PRICE * QUANTITY, @IF ( PRICE < 0 AND QUANTITY < 0, @COLSTAT(NULL) )
Use the @COLTEST function to enable conditional calculations by testing for one or more column conditions. If a condition is satisfied, @COLTEST returns TRUE. To perform the conditional calculation, use the @IF function.

**Syntax**

```
@COLTEST (source_column, test_condition [, test_condition] [, ...])
```

*source_column*

The name of a source column.

*test_condition*

Valid values:

- **PRESENT**
  Indicates a column is present in the source record and not NULL. Column values can be missing if the database does not log values for columns that do not change, but that is not the same as NULL.

- **NULL**
  Indicates a column is present in the source record and NULL.

- **MISSING**
  Indicates a column is not present in the source record.

- **INVALID**
  Indicates a column is present in the source record but contains invalid data.

**Examples**

**Example 1**

The following example uses @IF to map a value to the HIGH_SALARY column only if the BASE_SALARY column in the source record was both present (and not NULL) and greater than 250000. Otherwise, NULL is returned.

```
HIGH_SALARY = @IF (@COLTEST (BASE_SALARY, PRESENT) AND BASE_SALARY > 250000, BASE_SALARY, @COLSTAT (NULL))
```

**Example 2**

In the following example, 0 is returned when the AMT column is missing or invalid; otherwise a value for AMT is returned.

```
AMOUNT = @IF (@COLTEST (AMT, MISSING, INVALID), 0, AMT)
```
Use the @COMPUTE function to return the value of an arithmetic expression to a target column. The value returned from the function is in the form of a string.

You can omit the @COMPUTE phrase when returning the value of an arithmetic expression to another Oracle GoldenGate function, as in:

```
@STRNUM ((AMOUNT1 + AMOUNT2), LEFT)
```

The preceding returns the same result as:

```
@STRNUM (@COMPUTE (AMOUNT1 + AMOUNT2), LEFT)
```

Arithmetic expressions can be combinations of the following elements.

- Numbers
- The names of columns that contain numbers
- Functions that return numbers
- Arithmetic operators:
  - + (plus)
  - - (minus)
  - * (multiply)
  - / (divide)
  - \ (remainder)
- Comparison operators:
  - > (greater than)
  - >= (greater than or equal)
  - < (less than)
  - <= (less than or equal)
  - = (equal)
  - <> (not equal)
- Parentheses (for grouping results in the expression)
- The conjunction operators AND, OR. Oracle GoldenGate only evaluates the necessary part of a conjunction expression. Once a statement is FALSE, the rest of the expression is ignored. This can be valuable when evaluating fields that may be missing or null. For example, if the value of COL1 is 25 and the value of COL2 is 10, then the following are possible:

  - `@COMPUTE (COL1 > 0 AND COL2 < 3)` returns 0.
  - `@COMPUTE (COL1 < 0 AND COL2 < 3)` returns 0. COL2 < 3 is never evaluated.
  - `@COMPUTE ((COL1 + COL2)/5)` returns 7.
Syntax

@COMPUTE (expression)

**expression**
A valid arithmetic expression. The numeric value plus the precision cannot be greater than 17 digits. If this limit is exceeded, @COMPUTE returns an error similar to the following.

```
2013-08-01 01:54:22  ERROR   OGG-01334  Error mapping data from column to column in function COMPUTE.
```

Examples

**Example 1**

```
AMOUNT_TOTAL = @COMPUTE (AMT + AMT2)
```

**Example 2**

```
AMOUNT_TOTAL = @IF (AMT >= 0, AMT * 100, 0)
```

**Example 3**

```
ANNUAL_SALARY = @COMPUTE (MONTHLY_SALARY * 12)
```
Use the @DATE function to return dates and times in a variety of formats to the target column based on the format passed into the source column. @DATE converts virtually any type of input into a valid SQL date. @DATE also can be used to extract portions of a date column or to compute a numeric timestamp column based on a date.

Syntax

@DATE ("output_descriptor", "input_descriptor", source_column [, "input_descriptor", source_column] [, ...])

'output_descriptor'
The output of the function. The valid value is a string that is composed of date descriptors and optional literal values, such as spaces or colons, that are required by the target column. Date descriptors can be strung together as needed. See Table 5–7 for descriptions of date descriptors. The format descriptor must match the date/time/timestamp format for the target. Oracle GoldenGate overrides the specified format to make it correct, if necessary.

'input_descriptor'
The source input. The valid value is a string that is composed of date descriptors and optional literal values, such as spaces or colons. Date descriptors can be strung together as needed. The following are examples:

- Descriptor string 'YYYYMMDD' indicates that the source column specified with source_column contains (in order) a four-digit year (YYYY), month (MM), and day (DD).
- Descriptor string 'DD/MM/YY' indicates that the source column specified with source_column contains the day, a slash, the month, a slash, and the two digit year.

See Table 5–7 for date descriptions.

source_column
The name of the numeric or character source column that supplies the input specified with input_descriptor.

Table 5–7  Date Descriptors

<table>
<thead>
<tr>
<th>Descriptor</th>
<th>Description</th>
<th>Valid for...</th>
</tr>
</thead>
<tbody>
<tr>
<td>CC</td>
<td>Century</td>
<td>Input/Output</td>
</tr>
<tr>
<td>YY</td>
<td>Two-digit year</td>
<td>Input/Output</td>
</tr>
<tr>
<td>YYYY</td>
<td>Four-digit year</td>
<td>Input/Output</td>
</tr>
<tr>
<td>MM</td>
<td>Numeric month</td>
<td>Input/Output</td>
</tr>
<tr>
<td>MMM</td>
<td>Alphanumeric month, such as APR, OCT</td>
<td>Input/Output</td>
</tr>
<tr>
<td>DD</td>
<td>Numeric day of month</td>
<td>Input/Output</td>
</tr>
<tr>
<td>DDD</td>
<td>Numeric day of the year, such as 001 or 365</td>
<td>Input/Output</td>
</tr>
<tr>
<td>DOW0</td>
<td>Numeric day of the week (Sunday = 0)</td>
<td>Input/Output</td>
</tr>
<tr>
<td>DOW1</td>
<td>Numeric day of the week (Sunday = 1)</td>
<td>Input/Output</td>
</tr>
<tr>
<td>DOWA</td>
<td>Alphanumeric day of the week, such as SUN, MON, TUE</td>
<td>Input/Output</td>
</tr>
<tr>
<td>HH</td>
<td>Hour</td>
<td>Input/Output</td>
</tr>
</tbody>
</table>
Example 1
In an instance where a two-digit year is supplied, but a four-digit year is required in the output, several options exist to obtain the correct century.

- The century can be hard coded, as in:
  'CC', 19 or 'CC', 20
- The @IF function can be used to set a condition, as in:
  'CC', @IF (YY > 70, 19, 20)

This causes the century to be set to 19 when the year is greater than 70; otherwise the century is set to 20.
- The system can calculate the century automatically. If the year is less than 50, the system calculates a century of 20; otherwise, a century of 19 is calculated.

Example 2
The following converts year, month and day columns into a date.

date_col = @DATE ('YYYY-MM-DD', 'YY', date1_yy, 'MM', date1_mm, 'DD', date1_dd)

Example 3
The following converts a date and time, defaulting seconds to zero.

date_col = @DATE ('YYYY-MM-DD HH:MI:00', 'YYMMDD', datel, 'HHMI', timel)

Example 4
The following converts a numeric column stored as YYYYMMDDHHMISS to a SQL date.

datetime_col = @DATE ('YYYY-MM-DD HH:MI:SS', 'YYYYMMDDHHMISS', numeric_date)
Example 5
The following converts a numeric column stored as YYYYMMDDHHMISS to a Julian timestamp.

julian_ts_col = @DATE ('JTS', 'YYYYMMDDHHMISS', numeric_date)

Example 6
The following converts a Julian timestamp column to two separate columns: a
datetime column in the format YYYY-MM-DD HH:MI:SS and a fraction column that holds
the microseconds portion of the timestamp.

datetime_col = @DATE ('YYYY-MM-DD HH:MI:SS', 'JTS', jts_field), fraction_col =
@DATE ('FFFFFF', 'JTS', jts_field)

Example 7
The following produces the time at which an order is filled. The inner @DATE
expression changes the order_taken column into a Julian timestamp, then adds the
order_minutes column converted into microseconds to this timestamp. The expression
is passed back as a new Julian timestamp to the outer @DATE expression, which
converts it back to a more readable date and time.

order_filled = @DATE ('YYYY-MM-DD HH:MI:SS', 'JTS', @DATE ('JTS',
'YYYYMMDDHHMISS', order_taken) + order_minutes * 60 * 1000000)

Example 8
The following does a full calculation of times. It goes from a source date column
named dt to a target column named dt5 that is to be converted to the date + 5 hours.
The calculation also goes from a source timestamp column named ts to a target
column named ts5 that is to be converted to the timestamp + 5 hours.

MAP scratch.t4, TARGET scratch.t4_copy,
COLMAP ( USEDEFAULTS,
dt5 = @DATE ('YYYY-MM-DD HH:MI:SS', 'JTS',
@COMPUTE (@DATE ('JTS', 'YYYY-MM-DD HH:MI:SS', dt) + 18000000000 ) ),
ts5 = @DATE ('YYYY-MM-DD HH:MI:SS.FFFFFF', 'JTS',
@COMPUTE ( @DATE ('JTS', 'YYYY-MM-DD HH:MI:SS.FFFFFF', ts) + 18000000000 ) ) ) ;
DATEDIFF

Use the @DATEDIFF function to calculate the difference between two dates or datetimes, in days or seconds.

Syntax

@DATEDIFF ("difference", "date", "date")

difference
The difference between the specified dates. Valid values can be:
- DD, which computes the difference in days.
- SS, which computes the difference in seconds.

date
A string within single quote marks, in the format of ‘YYYY-MM-DD[ HH:MM[:SS]]’, where * can be a colon (:) or a blank space, or the @DATENOW function without quotes to return the current date.

Examples

Example 1
The following calculates the number of days since the beginning of the year 2011.

YTD = @DATEDIFF ("DD", "2011-01-01", @DATENOW ())

Example 2
The following calculates the numerical day of the year. (@DATEDIFF returns 0 for 2011-01-01):

todays_day = @COMPUTE (@DATEDIFF ("DD", "2011-01-01", @DATENOW ()) +1)
DATENOW

Use the @DATENOW function to return the current date and time in the format YYYY-MM-DD HH:MI:SS. The date and time are returned in local time, including adjustments for Daylight Saving Time. @DATENOW takes no arguments.

Syntax

@DATENOW ()
Use the `@DDL` function to return information about a DDL operation.

**Syntax**

```bash
@DDL (\{TEXT | OPTYPE | OBJNAME | OBJTYPE | OBJOWNER\})
```

**OBJNAME**

Returns the name of the object that is affected by the DDL.

**OBJOWNER**

Returns the name of the owner of the object that is affected by the DDL.

**OBJTYPE**

Returns the type of object that is affected by the DDL, such as `TABLE` or `INDEX`.

**OPTYPE**

Returns the operation type of the DDL, such as `CREATE` or `ALTER`.

**TEXT**

Returns the first 200 characters of the text of the DDL statement.

**Example**

The following example uses the output from `@DDL` in an `EVENTACTIONS` shell command.

```bash
DDL INCLUDE OBJNAME src.t* &
EVENTACTIONS (SHELL ('echo The DDL text is var1> out.txt ', &
VAR var1 = @DDL (TEXT)));
```

The redirected output file might contain a string like this:

```
The DDL text is CREATE TABLE src.test_tab (col1 int);
```
EVAL

Use the @EVAL function to select a value based on a series of independent tests. There is no limit to the number of conditions you can test. If the number of cases is large, list the most frequently encountered conditions first for best performance.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

Syntax

@EVAL (condition, result
[condition, result] [, ....]
[, default_result])

condition
A conditional test using standard conditional operators. More than one condition can be specified.

result
A value or string to return based on the results of the conditional test. Enclose literals within single quote marks. Specify a result for each condition that is used.

default_result
A default result to return if none of the conditions is satisfied. A default result is optional.

Examples

Example 1
In the following example, if the AMOUNT column is greater than 10000, a result of high amount is returned. If AMOUNT is greater than 5000 (and less than or equal to 10000), a result of somewhat high is returned (unless the prior condition was satisfied). If neither condition is satisfied, a COLUMN_MISSING indication is returned because a default result is not specified.

AMOUNT_DESC = @EVAL (AMOUNT > 10000, 'high amount', AMOUNT > 5000, 'somewhat high')

Example 2
The following is a modification of the preceding example. It returns the same results, except that a default value is specified, and a result of lower is returned if AMOUNT is less than or equal to 5000.

@EVAL (AMOUNT > 10000, 'high amount', AMOUNT > 5000, 'somewhat high', 'lower')
Use the @GETENV function to return information about the Oracle GoldenGate environment. You can use the information as input into the following:

- Stored procedures or queries (with SQLEXEC)
- Column maps (with the COLMAP option of TABLE or MAP)
- User tokens (defined with the TOKENS option of TABLE and mapped to target columns by means of the @TOKENS function)
- The GET_ENV_VALUE user exit function (see "GET_ENV_VALUE" on page 6-44)

**Note:** All syntax options must be enclosed within quotes as shown in the syntax descriptions.

### Syntax

```
@GETENV (
  'LAG', 'unit' |
  'LASTERR', 'error_info' |
  'JULIANTIMESTAMP' |
  'RECSOUTPUT' |
  {'STATS'|'DELTASTATS'}, ['TABLE', 'table'], 'statistic' |
  'GGENVIRONMENT', 'environment_info' |
  'GGFILEHEADER', 'header_info' |
  'GGHEADER', 'header_info' |
  'RECORD', 'location_info' |
  'DBENVIRONMENT', 'database_info' |
  'TRANSACTION', 'transaction_info' |
  'OSVARIABLE', 'variable' |
  'TLFKEY', SYSKEY, unique_key
)
```

**'LAG', 'unit'**

Valid for Extract and Replicat.

Use the LAG option of @GETENV to return lag information. Lag is the difference between the time that a record was processed by Extract or Replicat and the timestamp of that record in the data source.

**Syntax**

```
@GETENV ('LAG', {'SEC'|'MSEC'|'MIN'})
```

**'SEC'**

Returns the lag in seconds. This is the default when a unit is not explicitly provided for LAG.

**'MSEC'**

Returns the lag in milliseconds.

**'MIN'**

Returns the lag in minutes.
'LASTERR', 'error_info'

Valid for Replicat.

Use the LASTERR option of @GETENV to return information about the last failed operation processed by Replicat.

Syntax

@GETENV ('LASTERR', ('DBERRNUM' | 'DBERRMSG' | 'OPTYPE' | 'ERRTYPE'))

'DBERRNUM'

Returns the database error number associated with the failed operation.

'DBERRMSG'

Returns the database error message associated with the failed operation.

'OPTYPE'

Returns the operation type that was attempted. For a list of Oracle GoldenGate operation types, see Administering Oracle GoldenGate for Windows and UNIX.

'ERRTYPE'

Returns the type of error. Possible results are:

- DB (for database errors)
- MAP (for errors in mapping)

'JULIANTIMESTAMP'

Valid for Extract and Replicat.

Use the JULIANTIMESTAMP option of @GETENV to return the current time in Julian format. The unit is microseconds (one millionth of a second). On a Windows machine, the value will be padded with zeros (0) because the granularity of the Windows timestamp is milliseconds (one thousandth of a second). For example, the following is a typical column mapping:

MAP dbo.tab8451, Target targ.tabjts, COLMAP (USEDEFAULTS, & JTSS = @GETENV ('JULIANTIMESTAMP') JTSFFFFFF = @date ('yyyy-mm-dd hh:mi:ss.ffffff', 'JTS', & @getenv ('JULIANTIMESTAMP') ) )

Possible values that the JTSS and JTSFFFFFF columns can have are:

212096320960773000 2010-12-17:16:42:40.773000
212096321536540000 2010-12-17:16:52:16.540000
212096322856385000 2010-12-17:17:14:16.385000
212096323062919000 2010-12-17:17:42.919000
212096380852787000 2010-12-18:09:20:52.787000

The last three digits (the microseconds) of the number all contain the padding of 0s.

Syntax

@GETENV ('JULIANTIMESTAMP')

'RECSOUTPUT'

Valid for Extract.
Use the RECSOUTPUT option of @GETENV to retrieve a current count of the number of records that Extract has written to the trail file since the process started. The returned value is not unique to a table or transaction, but instead for the Extract session itself. The count resets to 1 whenever Extract stops and then is started again.

**Syntax**

@GETENV ('RECSOUTPUT')

**{'STATS' | 'DELTASTATS'}, ['TABLE', 'table'], 'statistic'**

Valid for Extract and Replicat.

Use the STATS and DELTASTATS options of @GETENV to return the number of operations that were processed per table for any or all of the following:

- INSERT operations
- UPDATE operations
- DELETE operations
- TRUNCATE operations
- Total DML operations
- Total DDL operations
- Number of conflicts that occurred, if the Conflict Detection and Resolution (CDR) feature is used.
- Number of CDR resolutions that succeeded
- Number of CDR resolutions that failed

Any errors in the processing of this function, such as an unresolved table entry or incorrect syntax, returns a zero (0) for the requested statistics value.

**Understanding How Recurring Table Specifications Affect Operation Counts**

An Extract that is processing the same source table to multiple output trails returns statistics based on each localized output trail to which the table linked to @GETENV is written. For example, if Extract captures 100 inserts for table ABC and writes table ABC to three trails, the result for the @GETENV is 300

```plaintext
EXTRACT ABC
...
EXTTRAIL c:\ogg\dirdat\aa;
TABLE TEST.ABC;
EXTTRAIL c:\ogg\dirdat\bb;
TABLE TEST.ABC;
TABLE EMI, TOKENS (TOKEN-CNT = @GETENV ('STATS', 'TABLE', 'ABC', 'DML'));
EXTTRAIL c:\ogg\dirdat\cc;
TABLE TEST.ABC;
```

In the case of an Extract that writes a source table multiple times to a single output trail, or in the case of a Replicat that has multiple MAP statements for the same TARGET table, the statistics results are based on all matching TARGET entries. For example, if Replicat filters 20 rows for REGION 'WEST,' 10 rows for REGION 'EAST,' 5 rows for REGION 'NORTH,' and 2 rows for REGION 'SOUTH' (all for table ABC) the result of the @GETENV is 37.

```plaintext
REPLICAT ABC
...
MAP TEST.ABC, TARGET TEST.ABC, FILTER (@STREQ (REGION, 'WEST'));
```
MAP TEST.ABC, TARGET TEST.ABC, FILTER (@STREQ (REGION, 'EAST'));
MAP TEST.ABC, TARGET TEST.ABC, FILTER (@STREQ (REGION, 'NORTH'));
MAP TEST.ABC, TARGET TEST.ABC, FILTER (@STREQ (REGION, 'SOUTH'));
MAP TEST.EMI, TARGET TEST.EMI, 
    COLMAP (CNT = @GETENV ('STATS', 'TABLE', 'ABC', 'DML'));

Capturing Multiple Statistics
You can execute multiple instances of @GETENV to get counts for different operation types.

This example returns statistics only for INSERT and UPDATE operations:

REPLICAT TEST
.. ..
MAP TEST.ABC, TARGET TEST.ABC, COLMAP (USEDEFAULTS, IU = @COMPUTE (@GETENV &
    ('STATS', 'TABLE', 'ABC', 'DML') - (@GETENV ('STATS', 'TABLE', &
    'ABC', 'DELETE')));

This example returns statistics for DDL and TRUNCATE operations:

REPLICAT TEST2
.. ..
MAP TEST.ABC, TARGET TEST.ABC, COLMAP (USEDEFAULTS, DDL = @COMPUTE &
    (@GETENV ('STATS', 'DDL') + (@GETENV ('STATS', 'TRUNCATE')));

Example Use Case
In the following use case, if all DML from the source is applied successfully to the
 target, Replicat suspends by means of EVENTACTIONS with SUSPEND, until resumed from
 GGSCI with SEND REPLICAT with RESUME.

GETENV used in Extract parameter file:

TABLE HR1.HR*;
TABLE HR1.STAT, TOKENS ('env_stats' = @GETENV ('STATS', 'TABLE', &
    'HR1.HR*', 'DML'));

GETENV used in Replicat parameter file:

MAP HR1.HR*, TARGET HR2.*;
MAP HR1.STAT, TARGET HR2.STAT, filter {
    @if {
        @token ('stats') =
        @getenv ('STATS', 'TABLE', 'TSSCAT.TCUSTORD', 'DML'), 1, 0 )
    },
    eventactions (suspend);

Using statistics in FILTER clauses
Statistics returned by STATS and DELTASTATS are dynamic values and are incremented
after mapping is performed. Therefore, when using CDR statistics in a FILTER clause
in each of multiple MAP statements, you need to order the MAP statements in descending
order of the statistics values. If the order is not correct, Oracle GoldenGate returns
error OGG-01921. For detailed information about this requirement, see Document
1556241.1 in the Knowledge base of My Oracle Support (http://support.oracle.com).
**Example 5–1  MAP statements containing statistics in FILTER clauses**

In the following example, the MAP statements containing the filter for the CDR_CONFLICTS statistic are ordered in descending order of the statistic: >3, then =3, then <3.

```plaintext
MAP TEST.GG_HEARTBEAT_TABLE, TARGET TEST.GG_HEARTBEAT_TABLE COMPARECOLS (ON UPDATE ALL),
RESOLVECONFLICT (UPDATEROWEXISTS, (DEFAULT, OVERWRITE)),
FILTER (@GETENV ('STATS', 'CDR_CONFLICTS') > 3),
EVENTACTIONS (LOG INFO);

MAP TEST.GG_HEARTBEAT_TABLE, TARGET TEST.GG_HEARTBEAT_TABLE COMPARECOLS (ON UPDATE ALL),
RESOLVECONFLICT (UPDATEROWEXISTS, (DEFAULT, OVERWRITE)),
FILTER (@GETENV ('STATS', 'CDR_CONFLICTS') = 3),
EVENTACTIONS (LOG WARNING);

MAP TEST.GG_HEARTBEAT_TABLE, TARGET TEST.GG_HEARTBEAT_TABLE COMPARECOLS (ON UPDATE ALL),
RESOLVECONFLICT (UPDATEROWEXISTS, (DEFAULT, OVERWRITE)),
FILTER (@GETENV ('STATS', 'CDR_CONFLICTS') < 3),
EVENTACTIONS (LOG WARNING);
```

**Syntax**

@GETENV ({'STATS' | 'DELTASTATS'}, [‘TABLE’, ‘table’], ‘statistic’)  

### {'STATS' | 'DELTASTATS'}

STATS returns counts since process startup, whereas DELTASTATS returns counts since the last execution of a DELTASTATS.

The execution logic is as follows:

- When Extract processes a transaction record that satisfies @GETENV with STATS or DELTASTATS, the table name is matched against resolved source tables in the TABLE statement.

- When Replicat processes a trail record that satisfies @GETENV with STATS or DELTASTATS, the table name is matched against resolved target tables in the TARGET clause of the MAP statement.

### {'TABLE', 'table'}

Executes the STATS or DELTASTATS only for the specified table or tables. Without this option, counts are returned for all tables that are specified in TABLE (Extract) or MAP (Replicat) parameters in the parameter file.

Valid `table_name` values are:

- 'schema.table' specifies a table.
- 'table' specifies a table of the default schema.
- 'schema.*' specifies all tables of a schema.
- '*' specifies all tables of the default schema.

For example, the following counts DML operations only for tables in the hr schema:

```plaintext
MAP fin.*, TARGET fin.*;
MAP hr.*, TARGET hr.*;
MAP hq.rpt, TARGET hq.rpt, COLMAP (USEDEFAULTS, CNT = @GETENV ('STATS', 'TABLE', 'hr.*', 'DML'));
```

Likewise, the following counts DML operations only for the emp table in the hr schema:

```plaintext
MAP fin.*, TARGET fin.*;
```
MAP hr.*, TARGET hr.*;
MAP hq.rpt, TARGET hq.rpt, COLMAP (USEDEFAULTS, CNT = @GETENV ('STATS', 'TABLE', 'hr.emp', 'DML'));

By contrast, because there are no specific tables specified for STATS in the following example, the function counts all INSERT, UPDATE, and DELETE operations for all tables in all schemas that are represented in the TARGET clauses of MAP statements:

MAP fin.*, TARGET fin.*;
MAP hr.*, TARGET hr.*;
MAP hq.rpt, TARGET hq.rpt, COLMAP (USEDEFAULTS, CNT = & @GETENV ('STATS', 'DML'));

'statistic'
The type of statistic to return. See Section 5, "Using statistics in FILTER clauses" for important information when using statistics in FILTER clauses in multiple TABLE or MAP statements.

'INSERT'
Returns the number of INSERT operations that were processed.

'UPDATE'
Returns the number of UPDATE operations that were processed.

'DELETE'
Returns the number of DELETE operations that were processed.

'DML'
Returns the total of INSERT, UPDATE, and DELETE operations that were processed.

'TRUNCATE'
Returns the number of TRUNCATE operations that were processed. This variable returns a count only if Oracle GoldenGate DDL replication is not being used. If DDL replication is being used, this variable returns a zero.

'DDL'
Returns the number of DDL operations that were processed, including TRUNCATEs and DDL specified in INCLUDE and EXCLUDE clauses of the DDL parameter, all scopes (MAPE, UNMAPE, OTHER). This variable returns a count only if Oracle GoldenGate DDL replication is being used. This variable is not valid for 'DELTASTATS'.

'CDR_CONFLICTS'
Returns the number of conflicts that Replicat detected when executing the Conflict Detection and Resolution (CDR) feature.

Example for a specific table:
@GETENV ('STATS', 'TABLE', 'HR.EMP', 'CDR_CONFLICTS')

Example for all tables processed by Replicat:
@GETENV ('STATS', 'CDR_CONFLICTS')

'CDR_RESOLUTIONS_SUCCEEDED'
Returns the number of conflicts that Replicat resolved when executing the Conflict Detection and Resolution (CDR) feature.

Example for a specific table:
@GETENV ('STATS', 'TABLE', 'HR.EMP', 'CDR_RESOLUTIONS_SUCCEEDED')
Example for all tables processed by Replicat:

```plaintext
@GETENV ('STATS','CDR_RESOLUTIONS_SUCCEEDED')
```

'CDR_RESOLUTIONS_FAILED'

Returns the number of conflicts that Replicat could not resolve when executing the Conflict Detection and Resolution (CDR) feature.

Example for a specific table:

```plaintext
@GETENV ('STATS','TABLE','HR.EMP','CDR_RESOLUTIONS_FAILED')
```

Example for all tables processed by Replicat:

```plaintext
@GETENV ('STATS','CDR_RESOLUTIONS_FAILED')
```

'GGENVIRONMENT', 'environment_info'

Valid for Extract and Replicat.

Use the GGENVIRONMENT option of @GETENV to return information about the Oracle GoldenGate environment.

**Syntax**

```plaintext
@GETENV ('GGENVIRONMENT', {'DOMAINNAME'|'GROUPDESCRIPTION'|'GROUPNAME'|'GROUPTYPE'|'HOSTNAME'|'OSUSERNAME'|'PROCESSID'})
```

'DOMAINNAME'

(Windows only) Returns the domain name associated with the user that started the process.

'GROUPDESCRIPTION'

Returns the description of the group, taken from the checkpoint file. Requires that a description was provided with the *DESCRIPTION* parameter when the group was created with the *ADD* command in GGSCI.

'GROUPNAME'

Returns the name of the process group.

'GROUPTYPE'

Returns the type of process, either *EXTRACT* or *REPLICAT*.

'HOSTNAME'

Returns the name of the system running the Extract or Replicat process.

'OSUSERNAME'

Returns the operating system user name that started the process.

'PROCESSID'

Returns the process ID that is assigned to the process by the operating system.

'GGHEADER', 'header_info'

Valid for Extract and Replicat.

Use the GGHEADER option of @GETENV to return information from the header portion of an Oracle GoldenGate trail record. The header describes the transaction environment of the record. For more information on record headers and record types, see *Administering Oracle GoldenGate for Windows and UNIX*. 
**Syntax**

```c
@GETENV ('GGHEADER', {'BEFOREAFTERINDICATOR'|'COMMITTIMESTAMP'|'LOGPOSITION'|'LOGRBA'|'OBJECTNAME'|'TABLENAME'|'OPTYPE'|'RECORDLENGTH'|'TRANSACTIONINDICATOR'})
```

'**BEFOREAFTERINDICATOR**'

Returns the before or after indicator showing whether the record is a before image or an after image. Possible results are:

- BEFORE (before image)
- AFTER (after image)

'**COMMITTIMESTAMP**'

Returns the transaction timestamp (the time when the transaction committed) expressed in the format of `YYYY-MM-DD HH:MI:SS.FFFFFF`, for example:

```
2011-01-24 17:08:59.000000
```

'**LOGPOSITION**'

Returns the position of the Extract process in the data source. (See the LOGRBA option.)

'**LOGRBA**'

LOGRBA and LOGPOSITION store details of the position in the data source of the record. For transactional log-based products, LOGRBA is the sequence number and LOGPOSITION is the relative byte address. However, these values will vary depending on the capture method and database type.

'**OBJECTNAME**' | '**TABLENAME**'

Returns the table name or object name (if a non-table object).

'**OPTYPE**'

Returns the type of operation. Possible results are:

- INSERT
- UPDATE
- DELETE
- ENSCRIBE
- COMPUPDATE
- SQL
- COMPUPDATE
- PK
- UPDATE
- TRUNCATE

If the operation is not one of the above types, then the function returns the word TYPE with the number assigned to the type.

'**RECORDLENGTH**'

Returns the record length in bytes.

'**TRANSACTIONINDICATOR**'

Returns the transaction indicator. The value corresponds to the TransInd field of the record header, which can be viewed with the Logdump utility.

Possible results are:

- BEGIN (represents TransInd of 0, the first record of a transaction.)
- MIDDLE (represents TransInd of 1, a record in the middle of a transaction.)
- END (represents TransInd of 2, the last record of a transaction.)
- WHOLE (represents TransInd of 3, the only record in a transaction.)
'GGFILEHEADER' , 'header_info'
Valid for Replicat.

Use the GGFILEHEADER option of @GETENV to return attributes of an Oracle GoldenGate extract file or trail file. These attributes are stored as tokens in the file header.

---

**Note:** If a given database, operating system, or Oracle GoldenGate version does not provide information that relates to a given token, a NULL value will be returned.

---

**Syntax**

```
@GETENV ('GGFILEHEADER', {'COMPATIBILITY'|'CHARSET'|'CREATETIMESTAMP'|'FILENAME'|'FILETYPE'|'FILESEQNO'|'FILESIZE'|'FIRSTRECCSN'|'LASTRECCSN'|'FIRSTRECIOTIME'|'LASTRECIOTIME'|'URI'|'URIHISTORY'|'GROUPNAME'|'DATASOURCE'|'GGMAJORVERSION'|'GGMINORVERSION'|'GGVERSIONSTRING'|'GGMAINTENANCELEVEL'|'GGBUGFIXLEVEL'|'GGBUILDNUMBER'|'HOSTNAME'|'OSVERSION'|'OSRELEASE'|'OSTYPE'|'HARDWARETYPE'|'DBNAME'|'DBINSTANCE'|'DBTYPE'|'DBCHARSET'|'DBMAJORVERSION'|'DBMINORVERSION'|'DBVERSIONSTRING'|'DBCLIENTCHARSET'|'DBCLIENTVERSIONSTRING'|'RECOVERYMODE'|'LASTCOMPLETECSN'|'LASTCOMPLETEXIDS'|'LASTCSN'|'LASTXID'|'LASTCSNTS'})
```

**'COMPATIBILITY'**

Returns the Oracle GoldenGate compatibility level of the trail file. The compatibility level of the current Oracle GoldenGate version must be greater than, or equal to, the compatibility level of the trail file to be able to read the data records in that file. Current valid values are 0 or 1.

- 1 means that the trail file is of Oracle GoldenGate version 10.0 or later, which supports file headers that contain file versioning information.
- 0 means that the trail file is of an Oracle GoldenGate version that is older than 10.0. File headers are not supported in those releases. The 0 value is used for backward compatibility to those Oracle GoldenGate versions.

**'CHARSET'**

Returns the global character set of the trail file. For example:

WCP1252-1

**'CREATETIMESTAMP'**

Returns the time that the trail was created, in local GMT Julian time in INT64.

**'FILENAME'**

Returns the name of the trail file. Can be an absolute or relative path, with a forward or backward slash depending on the file system.

**'FILETYPE'**

Returns a numerical value indicating whether the trail file is a single file (such as one created for a batch run) or a sequentially numbered file that is part of a trail for online, continuous processing. The valid values are:

- 0 - EXTFILE
- 1 - EXTRAIL
- 2 - UNIFIED and EXTFILE
- 3 - UNIFIED and EXTRAIL
'FILESEQNO'
Returns the sequence number of the trail file, without any leading zeros. For example, if a file sequence number is aa000026, FILESEQNO returns 26.

'FILESIZE'
Returns the size of the trail file. It returns NULL on an active file and returns a size value when the file is full and the trail rolls over.

'FIRSTRECCSN'
Returns the commit sequence number (CSN) of the first record in the trail file. Value is NULL until the trail file is completed. For more information about the CSN, see Administering Oracle GoldenGate for Windows and UNIX.

'LASTRECCSN'
Returns the commit sequence number (CSN) of the last record in the trail file. Value is NULL until the trail file is completed. For more information about the CSN, see Administering Oracle GoldenGate for Windows and UNIX.

'FIRSTRECIOTIME'
Returns the time that the first record was written to the trail file. Value is NULL until the trail file is completed.

'LASTRECIOTIME'
Returns the time that the last record was written to the trail file. Value is NULL until the trail file is completed.

'URI'
Returns the universal resource identifier of the process that created the trail file, in the following format:

host_name:dir[:dir]:[dir_n]group_name

Where:
- host_name is the name of the server that hosts the process
- dir is a subdirectory of the Oracle GoldenGate installation path.
- group_name is the name of the process group that is linked with the process.

The following example shows where the trail was processed and by which process. This includes a history of previous runs.

sys1:home:oracle:v9.5:extora

'URIHISTORY'
Returns a list of the URIs of processes that wrote to the trail file before the current process.

- For a primary Extract, this field is empty.
- For a data pump, this field is URIHistory + URI of the input trail file.

'GROUPNAME'
Returns the name of the group that is associated with the Extract process that created the trail. The group name is the one that was supplied when the ADD EXTRACT command was issued.

'DATASOURCE'
Returns the data source that was read by the process. The return value can be one of the following:
■ DS_EXTRACT_TRAILS: The source was an Oracle GoldenGate extract file, populated with change data.

■ DS_DATABASE: The source was a direct select from database table written to a trail, used for SOURCEISTABLE-driven initial load.

■ DS_TRAN_LOGS: The source was the database transaction log.

■ DS_INITIAL_DATA_LOAD: The source was a direct select from database tables for an initial load.

■ DS_VAM_EXTRACT: The source was a vendor access module (VAM).

■ DS_VAM_TWO_PHASE_COMMIT: The source was a VAM trail.

'GGMAJORVERSION'
Returns the major version of the Extract process that created the trail, expressed as an integer. For example, if a version is 1.2.3, it returns 1.

'GGMINORVERSION'
Returns the minor version of the Extract process that created the trail, expressed as an integer. For example, if a version is 1.2.3, it returns 2.

'GGVERSIONSTRING'
Returns the maintenance (or patch) level of the Extract process that created the trail, expressed as an integer. For example, if a version is 1.2.3, it returns 3.

'GGMAINTENANCELEVEL'
Returns the maintenance version of the process (xx.xx.xx).

'GGBUGFIXLEVEL'
Returns the patch version of the process (xx.xx.xx.xx).

'GGBUILDNUMBER'
Returns the build number of the process.

'HOSTNAME'
Returns the DNS name of the machine where the Extract that wrote the trail is running. For example:

■ sysa
■ sysb
■ paris
■ hq25

'OSVERSION'
Returns the major version of the operating system of the machine where the Extract that wrote the trail is running. For example:

■ Version s10_69
■ #1 SMP Fri Feb 24 16:56:28 EST 2006
■ 5.00.2195 Service Pack 4

'OSRELEASE'
Returns the release version of the operating system of the machine where the Extract that wrote the trail is running. For example, release versions of the examples given for OSVERSION could be:
■ 5.10
■ 2.6.9-34.ELsmp

'OSTYPE'
Returns the type of operating system of the machine where the Extract that wrote the trail is running. For example:
■ SunOS
■ Linux
■ Microsoft Windows

'HARDWARETYPE'
Returns the type of hardware of the machine where the Extract that wrote the trail is running. For example:
■ sun4u
■ x86_64
■ x86

'DBNAME'
Returns the name of the database, for example findb.

'DBINSTANCE'
Returns the name of the database instance, if applicable to the database type, for example ORA1022A.

'DBTYPE'
Returns the type of database that produced the data in the trail file. Can be one of:
DB2 UDB
DB2 ZOS
CTREE
MSSQL
MYSQL
ORACLE
SQLMX
SYBASE
TERADATA
NONSTOP
ENSCRIBE
ODBC

'DBCHARSET'
Returns the character set that is used by the database that produced the data in the trail file. (For some databases, this will be empty.)

'DBMajorVersion'
Returns the major version of the database that produced the data in the trail file.

'DBMinorVersion'
Returns the minor version of the database that produced the data in the trail file.

'DBVersionString'
Returns the maintenance (patch) level of the database that produced the data in the trail file.
'DBCLIENTCHARSET'
Returns the character set that is used by the database client.

'DBCLIENTVERSIONSTRING'
Returns the maintenance (patch) level of the database client. (For some databases, this will be empty.)

'RECOVERYMODE'
Returns recovery information for internal Oracle GoldenGate use.

'LASTCOMPLETECSN'
Returns recovery information for internal Oracle GoldenGate use.

'LASTCOMPLETEXIDS'
Returns recovery information for internal Oracle GoldenGate use.

'LASTCSN'
Returns recovery information for internal Oracle GoldenGate use.

'LASTXID'
Returns recovery information for internal Oracle GoldenGate use.

'LASTCSNTS'
Returns recovery information for internal Oracle GoldenGate use.

'RECORD', 'location_info'
Valid for a data-pump Extract or Replicat.
Use the RECORD option of @GETENV to return the location or Oracle rowid of a record in an Oracle GoldenGate trail file.

Syntax
@GETENV ('RECORD', {'FILESEQNO'|'FILERBA'|'ROWID'|'RSN'|'TIMESTAMP'})

'FILESEQNO'
Returns the sequence number of the trail file without any leading zeros.

'FILERBA'
Returns the relative byte address of the record within the FILESEQNO file.

'ROWID'
(Valid for Oracle) Returns the rowid of the record.

'RSN'
Returns the record sequence number within the transaction.

'TIMESTAMP'
Returns the timestamp of the record.

'DBENVIRONMENT', 'database_info'
Valid for Extract and Replicat.
Use the DBENVIRONMENT option of @GETENV to return global environment information for a database.
**Syntax**

```c
@GETENV ('DBENVIRONMENT', {'DBNAME'|'DBVERSION'|'DBUSER'|'SERVERNAME'})
```

'**DBNAME**'
Returns the database name.

'**DBVERSION**'
Returns the database version.

'**DBUSER**'
Returns the database login user. Note that SQL Server does not log the user ID.

'**SERVERNAME**'
Returns the name of the server.

'**TRANSACTION**', 'transaction_info'
Valid for Extract and Replicat.

Use the `TRANSACTION` option of `@GETENV` to return information about a source transaction. This option is valid for the Extract process.

**Syntax**

```c
@GETENV ('TRANSACTION', {'TRANSACTIONID'|'XID'|'CSN'|'TIMESTAMP'|'NAME'|
   'USERID'|'USERNAME'|'PLANNAME' | 'LOGBSN' | 'REDOTHREAD'})
```

'**TRANSACTIONID**' | 'XID'
Returns the transaction ID number. Either `TRANSACTIONID` or `XID` can be used. The transaction ID and the CSN are associated with the first record of every transaction and are stored as tokens in the trail record. For each transaction ID, there is an associated CSN. Transaction ID tokens have no zero-padding on any platform, because they never get evaluated as relative values. They only get evaluated for whether they match or do not match. Note that in the trail, the transaction ID token is shown as `TRANID`.

'**CSN**'
Returns the commit sequence number (CSN). The CSN is not zero-padded when returned for these databases: Oracle, DB2 LUW, and DB2 z/OS. For all other supported databases, the CSN is zero-padded. In the case of the Sybase CSN, each substring that is delimited by a dot (.) will be padded to a length that does not change for that substring.

Note that in the trail, the CSN token is shown as `LOGCSN`. See the `TRANSACTIONID` | `XID` environment value for additional information about the CSN token.

For more information about the CSN, see *Administering Oracle GoldenGate for Windows and UNIX*.

'**TIMESTAMP**'
Returns the commit timestamp of the transaction.

'**NAME**'
Returns the transaction name, if available.

'**USERID**'
(Oracle) Returns the Oracle user ID of the database user that committed the last transaction.
'USERNAME'
(Oracle) Returns the Oracle user name of the database user that committed the last transaction.

'PLANNAME'
(DB2 on z/OS) Returns the plan name under which the current transaction was originally executed. The plan name is included in the begin unit of recovery log record.

'LOGBSN'
Returns the begin sequence number (BSN) in the transaction log. The BSN is the native sequence number that identifies the beginning of the oldest uncommitted transaction that is held in Extract memory. For example, given an Oracle database, the BSN would be expressed as a system change number (SCN). The BSN corresponds to the current I/O checkpoint value of Extract. This value can be obtained from the trail by Replicat when @GETENV ('TRANSACTION', 'LOGBSN') is used. This value also can be obtained by using the INFO REPLICAT command with the DETAIL option. The purpose of obtaining the BSN from Replicat is to get a recovery point for Extract in the event that a system failure or file system corruption makes the Extract checkpoint file unusable. See Administering Oracle GoldenGate for Windows and UNIX for more information about recovering the Extract position.

'REDOTHREAD'
Returns the thread number of a RAC node extract; on non-RAC node extracts the value is always 1. For data pump and Replicat, the thread id used by Extract capture of a RAC node is returned; on non-RAC, @GETENV() returns an error. Logdump shows the token, ORATHREADID, in the token section if the transaction is captured by Extract on a RAC node.

'OSVARIABLE', 'variable'
Valid for Extract and Replicat.
Use the OSVARIABLE option of @GETENV to return the string value of a specified operating-system environment variable.

Syntax
@GETENV ('OSVARIABLE', 'variable')

'variable'
The name of the variable. The search is an exact match of the supplied variable name. For example, the UNIX grep command would return all of the following variables, but @GETENV ('OSVARIABLE', 'HOME') would only return the value for HOME:

ANT_HOME=/usr/local/ant
JAVA_HOME=/usr/java/j2sdk1.4.2_10
HOME=/home/judyd
ORACLE_HOME=/rdbms/oracle/ora1022i/64

The search is case-sensitive if the operating system supports case-sensitivity.

'TLFKEY', SYSKEY, 'unique_key'
Valid for Extract and Replicat.
Use the TLFKEY option of @GETENV to associate a unique key with TLF/PTLF records in ACT's Base24 application. The 64-bit key is composed of the following concatenated items:
The number of seconds since 2000.
- The block number of the record in the TLF/PTLF block multiplied by ten.
- The node specified by the user (must be between 0 and 255).

**Syntax**

```plaintext
GETENV ('TLFKEY', SYSKEY, unique_key)
```

**SYSKEY, unique_key**
The NonStop node number of the source TLF/PTLF file. Do not enclose this syntax element in quotes.

Example:

```plaintext
GETENV ('TLFKEY', SYSKEY, 27)
```
GETVAL

Use the @GETVAL function to extract values from a stored procedure or query so that they can be used as input to a FILTER or COLMAP clause of a MAP or TABLE statement.

Whether or not a parameter value can be extracted with @GETVAL depends upon the following:

1. Whether or not the stored procedure or query executed successfully.
2. Whether or not the stored procedure or query results have expired.

When a value cannot be extracted, the @GETVAL function results in a "column missing" condition. Typically, this occurs for update operations if the database only logs values for columns that were changed.

Usually this means that the column cannot be mapped. To test for missing column values, use the @COLTEST function to test the result of @GETVAL, and then map an alternative value for the column to compensate for missing values, if desired. Or, to ensure that column values are available, you can use the FETCHCOLS or FETCHCOLSEXCEPT option of the TABLE or MAP parameter to fetch the values from the database if they are not present in the log. Enabling supplemental logging for the necessary columns also would work.

Syntax

@GETVAL (name.parameter)

name
The name of the stored procedure or query. When using S QLEXEC to execute the procedure or query, valid values are as follows:

For queries, use the logical name specified with the ID option of the S QLEXEC clause. ID is a required S QLEXEC argument for queries.

For stored procedures, use one of the following, depending on how many times the procedure is to be executed within a TABLE or MAP statement:

- For multiple executions, use the logical name defined by the ID clause of the S QLEXEC statement. ID is required for multiple executions of a procedure.
- For a single execution, use the actual stored procedure name.

parameter
Valid values are one of the following:

- The name of the parameter in the stored procedure or query from which the data will be extracted and passed to the column map.
- RETURN_VALUE, if extracting values returned by a stored procedure or query.

Alternate Syntax

With S QLEXEC, you can capture parameter results without explicitly using the @GETVAL keyword. Simply refer to the procedure name (or logical name if using a query or multiple instances of a procedure) and parameter in the following format:

{procedure_name | logical_name}.parameter
Examples, Standard Syntax

**Example 1**
The following enables each map statement to call the stored procedure `lookup` by referencing the logical names `lookup1` and `lookup2` within the `@GETVAL` function and refer appropriately to each set of results.

```
MAP schema.srctab, TARGET schema.targtab,
SQLEXEC (SPNAME lookup, ID lookup1, PARAMS (param1 = srccol)),
COLMAP (targcol1 = @GETVAL (lookup1.param2));
MAP schema.srctab, TARGET schema.targtab2,
SQLEXEC (SPNAME lookup, ID lookup2, PARAMS (param1 = srccol)),
COLMAP (targcol2 = @GETVAL (lookup2.param2));
```

**Example 2**
The following shows a single execution of the stored procedure `lookup`. In this case, the actual name of the procedure is used. A logical name is not needed.

```
MAP schema.tab1, TARGET schema.tab2,
SQLEXEC (SPNAME lookup, PARAMS (param1 = srccol)),
COLMAP (targcol = @GETVAL (lookup.param1));
```

**Example 3**
The following shows the execution of a query from which values are mapped with `@GETVAL`.

```
MAP sales.account, TARGET sales.newacct,
SQLEXEC (ID lookup,
QUERY ' select desc_col into desc_param from lookup_table ' 
' where code_col = :code_param ',
PARAMS (code_param = account_code)),
COLMAP (newacct_id = account_id, newacct_val = @GETVAL (lookup.desc_param));
```

Examples, Alternate Syntax

**Example 1**
In the following example, `@GETVAL` is called implicitly for the phrase `proc1.p2` without the `@GETVAL` keyword.

```
MAP test.tab1, TARGET test.tab2,
SQLEXEC (SPNAME proc1, ID myproc, PARAMS (p1 = sourcecol1)),
COLMAP (targcol1 = proc1.p2);
```

**Example 2**
In the following example, the `@GETVAL` function is called implicitly for the phrase `lookup.desc_param` without the `@GETVAL` keyword.

```
MAP sales.account, TARGET sales.newacct,
SQLEXEC (ID lookup,
QUERY ' select desc_col into desc_param from lookup_table ' 
' where code_col = :code_param ',
PARAMS (code_param = account_code)),
COLMAP (newacct_id = account_id, newacct_val = lookup.desc_param);
```
HEXTOBIN

Use the @HEXTOBIN function to convert a supplied string of hexadecimal data into raw format.

Syntax

@HEXTOBIN (data)

data
The name of the source column, an expression, or a literal string that is enclosed within double quote marks.

Example

@HEXTOBIN ('414243') converts to three bytes: 0x41 0x42 0x43.
HIGHVAL | LOWVAL

Use the @HIGHVAL and @LOWVAL functions when you need to generate a value, but you want to constrain it within an upper or lower limit. These functions emulate the COBOL functions of the same names.

Use @HIGHVAL and @LOWVAL only with string and binary data types. When using them with strings, only @STRNCMP is valid. Using them with decimal or date data types or with SQLEXEC operations can cause errors. DOUBLE data types result in -1 or 0 (Oracle NUMBER, no precision, no scale).

Syntax

@HIGHVAL ([length]) | @LOWVAL ([length])

length
Optional. Specifies the binary output length in bytes. The maximum value of length is the length of the target column.

Example

The following example assumes that the size of the group_level column is 5 bytes.

<table>
<thead>
<tr>
<th>Function statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_level = @HIGHVAL ()</td>
<td>{0xFF, 0xFF, 0xFF, 0xFF, 0xFF}</td>
</tr>
<tr>
<td>group_level = @LOWVAL ()</td>
<td>{0x00, 0x00, 0x00, 0x00, 0x00}</td>
</tr>
<tr>
<td>group_level = @HIGHVAL (3)</td>
<td>{0xFF, 0xFF, 0xFF}</td>
</tr>
<tr>
<td>group_level = @LOWVAL (3)</td>
<td>{0x00, 0x00, 0x00}</td>
</tr>
</tbody>
</table>
Use the @IF function to return one of two values, based on a condition. You can use the @IF function with other Oracle GoldenGate functions to begin a conditional argument that tests for one or more exception conditions. You can direct processing based on the results of the test. You can nest @IF statements, if needed.

**Syntax**

@IF (condition, value_if_non-zero, value_if-zero)

- **condition**
  A valid conditional expression or Oracle GoldenGate function. Use numeric operators (such as =, > or <) only for numeric comparisons. For character comparisons, use one of the character-comparison functions.

- **value_if_non-zero**
  Non-zero is considered true.

- **value_if_zero**
  Zero (0) is considered false.

**Examples**

**Example 1**
The following returns an amount only if the *AMT* column is greater than zero; otherwise zero is returned.

```
AMOUNT_COL = @IF (AMT > 0, AMT, 0)
```

**Example 2**
The following returns *WEST* if the *STATE* column is *CA*, *AZ* or *NV*; otherwise it returns *EAST*.

```
REGION = @IF (@VALONEOF (STATE, 'CA', 'AZ', 'NV'), 'WEST', 'EAST')
```

**Example 3**
The following returns the result of the *PRICE* column multiplied by the *QUANTITY* column if both columns are greater than 0. Otherwise, the @COLSTAT (NULL) function creates a NULL value in the target column.

```
ORDER_TOTAL = @IF (PRICE > 0 AND QUANTITY > 0, PRICE * QUANTITY, @COLSTAT (NULL))
```
NUMBIN

Use the @NUMBIN function to convert a binary string of eight or fewer bytes into a number. Use this function when the source column defines a byte stream that actually is a number represented as a string.

Syntax

@NUMBIN (source_column)

source_column
The name of the source column that contains the string to be converted.

Example

The following combines @NUMBIN and @DATE to transform a 48-bit column to a 64-bit Julian value for local time.

\[\text{DATE} = \text{@DATE ('JTSLCT', 'TTS' @NUMBIN (\text{DATE}))}\]
NUMSTR

Use the @NUMSTR function to convert a string (character) column or value into a number. Use @NUMSTR to do either of the following:

- Map a string (character) to a number.
- Use a string column that contains only numbers in an arithmetic expression.

Syntax

@NUMSTR (input)

**input**
Can be either of the following:

- The name of a character column.
- A literal string that is enclosed within single quote marks.

Example

```
PAGE_NUM = @NUMSTR (ALPHA_PAGE_NO)
```
Use the @RANGE function to divide the rows of any table across two or more Oracle GoldenGate processes. It can be used to increase the throughput of large and heavily accessed tables and also can be used to divide data into sets for distribution to different destinations. Specify each range in a FILTER clause in a TABLE or MAP statement.

@RANGE is safe and scalable. It preserves data integrity by guaranteeing that the same row will always be processed by the same process group. To ensure that rows do not shift partitions to another process group and that the DML is performed in the correct order, the column on which you base the @RANGE partitioning must not ever change during a process run. Updates to the partition column may result in "row not found" errors or unique-constraint errors.

@RANGE computes a hash value of the columns specified in the input. If no columns are specified, the KEYCOLS clause of the TABLE or MAP statement is used to determine the columns to hash, if a KEYCOLS clause exists. Otherwise, the primary key columns are used.

Oracle GoldenGate adjusts the total number of ranges to optimize the even distribution across the number of ranges specified.

Because any columns can be specified for this function, rows in tables with relational constraints to one another must be grouped together into the same process or trail to preserve referential integrity.

**Note:** Using Extract to calculate the ranges is more efficient than using Replicat. Calculating ranges on the target side requires Replicat to read through the entire trail to find the data that meets each range specification.

**Syntax**

```sql
@RANGE (range, total_ranges [, column] [, column] [, ...])
```

*range*

The range assigned to the specified process or trail. Valid values are 1, 2, 3, and so forth, with the maximum value being the value defined by total_ranges.

*total_ranges*

The total number of ranges allocated. For example, to divide data into three groups, use the value 3.

*column*

The name of a column on which to base the range allocation. This argument is optional. If not used, Oracle GoldenGate allocates ranges based on the table’s primary key.

**Examples**

**Example 1**

In the following example, the replication workload is split into three ranges (between three Replicat processes) based on the ID column of the source acct table.
(Replicat group 1 parameter file)
MAP sales.acct, TARGET sales.acct, FILTER (@RANGE (1, 3, ID));

(Replicat group 2 parameter file)
MAP sales.acct, TARGET sales.acct, FILTER (@RANGE (2, 3, ID));

(Replicat group 3 parameter file)
MAP sales.acct, TARGET sales.acct, FILTER (@RANGE (3, 3, ID));

Example 2
In the following example, one Extract process splits the processing load into two trails. Since no columns were defined on which to base the range calculation, Oracle GoldenGate will use the primary key columns.
RMTTRAIL /ggs/dirdat/aa
TABLE fin.account, FILTER (@RANGE (1, 2));
RMTTRAIL /ggs/dirdat/bb
TABLE fin.account, FILTER (@RANGE (2, 2));

Example 3
In the following example, two tables have relative operations based on an order_ID column. The order_master table has a key of order_ID, and the order_detail table has a key of order_ID and item_number. Because the key order_ID establishes relativity, it is used in @RANGE filters for both tables to preserve referential integrity. The load is split into two ranges.

(Parameter file #1)
MAP sales.order_master, TARGET sales.order_master, FILTER (@RANGE (1, 2, order_ID));
MAP sales.order_detail, TARGET sales.order_detail, FILTER (@RANGE (1, 2, order_ID));

(Parameter file #2)
MAP sales.order_master, TARGET sales.order_master, FILTER (@RANGE (2, 2, order_ID));
MAP sales.order_detail, TARGET sales.order_detail, FILTER (@RANGE (2, 2, order_ID));
STRCAT

Use the \texttt{@STRCAT} function to concatenate one or more strings or string (character) columns. Enclose literal strings within single quote marks.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

Syntax

\texttt{@STRCAT \{string1, string2 [, ...]\}}

\textit{string1}

The first column or literal string to be concatenated.

\textit{string2}

The next column or literal string to be concatenated.

Example

The following creates a phone number from three columns and includes the literal formatting values.

\begin{verbatim}
PHONE_NO = @STRCAT (AREA_CODE, PREFIX, '-', PHONE)
\end{verbatim}
STRCMP

Use the @STRCMP function to compare two character columns or literal strings. Enclose literals within single quote marks.

@STRCMP returns the following:

- -1 if the first string is less than the second.
- 0 if the strings are equal.
- 1 if the first string is greater than the second.

Trailing spaces are truncated before comparing the strings.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems.

This function does not support NCHAR or NVARCHAR data types.

Syntax

@STRCMP (string1, string2)

string1
The first column or literal string to be compared.

string2
The second column or literal string to be compared.

Example

The following example compares two literal strings and returns 1 because the first string is greater than the second one.

@STRCMP ('JOHNSON', 'JONES')
Use the @STREQ function to determine whether or not two string (character) columns or literal strings are equal. Enclose literals within single quote marks. @STREQ returns the following:

- 1 (true) if the strings are equal.
- 0 (false) if the strings are not equal.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems.

Trailing spaces are truncated before comparing the strings.

This function does not support NCHAR or NVARCHAR data types.

**Syntax**

@STREQ (string1, string2)

*string1*

The first column or literal string to be compared.

*string2*

The second column or literal string to be compared.

**Example**

The following compares the value of the `region` column to the literal value `EAST`. If `region = EAST`, the record passes the filter.

FILTER (@STREQ (region, 'EAST'))

You could use @STREQ in a comparison to determine a result, as shown in the following example. If the state is `NY`, the expression returns `East Coast`. Otherwise, it returns `Other`.

@IF (@STREQ (state, 'NY'), 'East Coast', 'Other')
STREXT

Use the @STREXT function to extract a portion of a string.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support NCHAR or NVARCHAR data types.

Syntax

@STREXT (string, begin_position, end_position)

string
The string from which to extract. The string can be either the name of a character column or a literal string. Enclose literals within single quote marks.

begin_position
The byte position at which to begin extracting.

end_position
The byte position at which to end extracting. The end position is included in the extraction.

Example

The following example uses three @STREXT functions to extract a phone number into three different columns.

AREA_CODE = @STREXT (PHONE, 1, 3),
PREFIX = @STREXT (PHONE, 4, 6),
PHONE_NO = @STREXT (PHONE, 7, 10)
Use the `@STRFIND` function to determine the position of a string within a string column or else return zero if the string is not found. Optionally, `@STRFIND` can accept a starting position within the string.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support `NCHAR` or `NVARCHAR` data types.

**Syntax**

```sql
@STRFIND (string, 'search_string' [, begin_position])
```

- **string**
  The string in which to search. This can be either the name of a character column or a literal string that is within single quote marks.

- **'search_string'**
  The string for which to search. Enclose the search string within single quote marks.

- **begin_position**
  The byte position at which to begin searching.

**Example**

Assuming the string for the `ACCT` column is `ABC123ABC`, the following are possible results.

<table>
<thead>
<tr>
<th>Function statement</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>@STRFIND ('ACCT', '23')</code></td>
<td>5</td>
</tr>
<tr>
<td><code>@STRFIND ('ACCT', 'ZZ')</code></td>
<td>0</td>
</tr>
<tr>
<td><code>@STRFIND ('ACCT', 'ABC', 2)</code></td>
<td>7 (because the search started at the second byte)</td>
</tr>
</tbody>
</table>
Use the @STRLEN function to return the length of a string, expressed as the number of characters.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support NCHAR or NVARCHAR data types.

Syntax

@STRLEN (string)

string
The name of a string (character) column or a literal string. Enclose literals within single quote marks.

Examples

@STRLEN (ID_NO)

@STRLEN ('abcd')
STRLTRIM

Use the @STRLTRIM function to trim leading spaces.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

Syntax

@STRLTRIM (string)

string
The name of a character column or a literal string that is enclosed within single quote marks.

Example

birth_state = @strltrim (state)
STRNCAT

Use the $STRNCAT function to concatenate one or more strings to a maximum length. For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support `NCHAR` or `NVARCHAR` data types.

**Syntax**

$STRNCAT (string, max_length [, string, max_length] [, ...] )

*string*

The name of a string (character) column or a literal string that is enclosed within single quote marks.

*max_length*

The maximum string length, in characters.

**Example**

The following concatenates two strings and results in `ABC123`.

```
PHONE_NO = $STRNCAT ('ABCDEF', 3, '123456', 3)
```
Use the `@STRNCMP` function to compare two strings based on a specific number of bytes. The string can be either the name of a string (character) column or a literal string that is enclosed within single quote marks. The comparison starts at the first byte in the string.

`@STRNCMP` returns the following:

- `-1` if the first string is less than the second.
- `0` if the strings are equal.
- `1` if the first string is greater than the second.

This function does not support `NCHAR` or `NVARCHAR` data types.

### Syntax

```
@STRNCMP (string1, string2, max_length)
```

- **string1**
  The first string to be compared.

- **string2**
  The second string to be compared.

- **max_length**
  The maximum number of bytes in the string to compare.

### Example

The following example compares the first two bytes of each string, as specified by a `max_length` of 2, and it returns `0` because both sets are the same.

```
@STRNCMP ('JOHNSON', 'JONES', 2)
```
STRNUM

Use the @STRNUM function to convert a number into a string and specify the output format and padding.

**Syntax**

```
@STRNUM (column, (LEFT | LEFTSPACE, | RIGHT | RIGHTZERO) [length] )
```

- **column**
The name of a source numeric column.

- **LEFT**
Left justify, without padding.

- **LEFTSPACE**
Left justify, fill the rest of the target column with spaces.

- **RIGHT**
Right justify, fill the rest of the target column with spaces. If the value of a column is a negative value, the spaces are added before the minus sign. For example, `strnum(Col1, right)` used for a column value of -1.27 becomes ###-1.27, assuming the target column allows 7 digits. The minus sign is not counted as a digit, but the decimal is.

- **RIGHTZERO**
Right justify, fill the rest of the target column with zeros. If the value of a column is a negative value, the zeros are added after the minus sign and before the numbers. For example, `strnum(Col1, rightzero)` used for a column value of -1.27 becomes -0001.27, assuming the target column allows 7 digits. The minus sign is not counted as a digit, but the decimal is.

- **length**
Specifies the output length, when any of the options are used that specify padding (all but LEFT). For example:
  - `strnum(Col1, right, 6)` used for a column value of -1.27 becomes ##-1.27. The minus sign is not counted as a digit, but the decimal is.
  - `strnum(Col1, rightzero, 6)` used for a column value of -1.27 becomes -001.27. The minus sign is not counted as a digit, but the decimal is.

**Example**

Assuming a source column named NUM has a value of 15 and the target column's maximum length is 5 characters, the following examples show the different types of results obtained with formatting options.

<table>
<thead>
<tr>
<th>Function statement</th>
<th>Result (### denotes a space)</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CHAR1 = @STRNUM (NUM, LEFT)</code></td>
<td>15</td>
</tr>
<tr>
<td><code>CHAR1 = @STRNUM (NUM, LEFTSPACE)</code></td>
<td>15###</td>
</tr>
<tr>
<td><code>CHAR1 = @STRNUM (NUM, RIGHTZERO)</code></td>
<td>00015</td>
</tr>
<tr>
<td><code>CHAR1 = @STRNUM (NUM, RIGHT)</code></td>
<td>###15</td>
</tr>
</tbody>
</table>
If an output length of 4 is specified in the preceding example, the following shows the different types of results.

<table>
<thead>
<tr>
<th>Function statement</th>
<th>Result (# denotes a space)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR1 = @STRNUM (NUM, LEFTSPACE, 4)</td>
<td>15##</td>
</tr>
<tr>
<td>CHAR1 = @STRNUM (NUM, RIGHTZERO, 4)</td>
<td>0015</td>
</tr>
<tr>
<td>CHAR1 = @STRNUM (NUM, RIGHT, 4)</td>
<td>##15</td>
</tr>
</tbody>
</table>
STRRTRIM

Use the STRRTRIM function to trim trailing spaces.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

Syntax

@STRRTRIM (string)

string

The name of a character column or a literal string that is enclosed within single quote marks.

Example

street_address = @strrtrim (address)
**STRSUB**

Use the @STRSUB function to substitute strings within a string (character) column or constant. Enclose literal strings within single quote marks.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

Any single byte code value 1 to 255 can be used in hexadecimal or octal format for the string arguments. Hex values A to F are case insensitive and the leading 'x' must be lower case. Value zero (0) (\x00 and \000) is not allowed because it is a string terminator. No multibyte character set value or UNICODE values are supported.

This function does not support NCHAR or NVARCHAR data types.

**Syntax**

```sql
@STRSUB
(source_string, search_string, substitute_string
[, search_string, substitute_string] [, ...])
```

**source_string**

A source string, within single quotes, or the name of a source column that contains the characters for which substitution is to occur.

**search_string**

The string, within single quotes, for which substitution is to occur.

**substitute_string**

The string, within single quotes, that will be substituted for the search string.

**Examples**

**Example 1**

The following returns **xxABCxx**.

```sql
@STRSUB ('123ABC123', '123', 'xx')
```

**Example 2**

The following returns **023zBC023**.

```sql
@STRSUB ('123ABC123', 'A', 'z', '1', '0')
```

**Example 3**

The following is an example of replacing **\^Z**, using a hexadecimal string argument, with a space.

```sql
@strsub (col1, '\x1A', ' ');
```
Use the `@STRTRIM` function to trim leading and trailing spaces.
For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

**Syntax**

```
@STRTRIM (string)
```

*string*

The name of a character column or a literal string that is enclosed within single quote marks.

**Example**

```
pin_no = @strtrim (custpin)
```
STRUP

Use the `@STRUP` function to change an alphanumeric string or string (character) column to upper case.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support `NCHAR` or `NVARCHAR` data types.

Syntax

`@STRUP (string)`

string

The name of a character column or a literal string that is enclosed within single quote marks.

Example

The following returns `SALESPERSON`.

`@STRUP ('salesperson')`
Use the @TOKEN function to retrieve token data that is stored in the user token area of the Oracle GoldenGate record header. You can map token data to a target column by using @TOKEN in the source expression of a COLMAP clause. As an alternative, you can use @TOKEN within a SQLEXEC statement, an Oracle GoldenGate macro, or a user exit.

To define token data, use the TOKENS clause of the TABLE parameter in the Extract parameter file. For more information about using tokens, see Administering Oracle GoldenGate for Windows and UNIX.

**Syntax**

@TOKEN ('token')

`'token'`

The name, enclosed within single quote marks, of the token for which data is to be retrieved.

**Example**

In the following example, 10 tokens are mapped to target columns.

```sql
MAP ora.oratest, TARGET ora.rpt,
   COLMAP {
      host = @token ('tk_host'),
      gg_group = @token ('tk_group'),
      osuser = @token ('tk_osuser'),
      domain = @token ('tk_domain'),
      ba_ind = @token ('tk_ba_ind'),
      commit_ts = @token ('tk_commit_ts'),
      pos = @token ('tk_pos'),
      rba = @token ('tk_rba'),
      tablename = @token ('tk_table'),
      optype = @token ('tk_optype')
   };
```
Use the @VALONEOF function to compare a string or string (character) column to a list of values. If the value or column is in the list, 1 is returned; otherwise 0 is returned. This function trims trailing spaces before the comparison.

For this function, Oracle GoldenGate supports the use of an escape sequence to represent characters in a string column in Unicode or in the native character encoding of the Microsoft Windows, UNIX, and Linux operating systems. The target column must be a SQL Unicode data type if any argument is supplied as Unicode.

This function does not support NCHAR or NVARCHAR data types.

**Syntax**

@VALONEOF (expression, value [, value] [, ...])

*expression*

The name of a character column or a literal enclosed within single quote marks.

*value*

A criteria value.

**Example**

In the following example, if STATE is CA or NY, the expression returns COAST, which is the response returned by @IF when the value is non-zero (true). Otherwise, the expression returns MIDDLE.

@IF (@VALONEOF (STATE, 'CA', 'NY'), 'COAST', 'MIDDLE')
This chapter describes the Oracle GoldenGate user exit functions and their syntax and includes the following topics:

- Section 6.1, "Calling a User Exit"
- Section 6.2, "Summary of User Exit Functions"
- Section 6.3, "Using EXIT_CALL_TYPE"
- Section 6.4, "Using EXIT_CALL_RESULT"
- Section 6.5, "Using EXIT_PARAMS"
- Section 6.6, "Using ERCALLBACK"
- Section 6.7, "Function Codes"

For more information about using Oracle GoldenGate user exits, see Administering Oracle GoldenGate for Windows and UNIX.

### 6.1 Calling a User Exit

Write the user exit routine in C programming code. Use the CUSEREXIT parameter to call the user exit from a Windows DLL or UNIX shared object at a defined exit point within Oracle GoldenGate processing. Your user exit routine must be able to accept different events and information from the Extract and Replicat processes, process the information as desired, and return a response and information to the caller (the Oracle GoldenGate process that called it). For more information and syntax for the CUSEREXIT parameter, see "CUSEREXIT" on page 3-66.

### 6.2 Summary of User Exit Functions

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_CALL_TYPE</td>
<td>Indicates when, during processing, the routine is called.</td>
</tr>
<tr>
<td>EXIT_CALL_RESULT</td>
<td>Provides a response to the routine.</td>
</tr>
<tr>
<td>EXIT_PARAMS</td>
<td>Supplies information to the routine.</td>
</tr>
<tr>
<td>ERCALLBACK</td>
<td>Implements a callback routine. Callback routines retrieve record and Oracle GoldenGate context information, and they modify the contents of data records.</td>
</tr>
</tbody>
</table>
6.3 Using `EXIT_CALL_TYPE`

Use `EXIT_CALL_TYPE` to indicate when, during processing, the Extract or Replicat process (the caller) calls a user exit routine. A process can call a routine with the following calls.

Table 6–1  User Exit Calls

<table>
<thead>
<tr>
<th>Call type</th>
<th>Processing point</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>EXIT_CALL_ABORT_TRANS</code></td>
<td>Valid when the <code>RECOVERYOPTIONS</code> mode is <code>APPEND</code> (the default). Called when a data pump or Replicat reads a <code>RESTART ABEND</code> record from the trail, placed there by a writer process that abended. (The writer process can be the primary Extract writing to a local trail read by a data pump, or a data pump writing to a remote trail read by Replicat.) This call type enables the user exit to abort or discard the transaction that was left incomplete when the writer process stopped, and then to recover and resume processing at the start of the previous completed transaction.</td>
</tr>
<tr>
<td><code>EXIT_CALL_BEGIN_TRANS</code></td>
<td>Called just before either of the following:</td>
</tr>
<tr>
<td></td>
<td>■ a <code>BEGIN</code> record of a transaction that is read by a data pump</td>
</tr>
<tr>
<td></td>
<td>■ the start of a Replicat transaction</td>
</tr>
<tr>
<td><code>EXIT_CALL_CHECKPOINT</code></td>
<td>Called just before an Extract or Replicat checkpoint is written.</td>
</tr>
<tr>
<td><code>EXIT_CALL_DISCARD_ASCII_RECORD</code></td>
<td>Called during Extract processing before an ASCII input record is written to the discard file. The associated ASCII buffer can be retrieved and manipulated by the user exit using callback routines. This call type is not applicable for use with the Replicat process.</td>
</tr>
<tr>
<td><code>EXIT_CALL_DISCARD_RECORD</code></td>
<td>Called during Replicat processing before a record is written to the discard file. Records can be discarded for several reasons, such as when a value in the Oracle GoldenGate change record is different from the current version in the target table. The associated discard buffer can be retrieved and manipulated by the user exit using callback routines. This call type is not applicable for use with the Extract process.</td>
</tr>
<tr>
<td><code>EXIT_CALL_END_TRANS</code></td>
<td>Called just after either of the following:</td>
</tr>
<tr>
<td></td>
<td>■ an <code>END</code> record of a transaction that is read by a data pump</td>
</tr>
<tr>
<td></td>
<td>■ the last record in a Replicat transaction</td>
</tr>
<tr>
<td><code>EXIT_CALL_FATAL_ERROR</code></td>
<td>Called during Extract or Replicat processing just before Oracle GoldenGate terminates after a fatal error.</td>
</tr>
<tr>
<td><code>EXIT_CALL_PROCESS_MARKER</code></td>
<td>Called during Replicat processing when a marker from a NonStop server is read from the trail, and before writing to the marker history file.</td>
</tr>
</tbody>
</table>
Using EXIT_CALL_RESULT

Table 6–1  (Cont.) User Exit Calls

<table>
<thead>
<tr>
<th>Call type</th>
<th>Processing point</th>
</tr>
</thead>
</table>
| EXIT_CALL_PROCESS_RECORD | ■ For Extract, called before a record buffer is output to the trail.  
  ■ For Replicat, called just before a replicated operation is performed. This call is the basis of most user exit processing. When EXIT_CALL_PROCESS_RECORD is called, the record buffer and other record information are available to the user exit through callback routines. If source-target mapping is specified in the parameter file, the mapping is performed before the EXIT_CALL_PROCESS_RECORD event takes place. The user exit can map, transform, clean, or perform virtually any other operation with the record. The user exit can return a status indicating whether the caller should process or ignore the record.  
  When a user exit is used for a data-pump Extract that is configured in PASSTHRU mode, the user exit does not receive an EXIT_CALL_PROCESS_RECORD call. As a result, the user exit has no access to the DDL and DML operations. DDL operations are always processed by a data-pump Extract in PASSTHRU mode and cannot process DDL at all. If the data pump is configured in NOPASSTHRU mode (the default for DML), the user exit receives the EXIT_CALL_PROCESS_RECORD call only for DML operations. For more information, see PASSTHRU | NOPASSTHRU.                                                                                         |
| EXIT_CALL_START          | Called at the start of processing. The user exit can perform initialization work, such as opening files and initializing variables.                                                                           |
| EXIT_CALL_STOP           | Called before the process stops gracefully or ends abnormally. The user exit can perform completion work, such as closing files or outputting totals.                                                          |
| EXIT_CALL_RESULT         | Set by the user exit routines to instruct the caller how to respond when each exit call completes.                                                                                                                |

6.4 Using EXIT_CALL_RESULT

Use EXIT_CALL_RESULT to provide a response to the routine.

Table 6–2  User Exit Responses

<table>
<thead>
<tr>
<th>Call result</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_ABEND_VAL</td>
<td>Instructs the caller to terminate immediately.</td>
</tr>
<tr>
<td>EXIT_IGNORE_VAL</td>
<td>Rejects records for further processing. EXIT_IGNORE_VAL is appropriate when the user exit performs all the required processing for a record and there is no need to output or replicate the data record.</td>
</tr>
</tbody>
</table>
| EXIT_OK_VAL          | If the routine does nothing to respond to an event, EXIT_OK_VAL is assumed. If the exit call type is any of the following...  
  ■ EXIT_CALL_PROCESS_RECORD  
  ■ EXIT_CALL_DISCARD_RECORD  
  ■ EXIT_CALL_DISCARD_ASCII_RECORD  
  ... and EXIT_OK_VAL is returned, then Oracle GoldenGate processes the record buffer that was returned by the user exit. |
6.5 Using EXIT_PARAMS

Use EXIT_PARAMS to supply information to the user exit routine, such as the program name and user-defined parameters. You can process a single data record multiple times.

<table>
<thead>
<tr>
<th>Exit parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM_NAME</td>
<td>Specifies the full path and name of the calling process, for example \ggs\extract or \ggs\replicat. Use this parameter when loading an Oracle GoldenGate callback routine using the Windows API or to identify the calling program when user exits are used with both Extract and Replicat processing.</td>
</tr>
<tr>
<td>FUNCTION_PARAM</td>
<td>Allows you to pass a parameter that is a literal string to the user exit. Specify the parameter with the EXITPARAM option of the TABLE or MAP statement from which the parameter will be passed. See “EXITPARAM ‘parameter’” on page 3-324. This is only valid during the exit call to process a specific record. FUNCTION_PARAM can also be used at the exit call startup event to pass the parameters that are specified in the PARAMS option of the CUSEREXIT parameter. (See “CUSEREXIT” on page 3-66.) This is only valid to supply a global parameter at exit startup.</td>
</tr>
<tr>
<td>MORE_RECS_IND</td>
<td>Set on return from an exit. For database records, determines whether Extract or Replicat processes the record again. This allows the user exit to output many records per record processed by Extract, a common function when converting Enscribe to SQL (data normalization). To request the same record again, set MORE_RECS_IND to CHAR_NO_VAL or CHAR_YES_VAL.</td>
</tr>
</tbody>
</table>

6.6 Using ERCALLBACK

Use ERCALLBACK to execute a callback routine. A user callback routine retrieves context information from the Extract or Replicat process and sets context values, including the record itself, when the call type is one of the following:

- EXIT_CALL_PROCESS_RECORD
- EXIT_CALL_DISCARD_RECORD
- EXIT_CALL_DISCARD_ASCII_RECORD

Syntax

ERCALLBACK (function_code, buffer, result_code);

function_code
The function to be executed by the callback routine. The user callback routine behaves differently based on the function code passed to the callback routine. While some functions can be used for both Extract and Replicat, the validity of the function in one process or the other is dependent on the input parameters that are set for that function during the callback routine. See Section 6.7, “Function Codes” for a full description of available function codes.

buffer
A void pointer to a buffer containing a predefined structure associated with the specified function code.

result_code
The status of the function executed by the callback routine. The result code returned by the callback routine indicates whether or not the callback function was successful. A result code can be one of the values in Table 6–4.
**Table 6–4  Result Codes**

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXIT_FN_RET_BAD_COLUMN_DATA</td>
<td>Invalid data was encountered when retrieving or setting column data.</td>
</tr>
<tr>
<td>EXIT_FN_RET_BAD_DATE_TIME</td>
<td>A date, timestamp, or interval type of column contains an invalid date or time value.</td>
</tr>
<tr>
<td>EXIT_FN_RET_BAD_NUMERIC_VALUE</td>
<td>A numeric type of column contains an invalid numeric value.</td>
</tr>
<tr>
<td>EXIT_FN_RET_COLUMN_NOT_FOUND</td>
<td>The column was not found in a compressed update record (update by a database that only logs the values that were changed).</td>
</tr>
<tr>
<td>EXIT_FN_RET_ENV_NOT_FOUND</td>
<td>The specified environment value could not be found in the record.</td>
</tr>
<tr>
<td>EXIT_FN_RET_EXCEEDED_MAX_LENGTH</td>
<td>The metadata could not be retrieved because the name of the table or column did not fit in the allocated buffer.</td>
</tr>
<tr>
<td>EXIT_FN_RET_FETCH_ERROR</td>
<td>The record could not be fetched. View the error message to see the reason.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INCOMPLETE_DDL_REC</td>
<td>An internal error occurred when processing the DDL record. The record is probably incomplete.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INVALID_CALLBACK_FNC_CD</td>
<td>An invalid callback function code was passed to the callback routine.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INVALID_COLUMN</td>
<td>A non-existent column was referred to in the function call.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INVALID_COLUMN_TYPE</td>
<td>The routine is trying to manipulate a data type that is not supported by Oracle GoldenGate for that purpose.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INVALID_CONTEXT</td>
<td>The callback function was called at an improper time.</td>
</tr>
<tr>
<td>EXIT_FN_RET_INVALID_PARAM</td>
<td>An invalid parameter was passed to the callback function.</td>
</tr>
<tr>
<td>EXIT_FN_RET_NO_SRCDB_INSTANCE</td>
<td>The source database instance could not be found.</td>
</tr>
<tr>
<td>EXIT_FN_RET_NO_TGTDB_INSTANCE</td>
<td>The target database instance could not be found.</td>
</tr>
<tr>
<td>EXIT_FN_RET_NOT_SUPPORTED</td>
<td>This function is not supported for this process.</td>
</tr>
<tr>
<td>EXIT_FN_RET_OK</td>
<td>The callback function succeeded.</td>
</tr>
<tr>
<td>EXIT_FN_RET_SESSION_CS_CNV_ERR</td>
<td>A ULIB_ERR_INVALID_CHAR_FOUND error was returned to the character-set conversion routine. The conversion failed.</td>
</tr>
<tr>
<td>EXIT_FN_RET_TABLE_NOT_FOUND</td>
<td>An invalid table name was specified.</td>
</tr>
<tr>
<td>EXIT_FN_RET_TOKEN_NOT_FOUND</td>
<td>The specified user token could not be found in the record.</td>
</tr>
</tbody>
</table>

**6.7 Function Codes**

Function codes determine the output of the callback routine. The callback routine expects the contents of the data buffer to match the structure of the specified function code. The callback routine function codes and their data buffers are described in the following sections. The following is a summary of available functions.
### Table 6-5  Summary of Oracle GoldenGate Function Codes

<table>
<thead>
<tr>
<th>Function code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPRESS_RECORD</td>
<td>Use the COMPRESS_RECORD function when some, but not all, of a target table’s columns are present after mapping and the entire record must be manipulated, rather than individual column values.</td>
</tr>
<tr>
<td>DECOMPRESS_RECORD</td>
<td>Use the DECOMPRESS_RECORD function when some, but not all, of a target table’s columns are present after mapping and the entire record must be manipulated, rather than individual column values.</td>
</tr>
<tr>
<td>GET_BASE_OBJECT_NAME</td>
<td>Use the GET_BASE_OBJECT_NAME function to retrieve the fully qualified name of the base object of an object in a record.</td>
</tr>
<tr>
<td>GET_BASE_OBJECT_NAME_ONLY</td>
<td>Use the GET_BASE_OBJECT_NAME_ONLY function to retrieve only the name of the base object of an object in a record.</td>
</tr>
<tr>
<td>GET_BASE_SCHEMA_NAME_ONLY</td>
<td>Use the GET_BASE_SCHEMA_NAME_ONLY function to retrieve only the name of the schema of the base object of an object in a record.</td>
</tr>
<tr>
<td>GET_BEFORE_AFTER_IND</td>
<td>Use the GET_BEFORE_AFTER_IND function to determine whether a record is a before image or an after image of the database operation.</td>
</tr>
<tr>
<td>GET_CATALOG_NAME_ONLY</td>
<td>Use the GET_CATALOG_NAME_ONLY function to return the name of the database catalog.</td>
</tr>
<tr>
<td>GET_COL_METADATA_FROM_INDEX</td>
<td>Use the GET_COL_METADATA_FROM_INDEX function to determine the column metadata that is associated with a specified column index.</td>
</tr>
<tr>
<td>GET_COL_METADATA_FROM_NAME</td>
<td>Use the GET_COL_METADATA_FROM_NAME function to determine the column metadata that is associated with a specified column name.</td>
</tr>
<tr>
<td>GET_COLUMN_INDEX_FROM_NAME</td>
<td>Use the GET_COLUMN_INDEX_FROM_NAME function to determine the column index associated with a specified column name.</td>

### Table 6–5  (Cont.) Summary of Oracle GoldenGate Function Codes

<table>
<thead>
<tr>
<th>Function code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_RECORD_BUFFER</td>
<td>Use the <code>GET_RECORD_BUFFER</code> function to obtain information for custom column conversions.</td>
</tr>
<tr>
<td>GET_RECORD_LENGTH</td>
<td>Use the <code>GET_RECORD_LENGTH</code> function to return the length of the data record.</td>
</tr>
<tr>
<td>GET_RECORD_TYPE</td>
<td>Use the <code>GET_RECORD_TYPE</code> function to return the type of record being processed.</td>
</tr>
<tr>
<td>GET_SCHEMA_NAME_ONLY</td>
<td>Use the <code>GET_SCHEMA_NAME_ONLY</code> function to return only the schema name of a table.</td>
</tr>
<tr>
<td>GET_SESSION_CHARSET</td>
<td>Use the <code>GET_SESSION_CHARSET</code> function to return the character set of the user exit session.</td>
</tr>
<tr>
<td>GET_STATISTICS</td>
<td>Use the <code>GET_STATISTICS</code> function to return the current processing statistics for the Extract or Replicat process.</td>
</tr>
<tr>
<td>GET_TABLE_COLUMN_COUNT</td>
<td>Use the <code>GET_TABLE_COLUMN_COUNT</code> function to return the total number of columns in a table.</td>
</tr>
<tr>
<td>GET_TABLE_METADATA</td>
<td>Use the <code>GET_TABLE_METADATA</code> function to return metadata for the table that associated with the record that is being processed.</td>
</tr>
<tr>
<td>GET_TABLE_NAME</td>
<td>Use the <code>GET_TABLE_NAME</code> function to return the fully qualified two- or three-part name of the source or target table that is associated with the record that is being processed.</td>
</tr>
<tr>
<td>GET_TABLE_NAME_ONLY</td>
<td>Use the <code>GET_TABLE_NAME_ONLY</code> function to return only the unqualified name of the table that is associated with the record that is being processed.</td>
</tr>
<tr>
<td>GET_TIMESTAMP</td>
<td>Use the <code>GET_TIMESTAMP</code> function to return the I/O timestamp associated with a source data record.</td>
</tr>
<tr>
<td>GET_TRANSACTION_IND</td>
<td>Use the <code>GET_TRANSACTION_IND</code> function to determine whether a data record is the first, last or middle operation in a transaction.</td>
</tr>
<tr>
<td>GET_USER_TOKEN_VALUE</td>
<td>Use the <code>GET_USER_TOKEN_VALUE</code> function to obtain the value of a user token from a trail record.</td>
</tr>
<tr>
<td>OUTPUT_MESSAGE_TO_REPORT</td>
<td>Use the <code>OUTPUT_MESSAGE_TO_REPORT</code> function to output a message to the report file.</td>
</tr>
<tr>
<td>RESET_USEREXIT_STATS</td>
<td>Use the <code>RESET_USEREXIT_STATS</code> function to reset the statistics for the Oracle GoldenGate process.</td>
</tr>
<tr>
<td>SET_COLUMN_VALUE_BY_INDEX</td>
<td>Use the <code>SET_COLUMN_VALUE_BY_INDEX</code> function to modify a single column value without manipulating the entire data record.</td>
</tr>
<tr>
<td>STRNCMP</td>
<td>Use the <code>SET_COLUMN_VALUE_BY_NAME</code> function to modify a single column value without manipulating the entire data record.</td>
</tr>
<tr>
<td>SET_OPERATION_TYPE</td>
<td>Use the <code>SET_OPERATION_TYPE</code> function to change the operation type associated with a data record.</td>
</tr>
<tr>
<td>SET_RECORD_BUFFER</td>
<td>Use the <code>SET_RECORD_BUFFER</code> function for compatibility with HP NonStop user exits, and for complex data record manipulation.</td>
</tr>
<tr>
<td>SET_SESSION_CHARSET</td>
<td>Use the <code>SET_SESSION_CHARSET</code> function to set the character set of the user exit session.</td>
</tr>
<tr>
<td>SET_TABLE_NAME</td>
<td>Use the <code>SET_TABLE_NAME</code> function to change the table name associated with a data record.</td>
</tr>
</tbody>
</table>
COMPRESS_RECORD

Valid For

Extract and Replicat

Description

Use the COMPRESS_RECORD function to re-compress records that have been decompressed with the DECOMPRESS_RECORD function. Call COMPRESS_RECORD only after using DECOMPRESS_RECORD.

The content of the record buffer is not converted to or from the character set of the user exit. It is passed as-is.

Syntax

```c
#include "usrdecs.h"
short result_code;
compressed_rec_def compressed_rec;
ERCALLBACK (COMPRESS_RECORD, &compressed_rec, &result_code);
```

Buffer

```c
typedef struct
{
  char *compressed_rec;
  long compressed_len;
  char *decompressed_rec;
  long decompressed_len;
  short *columns_present;
  short source_or_target;
  char requesting_before_after_ind;
} compressed_rec_def;
```

Input

`decompressed_rec`
A pointer to the buffer containing the record before compression. The record is assumed to be in the default Oracle GoldenGate canonical format.

`decompressed_len`
The length of the decompressed record.

`source_or_target`
One of the following to indicate whether the source or target record is being compressed.

- `EXIT_FN_SOURCE_VAL`
- `EXIT_FN_TARGET_VAL`

`requesting_before_after_ind`
Used as internal input. Does not need to be set. If set, it will be ignored.

`columns_present`
An array of values that indicates the columns present in the compressed record. For example, if the first, third and sixth columns exist in the compressed record, and the total number of columns in the table is seven, the array should contain:
Use the GET_TABLE_COLUMN_COUNT function to get the number of columns in the table (see "GET_TABLE_COLUMN_COUNT" on page 6-71).

Output

compressed_rec
A pointer to the record returned in compressed format. Typically, compressed_rec is a pointer to a buffer of type exit_rec_buf_def. The exit_rec_buf_def buffer contains the actual record about to be processed by Extract or Replicat. The buffer is supplied when the call type is EXIT_CALL_DISCARD_RECORD. Exit routines may change the contents of this buffer, for example to perform custom mapping functions. The caller must ensure that the appropriate amount of memory is allocated to compressed_rec.

compressed_len
The returned length of the compressed record.

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
EXIT_FN_RET_INVALID_PARAM
DECOMPRESS_RECORD

Valid For

Extract and Replicat

Description

Use the DECOMPRESS_RECORD function when you want to retrieve or manipulate an entire update record with the GET_RECORD_BUFFER (see "GET_RECORD_BUFFER" on page 6-59) or SET_RECORD_BUFFER function (see "SET_RECORD_BUFFER" on page 6-94) and the record is compressed. DECOMPRESS_RECORD makes compressed records easier to process and map by putting the record into its logical column layout. The columns that are present will be in the expected positions without the index and length indicators (see "Compressed Record Format"). The missing columns will be represented as zeroes. When used, DECOMPRESS_RECORD should be invoked before any manipulation occurs. After the user exit processing is completed, use the COMPRESS_RECORD function (see "COMPRESS_RECORD" on page 6-8) to re-compress the record before returning it to the Oracle GoldenGate process.

This function is valid for processing UPDATE operations only. Deletes, inserts and updates appear in the buffer as full record images.

The content of the record buffer is not converted to or from the character set of the user exit. It is passed as-is.

Compressed Record Format

Compressed SQL updates have the following format:

\[\text{index length value [index length value ]} [...]\]

where:

- **index** is a two-byte index into the list of columns of the table (first column is zero).
- **length** is the two-byte length of the table.
- **value** is the actual column value, including one of the following two-byte null indicators when applicable. 0 is not null. -1 is null.

Syntax

```c
#include "usrdecs.h"
short result_code;
compressed_rec_def compressed_rec;
ERCALLBACK (DECOMPRESS_RECORD, &compressed_rec, &result_code);
```

Buffer

```c
typedef struct
{
    char *compressed_rec;
    long compressed_len;
    char *decompressed_rec;
    long decompressed_len;
    short *columns_present;
    short source_or_target;
    char requesting_before_after_ind;
} compressed_rec_def;
```
DECOMPRESS_RECORD

) compressed_rec_def;

---

### Input

**compressed_rec**
A pointer to the record in compressed format. Use the GET_RECORD_BUFFER function to obtain this value (see "GET_RECORD_BUFFER" on page 6-59).

**compressed_len**
The length of the compressed record. Use the GET_RECORD_BUFFER (see "GET_RECORD_BUFFER" on page 6-59) or GET_RECORD_LENGTH (see "GET_RECORD_LENGTH" on page 6-62) function to get this value.

**source_or_target**
One of the following to indicate whether the source or target record is being decompressed.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

**requesting_before_after_ind**
Used as internal input. Does not need to be set. If set, it will be ignored.

---

### Output

**decompressed_rec**
A pointer to the record returned in decompressed format. The record is assumed to be in the Oracle GoldenGate internal canonical format. The caller must ensure that the appropriate amount of memory is allocated to decompressed_rec.

**decompressed_len**
The returned length of the decompressed record.

**columns_present**
An array of values that indicate the columns present in the compressed record. For example, if the first, third and sixth columns exist in the compressed record, and the total number of columns in the table is seven, the array should contain:

1, 0, 1, 0, 0, 1, 0

This array helps mapping functions determine when and whether a compressed column should be mapped.

---

### Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
EXIT_FN_RET_INVALID_PARAM
GET_BASE_OBJECT_NAME

Valid For

Extract and Replicat

Description

Use the `GET_BASE_OBJECT_NAME` function to retrieve the fully qualified name of the base object of a source or target object that is associated with the record being processed. This function is valid tables and other objects in a DDL operation.

To return only part of the base object name, see the following:

- `GET_BASE_OBJECT_NAME_ONLY`
- `GET_BASE_SCHEMA_NAME_ONLY`

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax

```c
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_BASE_OBJECT_NAME, &env_value, &result_code);
```

Buffer

```c
typedef struct {
    char *buffer;
    long max_length;
    long actual_length;
    short value_truncated;
    short index;
    short source_or_target;
} env_value_def;
```

Input

- **buffer**
  A pointer to a buffer to accept the returned object name. The name is null-terminated.

- **max_length**
  The maximum length of your allocated buffer to accept the object name. This is returned as a NULL terminated string.

- **source_or_target**
  One of the following indicating whether to return the source or target object name.

  - `EXIT_FN_SOURCE_VAL`
  - `EXIT_FN_TARGET_VAL`
Output

buffer
The fully qualified, null-terminated object name, for example `schema.object` or `catalog.schema.object`, depending on the database platform.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the object name is interpreted in the session character set.

actual length
The string length of the returned object name. The actual length does not include the null terminator. The actual length is 0 if the object is a table.

value_truncated
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the object name plus the null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
**GET_BASE_OBJECT_NAME_ONLY**

**Valid For**

Extract and Replicat

**Description**

Use the `GET_BASE_OBJECT_NAME_ONLY` function to retrieve the unqualified name (without the catalog, container, or schema) of the base object of a source or target object that is associated with the record that is being processed. This function is valid for tables and other objects in a DDL operation.

To return the fully qualified name of a base object, see the following:

`GET_OBJECT_NAME`

To return only the schema of the base object, see the following:

`GET_BASE_SCHEMA_NAME_ONLY`

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

**Syntax**

```c
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_BASE_OBJECT_NAME_ONLY, &env_value, &result_code);
```

**Buffer**

```c
typedef struct
{
  char *buffer;
  long max_length;
  long actual_length;
  short value_truncated;
  short index;
  short source_or_target;
} env_value_def;
```

**Input**

- **buffer**
  A pointer to a buffer to accept the returned object name. The name is null-terminated.

- **max_length**
  The maximum length of your allocated buffer to accept the object name. This is returned as a NULL terminated string.

- **source_or_target**
  One of the following indicating whether to return the source or target object name.

  - `EXIT_FN_SOURCE_VAL`
  - `EXIT_FN_TARGET_VAL`
Output

buffer
The fully qualified, null-terminated object name, for example schema.object or catalog.schema.object, depending on the database platform.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the object name is interpreted in the session character set.

actual length
The string length of the returned object name. The actual length does not include the null terminator. The actual length is 0 if the object is a table.

value_truncated
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the object name plus the null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_BASE_SCHEMA_NAME_ONLY

Description
Use the GET_BASE_SCHEMA_NAME_ONLY function to retrieve the name of the owner (such as schema), but not the name, of the base object of the source or target object associated with the record being processed. This function is valid for DDL operations.

To return the fully qualified name of a base object, see the following:
GET_BASE_OBJECT_NAME

To return only the unqualified base object name, see the following:
GET_BASE_OBJECT_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_BASE_SCHEMA_NAME_ONLY, &env_value, &result_code);

Buffer
typedef struct
{
  char *buffer;
  long max_length;
  long actual_length;
  short value_truncated;
  short index;
  short source_or_target;
} env_value_def;

Input

buffer
A pointer to a buffer to accept the returned schema name. The name is null-terminated.

max_length
The maximum length of your allocated buffer to accept the schema name. This is returned as a NULL terminated string.

source_or_target
One of the following indicating whether to return the source or target schema name.
EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

buffer
The fully qualified, null-terminated schema name.
If the character session of the user exit is set with \texttt{SET\_SESSION\_CHARSET} to a value other than the default character set of the operating system, as defined in \texttt{ULIB\_CS\_DEFAULT} in the \texttt{ucharset.h} file, the schema name is interpreted in the session character set.

\textbf{actual\_length}

The string length of the returned name. The actual length does not include the null terminator.

\textbf{value\_truncated}

A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the schema name plus the null terminator exceeds the maximum buffer length.

\textbf{Return Values}

- \texttt{EXIT\_FN\_RET\_INVALID\_COLUMN}
- \texttt{EXIT\_FN\_RET\_INVALID\_CONTEXT}
- \texttt{EXIT\_FN\_RET\_INVALID\_PARAM}
- \texttt{EXIT\_FN\_RET\_OK}
GET BEFORE AFTER IND

Valid For
Extract and Replicat

Description
Use the GET BEFORE AFTER IND function to determine whether a record is a before image or an after image of the database operation. INSERTs are after images, DELETEs are before images, and UPDATEs can be either before or after images (see the Extract and Replicat parameters GETUPDATEBEFORES and GETUPDATEAFTERS). If the before images of UPDATE operations are being extracted, the before images precede the after images within the same update.

Syntax
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_BEFORE_AFTER_IND, &record, &result_code);

Buffer
typedef struct
{
  char *table_name;
  char *buffer;
  long length;
  char before_after_ind;
  short io_type;
  short record_type;
  short transaction_ind;
  int64_t timestamp;
  exit_ts_str io_datetime;
  short mapped;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  char requesting_before_after_ind;
} record_def;

Input
None

Output
before_after_ind
One of the following to indicate whether the record is a before or after image.
BEFORE_IMAGE_VAL
AFTER_IMAGE_VAL

Return Values
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
GET_CATALOG_NAME_ONLY

Valid For

Extract and Replicat

Description

Use the GET_CATALOG_NAME_ONLY function to retrieve the name of the SQL/MX catalog or Oracle CDB container, but not the name of the owner (such as schema) or object, of the source or target object associated with the record being processed. This function is valid for DML and DDL operations.

To return the fully qualified name of a table, see the following:

GET_TABLE_NAME

To return the fully qualified name of a non-table object, such as a user, view or index, see the following:

GET_OBJECT_NAME

To return only the unqualified table or object name, see the following:

GET_TABLE_NAME_ONLY
GET_OBJECT_NAME_ONLY

To return other parts of the table or object name, see the following:

GET_SCHEMA_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax

```
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_CATALOG_NAME_ONLY, &env_value, &result_code);
```

Buffer

```
typedef struct
{
    char *buffer;
    long max_length;
    long actual_length;
    short value_truncated;
    short index;
    short source_or_target;
} env_value_def;
```

Input

**buffer**

A pointer to a buffer to accept the returned catalog name. The name is null-terminated.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_
DEFAULT in the ucharset.h file, the catalog name is interpreted in the session character set.

**max_length**
The maximum length of your allocated buffer to accept the name. This is returned as a NULL terminated string.

**source_or_target**
One of the following indicating whether to return the source or target table catalog.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

### Output

**buffer**
The fully qualified, null-terminated catalog name.

**actual_length**
The string length of the returned name. The actual length does not include the null terminator.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the catalog name plus the null terminator exceeds the maximum buffer length.

### Return Values

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_COL_METADATA_FROM_INDEX

Valid For
Extract and Replicat

Description
Use the GET_COL_METADATA_FROM_INDEX function to retrieve column metadata by specifying the index of the desired column.

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax
#include "usrdecs.h"
short result_code;
col_metadata_def column_meta_rec;
ERCALLBACK (GET_COL_METADATA_FROM_INDEX, &column_meta_rec, &result_code);

Buffer
typedef struct
{
    short column_index;
    char *column_name;
    long max_name_length;
    short native_data_type;
    short gg_data_type;
    short gg_sub_data_type;
    short is_nullable;
    short is_part_of_key;
    short key_column_index;
    short length;
    short precision;
    short scale;
    short source_or_target;
} col_metadata_def;

Input
column_index
The column index of the column value to be returned.

max_name_length
The maximum length of the returned column name. Typically, the maximum length is the length of the name buffer. Since the returned name is null-terminated, the maximum length should equal the maximum length of the column name.

source_or_target
One of the following to indicate whether the source or target record is being compressed.
EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
Output

column_name
The column name of the column value to be returned.

actual_name_length
The actual length of the returned name.

value_truncated
A flag (0 or 1) to indicate whether or not the value was truncated. Truncation occurs if
the length of the column name plus the null terminator exceeds the maximum buffer
length.

native_data_type
The native (to the database) data type of the column. Either native_data_type or dd_
data_type is returned, depending on the process, as follows:

■ If Extract is making the callback request for a source column, native_data_type is
  returned. If Extract is requesting a mapped target column, gg_data_type is
  returned (assuming there is a target definitions file on the system).

■ If an Extract data pump is making the callback request for a source column and
  there is a local database, native_data_type is returned. If there is no database, gg_
data_type is returned (assuming there is a source definitions file on the system). If
  the pump is requesting the target column, gg_data_type is returned (assuming a
  target definitions file exists on the system).

■ If Replicat is making the callback request for the source column, then gg_data_
type is returned (assuming a source definitions file exists on the system). If
  Replicat is requesting the source column and ASSUMETARGETDEFS is being used in
  the parameter file, then native_data_type is returned. If Replicat is requesting the
target column, native_data_type is returned.

gg_data_type
The Oracle GoldenGate data type of the column.

gg_sub_data_type
The Oracle GoldenGate sub-type of the column.

is_nullable
Flag indicating whether the column permits a null value (TRUE or FALSE).

is_part_of_key
Flag (TRUE or FALSE) indicating whether the column is part of the key that is being
used by Oracle GoldenGate.

key_column_index
Indicates the order of the columns in the index. For example, the following table has
two key columns that exist in a different order from the order in which they are
declared in the primary key.

CREATE TABLE ABC
(
cust_code VARCHAR2(4),
name VARCHAR2(30),
city VARCHAR2(20),
state CHAR(2),
PRIMARY KEY (city, cust_code)
USING INDEX
Executing the callback function for each column in the logical column order returns the following:

- `cust_code` returns 1
- `name` returns -1
- `city` returns 0
- `state` returns -1

If the column is part of the key, the value returned is the order of the column within the key.

If the column is not part of the key, a value of -1 is returned.

**length**

Returns the length of the column.

**precision**

If a numeric data type, returns the precision of the column.

**scale**

If a numeric data type, returns the scale.

### Return Values

- `EXIT_FN_RET_INVALID_PARAM`
- `EXIT_FN_RET_INVALID_CONTEXT`
- `EXIT_FN_RET_EXCEEDED_MAX_LENGTH`
- `EXIT_FN_RET_INVALID_COLUMN`
- `EXIT_FN_RET_OK`
GET_COL_METADATA_FROM_NAME

Valid For

Extract and Replicat

Description

Use the GET_COL_METADATA_FROM_NAME function to retrieve column metadata by specifying the name of the desired column. If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter.

Syntax

#include "usrdecs.h"
short result_code;
col_metadata_def column_meta_rec;
ERCALLBACK (GET_COL_METADATA_FROM_NAME, &column_meta_rec, &result_code);

Buffer

typedef struct
{
  short column_index;
  char *column_name;
  long max_name_length;
  short native_data_type;
  short gg_data_type;
  short gg_sub_data_type;
  short is_nullable;
  short is_part_of_key;
  short key_column_index;
  short length;
  short precision;
  short scale;
  short source_or_target;
} col_metadata_def;

Input

column_name
The column name of the column value to be returned.

max_name_length
The maximum length of the returned column name. Typically, the maximum length is the length of the name buffer. Since the returned name is null-terminated, the maximum length should equal the maximum length of the column name.
source_or_target
One of the following to indicate whether the source or target record is being compressed.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

column_index
The column index of the column value to be returned.

actual_name_length
The actual length of the returned name.

source_or_target
One of the following to indicate whether the source or target record is being compressed.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

value_truncated
A flag (0 or 1) to indicate whether or not the value was truncated. Truncation occurs if the length of the column name plus the null terminator exceeds the maximum buffer length.

native_data_type
The native (to the database) data type of the column.

gg_data_type
The Oracle GoldenGate data type of the column.

gg_sub_data_type
The Oracle GoldenGate sub-type of the column.

is_nullable
Flag indicating whether the column permits a null value (TRUE or FALSE).

is_part_of_key
Flag (TRUE or FALSE) indicating whether the column is part of the key that is being used by Oracle GoldenGate.

key_column_index
Indicates the order of the columns in the index. For example, the following table has two key columns that are defined in one order in the table and another in the index definition.

```
CREATE TABLE tcustmer
(
cust_code        VARCHAR2(4),
name             VARCHAR2(30),
city             VARCHAR2(20),
state            CHAR(2),
PRIMARY KEY (city, cust_code)
USING INDEX
);
```

The return is as follows:
- cust_code returns 1
- name returns -1
- city returns 0
- state returns -1

If the column is part of the key, its order in the index is returned as an integer.
If the column is not part of the key, a value of -1 is returned.

**length**
Returns the length of the column.

**precision**
If a numeric data type, returns the precision of the column.

**scale**
If a numeric data type, returns the scale.

**Return Values**

- EXIT_FN_RET_INVALID_PARAM
- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_EXCEED_MAX_LENGTH
- EXIT_FN_RET_INVALID_COLUMN
- EXIT_FN_RET_OK
GET_COLUMN_INDEX_FROM_NAME

Valid For
Extract and Replicat

Description
Use the GET_COLUMN_INDEX_FROM_NAME function to determine the column index associated with a specified column name. If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter.

Syntax
```
#include 'usrdecs.h'
short result_code;
env_value_def env_value;
ERCALLBACK (GET_COLUMN_INDEX_FROM_NAME, &env_value, &result_code);
```

Buffer
typedef struct
{
  char *buffer;
  long max_length;
  long actual_length;
  short value_truncated;
  short index;
  short source_or_target;
} env_value_def;

Input

buffer
A pointer to the column name

actual_length
The length of the column name within the buffer.

source_or_target
One of the following to indicate whether to use the source or target table to look up column information.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

index
The returned column index for the specified column name.
Return Values

- EXIT_FN_RET_INVALID_COLUMN
- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_INVALID_PARAM
- EXIT_FN_RET_OK
GET_COLUMN_NAME_FROM_INDEX

Valid For
Extract and Replicat

Description
Use the \texttt{GET\_COLUMN\_NAME\_FROM\_INDEX} function to determine the column name associated with a specified column index. If the character session of the user exit is set with \texttt{SET\_SESSION\_CHARSET} to a value other than the default character set of the operating system, as defined in \texttt{ULIB\_CS\_DEFAULT} in the \texttt{ucharset.h} file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax

\begin{verbatim}
#include 'usrdecs.h'
short result_code;
env_value_def env_value;
ERCALLBACK (GET_COLUMN_NAME_FROM_INDEX, &env_value, &result_code);
\end{verbatim}

Buffer

\texttt{typedef struct}
\begin{verbatim}
{
  char *buffer;
  long max_length;
  long actual_length;
  short value_truncated;
  short index;
  short source_or_target;
} env_value_def;
\end{verbatim}

Input

\textbf{buffer}
A pointer to a buffer to accept the returned column name. The column name is null-terminated.

\textbf{max_length}
The maximum length of your allocated \texttt{buffer} to accept the resulting column name. This is returned as a \texttt{NULL} terminated string.

\textbf{index}
The column index of the column name to be returned.

\textbf{source_or_target}
One of the following to indicate whether to use the source or target table to look up column information.

\texttt{EXIT\_FN\_SOURCE\_VAL}
\texttt{EXIT\_FN\_TARGET\_VAL}
GET_COLUMN_NAME_FROM_INDEX

Output

buffer
The null-terminated column name.

actual length
The string length of the returned column name. The actual length does not include the null terminator.

value truncated
A flag (0 or 1) to indicate whether or not the value was truncated. Truncation occurs if the length of the column name plus the null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_COLUMN_VALUE_FROM_INDEX

Valid For
Extract and Replicat

Description
Use the GET_COLUMN_VALUE_FROM_INDEX function to retrieve the column value from the data record using the specified column index. Column values are the basis for most logic within the user exit. You can base complex logic on the values of individual columns within the data record. You can specify the character format of the returned value.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

A column value is set to the session character set only if the following is true:

- The column value is a SQL character type (CHAR/VARCHAR2/CLOB, NCHAR/NVARCHAR2/NCLOB), a SQL date/timestamp/interval/number type
- The column_value_mode indicator is set to EXIT_FN_CNVTED_SESS_CHAR_FORMAT.

Syntax

```c
#include "usrdecs.h"
short result_code;
column_def column;
ERCALLBACK(GET_COLUMN_VALUE_FROM_INDEX, &column, &result_code);
```

Buffer

typedef struct
{
  char *column_value;
  unsigned short max_value_length;
  unsigned short actual_value_length;
  short null_value;
  short remove_column;
  short value_truncated;
  short column_index;
  char *column_name;
  /* Version 3 CALLBACK_STRUCT_VERSION */
  short column_value_mode;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  char requesting_before_after_ind;
  char more_lob_data;
  /* Version 3 CALLBACK_STRUCT_VERSION */
  ULibCharSet column_charset;
} column_def;
```
**Input**

`column_value`
A pointer to a buffer to accept the returned column value.

`max_value_length`
The maximum length of the returned column value. Typically, the maximum length is the length of the column value buffer. If ASCII format is specified with `column_value_mode`, the column value is null-terminated and the maximum length should equal the maximum length of the column value.

`column_index`
The column index of the column value to be returned.

`column_value_mode`
Indicates the format of the column value.

**EXIT_FN_CHAR_FORMAT**
ASCII format: The value is a null-terminated ASCII (or EBCDIC) string (with a known exception for the sub-data type `UTF16_BE`, which is converted to UTF8.)

**Note:** A column value might be truncated when presented to a user exit, because the value is interpreted as an ASCII string and is supposed to be null-terminated. The first value of 0 becomes the string terminator.

- Dates are in the format `CCYY-MM-DD HH:MI:SS.FFFFFF`, in which the fractional time is database-dependent.
- Numeric values are in their string format. For example, `123.45` is represented as `"123.45".`
- Non-printable characters or binary values are converted to hexadecimal notation.
- Floating point types are output as null-terminated strings, to the first 14 significant digits.

**EXIT_FN_RAW_FORMAT**
Internal Oracle GoldenGate canonical format: This format includes a two-byte NULL indicator and a two-byte variable data length when applicable. No character-set conversion is performed by Oracle GoldenGate for this format for any character data type.

**EXIT_FN_CNVTED_SESS_CHAR_FORMAT**
User exit character set: This only applies if the column data type is:
- a character-based type, single or multi-byte
- a numeric type with a string representation
This format is not null-terminated.

**source_or_target**
One of the following to indicate whether to use the source or the target data record to retrieve the column value.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
requesting_before_after_ind
Set when processing an after image record and you want the before-image column value of either an update or a primary key update.

To get the "before" value of the column while processing an "after image" of a primary key update or a regular (non-key) update record, set the requesting_before_after_ind flag to BEFORE_IMAGE_VAL.

- To access the before image of the key columns of a primary key update, nothing else is necessary.
- To access non-key columns of a primary key update or any column of a regular update, the before image must be available.

The default setting is AFTER_IMAGE_VAL (get the after image of the column) when an explicit input for requesting_before_after_ind is not specified.

To make a before image available, you can use the GETUPDATEBEFORES parameter or you can use the INCLUDEUPDATEBEFORES option within the CUSEREXIT parameter statement.

Note that:
- GETUPDATEBEFORES causes an Extract process to write before-image records to the trail and also to make an EXIT_CALL_PROCESS_RECORD call to the user exit with the before images.
- INCLUDEUPDATEBEFORES does not cause an EXIT_CALL_PROCESS_RECORD call to the user exit nor, in the case of Extract, does it cause the process to write the before image to the trail.

requesting_before_after_ind
To get the before image of the column, set the char requesting_before_after_ind flag to BEFORE_IMAGE_VAL. To get the after image, set it to AFTER_IMAGE_VAL. The default is to always work with the after image unless the before is specified.

To make the before images available, you can use the GETUPDATEBEFORES parameter for the TABLE statement that contains the table, or you can use the INCLUDEUPDATEBEFORES option within the CUSEREXIT parameter statement. Both will cause the same callout to the user exit for process_record.

Output

column_value
A pointer to the returned column value. If column_value_mode is specified as EXIT_FN_CHAR_FORMAT, the column value is returned as a null-terminated ASCII string; otherwise, the column value is returned in the Oracle GoldenGate internal canonical format. In ASCII format, dates are returned in the following format:

YYYY-MM-DD HH:MI:SS.FFFFFF

The inclusion of fractional time is database-dependent.

actual_value_length
The string length of the returned column name, in bytes. The actual length does not include a null terminator when column_value_mode is specified as EXIT_FN_CHAR_FORMAT.
null_value
A flag (0 or 1) indicating whether or not the column value is null. If the null_value flag is 1, then the column value buffer is filled with null bytes.

value_truncated
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the column value exceeds the maximum buffer length. If column_value_mode was specified as EXIT_FN_CHAR_FORMAT, the null terminator is included in the length of the column.

char more_lob_data
A flag that indicates if more LOB data is present beyond the initial 4K that can be stored in the base record. When a LOB is larger than the 4K limit, it is stored in LOB fragments.

You must allocate the appropriate amount of memory to contain the returned values. Oracle GoldenGate will access LOB columns up to 8K of data at all times, filling up the buffer to the amount that the user exit has allocated. If the LOB is larger than that which was allocated, subsequent callbacks are required to obtain the total column data, until all data has been sent to the user exit.

To determine the end of the data, evaluate more_lob_data. The user exit sets this flag to either CHAR_NO_VAL or CHAR_YES_VAL before accessing a new column. If this flag is still initialized after first callback and is not set to either CHAR_YES_VAL or CHAR_NO_VAL, then one of the following is true:

- Enough memory was allocated to handle the LOB.
- It is not a LOB.
- It was not over the 4K limit of the base trail record size.

It is recommended that you obtain the source table metadata to determine if a column might be a LOB.

Return Values

EXIT_FN_RET_BAD_COLUMN_DATA
EXIT_FN_RET_COLUMN_NOT_FOUND
EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_COLUMN_VALUE_FROM_NAME

Valid For
Extract and Replicat

Description
Use the GET_COLUMN_VALUE_FROM_NAME function to retrieve the column value from the data record by using the specified column name. Column values are the basis for most logic within the user exit. You can base complex logic on the values of individual columns within the data record.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

A column value is set to the session character set only if the following is true:

- The column value is a SQL character type (CHAR/VARCHAR2/CLOB, NCHAR/NVARCHAR2/NCLOB), a SQL date/timestamp/interval/number type
- The column_value_mode indicator is set to EXIT_FN_CNVTED_SESS_CHAR_FORMAT.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter.

Syntax

```
#include 'usrdecs.h'
short result_code;
column_def column;
ERCALLBACK (GET_COLUMN_VALUE_FROM_NAME, &column, &result_code);
```

Buffer

```
typedef struct
{
    char *column_value;
    unsigned short max_value_length;
    unsigned short actual_value_length;
    short null_value;
    short remove_column;
    short value_truncated;
    short column_index;
    char *column_name;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    short column_value_mode;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
    char more_lob_data;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    ULibCharSet column_charset;
} column_def;
```
Input

column_value
A pointer to a buffer to accept the returned column value.

max_value_length
The maximum length of the returned column value. Typically, the maximum length is the length of the column value buffer. If ASCII format is specified (see column_value_mode) the column value is null-terminated, and the maximum length should equal the maximum length of the column value.

column_name
The name of the column for the column value to be returned.

column_value_mode
Indicates the character set of the column value.

EXIT_FN_CHAR_FORMAT
ASCII format: The value is a null-terminated ASCII (or EBCDIC) string (with a known exception for the sub-data type UTF16_BE, which is converted to UTF8.)

Note: A column value might be truncated when presented to a user exit, because the value is interpreted as an ASCII string and is supposed to be null-terminated. The first value of 0 becomes the string terminator.

- Dates are in the format CCYY-MM-DD HH:MI:SS.FFFFFF, in which the fractional time is database-dependent.
- Numeric values are in their string format. For example, 123.45 is represented as "123.45".
- Non-printable characters or binary values are converted to hexadecimal notation.
- Floating point types are output as null-terminated strings, to the first 14 significant digits.

EXIT_FN_RAW_FORMAT
Internal Oracle GoldenGate canonical format: This format includes a two-byte null indicator and a two-byte variable data length when applicable. No character-set conversion is performed by Oracle GoldenGate for this format for any character data type.

EXIT_FN_CNVTED_SESS_CHAR_FORMAT
User exit character set: This only applies if the column data type is:
- a character-based type, single or multi-byte
- a numeric type with a string representation
This format is not null-terminated.

source_or_target
One of the following indicating whether to use the source or target data record to retrieve the column value.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
**requesting_before_after_ind**

Set when processing an after image record and you want the before columns of either an update or a primary key update.

To get the "before" value of the column while processing an "after image" of a primary key update or a regular (non-key) update record, set the `requesting_before_after_ind` flag to `BEFORE_IMAGE_VAL`.

- To access the before image of the key columns of a primary key update, nothing else is necessary.
- To access non-key columns of a primary key update or any column of a regular update, the before image must be available.

The default setting is `AFTER_IMAGE_VAL` (get the after image of the column) when an explicit input for `requesting_before_after_ind` is not specified.

To make a before image available, you can use the `GETUPDATEBEFORES` parameter or you can use the `INCLUDEUPDATEBEFORES` option within the `USEREXIT` parameter statement.

Note that:

- `GETUPDATEBEFORES` causes an Extract process to write before-image records to the trail and also to make an `EXIT_CALL_PROCESS_RECORD` call to the user exit with the before images.
- `INCLUDEUPDATEBEFORES` does not cause an `EXIT_CALL_PROCESS_RECORD` call to the user exit nor, in the case of Extract, does it cause the process to write the before image to the trail.

**Output**

**column_value**

A pointer to the returned column value. If `column_value_mode` is specified as `EXIT_FN_CHAR_FORMAT`, the column value is returned as a null-terminated ASCII string; otherwise, the column value is returned in the Oracle GoldenGate internal canonical format. In ASCII format, dates are returned in the following format:

```
CCYY-MM-DD HH:MI:SS.FFFFFF
```

The inclusion of fractional time is database-dependent.

**actual length**

The string length of the returned column name. The actual length does not include a null terminator when `column_value_mode` is specified as `EXIT_FN_CHAR_FORMAT`.

**null_value**

A flag (0 or 1) indicating whether or not the column value is null. If the `null_value` flag is 1, then the column value buffer is filled with null bytes.

**value_truncated**

A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the column value exceeds the maximum buffer length. If `column_value_mode` was specified as `EXIT_FN_CHAR_FORMAT`, the null terminator is included in the length of the column.
char more_lob_data
A flag that indicates if more LOB data is present beyond the initial 4K that can be stored in the base record. When a LOB is larger than the 4K limit, it is stored in LOB fragments.

You must allocate the appropriate amount of memory to contain the returned values. Oracle GoldenGate will access LOB columns up to 8K of data at all times, filling up the buffer to the amount that the user exit has allocated. If the LOB is larger than that which was allocated, subsequent callbacks are required to obtain the total column data, until all data has been sent to the user exit.

To determine the end of the data, evaluate more_lob_data. The user exit sets this flag to either CAR_NO_VAL or CHAR_YES_VAL before accessing a new column. If this flag is still initialized after first callback and is not set to either CHAR_YES_VAL or CAR_NO_VAL, then one of the following is true:

- Enough memory was allocated to handle the LOB.
- It is not a LOB.
- It was not over the 4K limit of the base trail record size.

It is recommended that you obtain the source table metadata to determine if a column might be a LOB.

Return Values
EXIT_FN_RET_BAD_COLUMN_DATA
EXIT_FN_RET_COLUMN_NOT_FOUND
EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK

Example
memset (&col_meta, 0, sizeof(col_meta));
if (record.mapped)
col_meta.source_or_target = EXIT_FN_TARGET_VAL;
else
col_meta.source_or_target = EXIT_FN_SOURCE_VAL;
col_meta.source_or_target = EXIT_FN_SOURCE_VAL;
col_meta.column_name = (char *)malloc(100);
col_meta.max_name_length = 100;
col_meta.column_index = 1;
call_callback (GET_COL_METADATA_FROM_NAME, &col_meta, &result_code);
GET_DATABASE_METADATA

Valid For

Extract and Replicat

Description

Use the GET_DATABASE_METADATA function to return the metadata of the database that is associated with a record.

Buffer

typedef struct
{
   char*    dbName;
   long      dbName_max_length;
   long      dbName_actual_length;
   unsigned char    dbNameMetadata[MAXDBOBJTYPE];
   char*   locale;
   long     locale_max_length;
   long     locale_actual_length;
} database_def;
typedef struct
{
   database_def  source_db_def;
   database_def  target_db_def;
} database_defs;

Input

dbname
A pointer to a buffer to accept the database name.

dbname_max_length
The maximum length of the buffer to hold the name.

dbname_actual_length
The actual length of the database name.

dbNameMetadata
The name metadata for case-sensitivity, which is the same value that is written by Extract and the data pump to a trail. See Administering Oracle GoldenGate for Windows and UNIX for a list of macros that can be used by the user exit to check database object name metadata, given an object name type.

locale
A null-terminated character string specifying the locale of the database. This is returned as a conjunction of:
- ISO-639 two-letter language code
- ISO-3166 two-letter country code
- Variant code using '_' U+005F as separator.
Example: "en_US", "ja_Japen"
locale_max_length
The maximum length of the buffer to accept the locale.

locale_actual_length
The actual length of the locale.

database_def source_db_def
Directs the process to return metadata for the source database.

database_def target_db_def
Directs the process to return metadata for the target database.
GET_DDL_RECORD_PROPERTIES

Valid For

Extract and Replicat, for databases for which DDL replication is supported

Description

Use the GET_DDL_RECORD_PROPERTIES function to return a DDL operation, including information about the object on which the DDL was performed and also the text of the DDL statement itself. The Extract process can only get the source table layout. The Replicat process can get source or target layouts.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set. This includes the DDL type, the object type, the two- or three-part object name, the owner name and the DDL text itself.

```c
#include "usrdecs.h"
short result_code;
ddl_record_def ddl_rec;
ERCALLBACK (GET_DDL_RECORD_PROPERTIES, &ddl_rec, &result_code);
```

Buffer

typedef struct
{
    char *ddl_type;
    long ddl_type_max_length; /* Maximum Description length PASSED IN BY USER */
    long ddl_type_length; /* Actual length */

    char *object_type;
    long object_type_max_length; /* Maximum Description length PASSED IN BY USER */
    long object_type_length; /* Actual length */

    char *object_name; /* Fully qualified name of the object
    (3-part for CDB, 2-part for non-CDB) */
    long object_max_length; /* Maximum Description length PASSED IN BY USER */
    long object_length; /* Actual length */

    char *owner_name;
    long owner_max_length; /* Maximum Description length PASSED IN BY USER */
    long owner_length; /* Actual length */

    char *ddl_text;
    long ddl_text_max_length; /* Maximum Description length PASSED IN BY USER */
    long ddl_text_length; /* Actual length */

    short ddl_text_truncated; /* Was value truncated? */
    short source_or_target; /* Source or target value */
} ddl_record_def;

Input

ddl_type_length
object_type_length
object_length
owner_length
ddl_text_length
A pointer to one buffer for each of these items to accept the returned column values. These items are as follows:

ddl_type_length
Contains the length of the type of DDL operation, for example a CREATE or ALTER.

object_type_length
Contains the length of type of database object that is affected by the DDL operation, for example TABLE or INDEX.

object_length
Contains the length of the name of the object.

owner_length
Contains the length of the owner of the object (schema or database).

ddl_text_length
Contains the length of the actual DDL statement text.

ddl_type_max_length
The maximum length of the DDL operation type that is returned by *ddl_type. The DDL type is any DDL command that is valid for the database, such as ALTER.

object_type_max_length
The maximum length of the object type that is returned by *object_type. The object type is any object that is valid for the database, such as TABLE, INDEX, and TRIGGER.

object_max_length
The maximum length of the name of the object that is returned by *object_name.

owner_max_length
The maximum length of the name of the owner that is returned by *owner_name.

ddl_text_max_length
The maximum length of the text of the DDL statement that is returned by *ddl_text.

source_or_target
One of the following indicating whether to return the operation type for the source or the target data record.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
Output

- **ddl_type_length**
- **object_type_length**
- **object_length**
- **owner_length**
- **ddl_text_length**
  All of these fields return the actual length of the value that was requested. (See the input for descriptions.)

- **ddl_text_truncated**
  A flag (0 or 1) to indicate whether or not the DDL text was truncated. Truncation occurs if the length of the DDL text plus the null terminator exceeds the maximum buffer length.

Return Values

- **EXIT_FN_RET_OK**
- **EXIT_FN_RET_NOT_SUPPORTED**
- **EXIT_FN_RET_INVALID_CONTEXT**
- **EXIT_FN_RET_INCOMPLETE_DDL_REC**
GET_ENV_VALUE

Valid For
Extract and Replicat

Description
Use the GET_ENV_VALUE function to return information about the Oracle GoldenGate environment. The information that is supplied is the same as that of the @GETENV column-conversion function and is specified by using the same input values. For more information about the valid information types, environment variables, and return values, see "GETENV" on page 5-20.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

Syntax
#include "usrdecs.h"
short result_code;
getenv_value_def env_ptr;
ERCALLBACK (GET_ENV_VALUE, &env_ptr, &result_code);

Buffer
typedef struct
{
    char *information_type;
    char *env_value_name;
    char *return_value;
    long max_return_length;
    long actual_length;
    short value_truncated;
} getenv_value_def;

Input

information_type
The information type that is to be returned, for example 'GGENVIRONMENT' or 'GGHEADER'. The information type must be supplied within double quotes. For a list of information types and subsequent detailed descriptions, see "GETENV" on page 5-20.

env_value_name
The environment value that is wanted from the information type. The environment value must be supplied within double quotes. For valid values, see "GETENV" on page 5-20. For example, if using the 'GGENVIRONMENT' information type, a valid environment value would be 'GROUPNAME'.

max_return_length
The maximum length of the buffer for this data.
Output

**return_value**
A valid return value for the supplied environment value.

**actual_length**
The actual length of the data in this buffer.

**value_truncated**
A flag (0 or 1) to indicate whether or not the value was truncated. Truncation occurs if the length of the value plus the null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_OK
EXIT_FN_RET_ENV_NOT_FOUND
EXIT_FN_RET_INVALID_PARAM
GET_ERROR_INFO

Valid For
Extract and Replicat

Description
Use the GET_ERROR_INFO function to retrieve error information associated with a discard record. The user exit can use this information in custom error handling logic. For example, the user exit could send an e-mail message with detailed error information.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the message data that is exchanged between the user exit and the process is interpreted in the session character set.

Syntax
```
#include "usrdecs.h"
short result_code;
error_info_def error_info;
ERCALLBACK(GET_ERROR_INFO, &error_info, &result_code);
```

Buffer
typedef struct
{
    long error_num;
    char *error_msg;
    long max_length;
    long actual_length;
    short msg_truncated;
} error_info_def;

Input

error_msg
A pointer to a buffer to accept the returned error message.

max_length
The maximum length of your allocated error_msg buffer to accept any resulting error message. This is returned as a NULL terminated string.

Output

error_num
The SQL or system error number associated with the discarded record.

error_msg
A pointer to the null-terminated error message string associated with the discarded record.

actual_length
The length of the error message, not including the null terminator.
msg_truncated
A flag (0 or 1) indicating whether or not the error message was truncated. Truncation occurs if the length of the error message plus a null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
GET_GMT_TIMESTAMP

Valid For
Extract and Replicat

Description
Use the GET_GMT_TIMESTAMP function to retrieve the operation commit timestamp in GMT format. This function requires compiling with Version 2 usrdecs.h or later.

Syntax
```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_GMT_TIMESTAMP, &record, &result_code);
```

Buffer
```c
typedef struct
{
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;
```

Input
None

Output

- **timestamp**
The returned 64-bit I/O timestamp in GMT format.

- **io_datetime**
A null-terminated string containing the local I/O date and time:

  YYYY-MM-DD HH:MI:SS.FFFFFF

  The format of the datetime string is in the session character set.

Return Values

- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_OK
GET_MARKER_INFO

Valid For

Extract (data pump only) and Replicat

Description

Use the GET_MARKER_INFO function to retrieve marker information sent from a NonStop source system when Replicat is applying data. Use markers to trigger custom processing within a user exit.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, all of the returned marker data is interpreted in the session character set.

Syntax

```c
#include "usrdecs.h"
short result_code;
marker_info_def marker_info;
ERCALLBACK (GET_MARKER_INFO, &marker_info, &result_code);
```

Buffer

```c
typedef struct
{
    char *processed;
    char *added;
    char *text;
    char *group;
    char *program;
    char *node;
} marker_info_def;
```

Input

`processed`
A pointer to a buffer to accept the processed return value.

`added`
A pointer to a buffer to accept the added return value.

`text`
A pointer to a buffer to accept the text return value.

`group`
A pointer to a buffer to accept the group return value.

`program`
A pointer to a buffer to accept the program return value.

`node`
A pointer to a buffer to accept the node return value.
Output

processed
A null-terminated string in the format of YYYY-MM-DD HH:MI:SS indicating the local date and time that the marker was processed.

added
A null-terminated string in the format of YYYY-MM-DD HH:MI:SS indicating the local date and time that the marker was added.

text
A null-terminated string containing the text associated with the marker.

group
A null-terminated string indicating the Replicat group that processed the marker.

program
A null-terminated string indicating the program that processed the marker.

node
A null-terminated string representing the Himalaya node on which the marker was originated.

Return Values
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
GET_OBJECT_NAME

Valid For

Extract and Replicat

Description

Use the GET_OBJECT_NAME function to retrieve the fully qualified name of a source or target object that is associated with the record being processed. This function is valid for tables and other objects in a DML or DDL operation.

To return only part of the object name, see the following:

GET_OBJECT_NAME_ONLY
GET_SCHEMA_NAME_ONLY
GET_CATALOG_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax

```c
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_OBJECT_NAME, &env_value, &result_code);
```

Buffer

```c
typedef struct
{
char *buffer;
long max_length;
long actual_length;
short value_truncated;
short index;
short source_or_target;
} env_value_def;
```

Input

**buffer**
A pointer to a buffer to accept the returned object name. The name is null-terminated.

**max_length**
The maximum length of your allocated buffer to accept the object name. This is returned as a NULL terminated string.

**source_or_target**
One of the following indicating whether to return the source or target object name.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
Output

**buffer**
The fully qualified, null-terminated object name, for example `schema.object` or `catalog.schema.object`, depending on the database platform.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the object name is interpreted in the session character set.

**actual length**
The string length of the returned object name. The actual length does not include the null terminator. The actual length is 0 if the object is a table.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the object name plus the null terminator exceeds the maximum buffer length.

Return Values

- `EXIT_FN_RET_INVALID_COLUMN`
- `EXIT_FN_RET_INVALID_CONTEXT`
- `EXIT_FN_RET_INVALID_PARAM`
- `EXIT_FN_RET_OK`
GET_OBJECT_NAME_ONLY

Valid For
Extract and Replicat

Description
Use the GET_OBJECT_NAME_ONLY function to retrieve the unqualified name (without the catalog, container, or schema) of a source or target object that is associated with the record that is being processed. This function is valid for tables and other objects in a DML or DDL operation.

To return the fully qualified name of an object, see the following:
GET_OBJECT_NAME

To return other parts of the object name, see the following:
GET_SCHEMA_NAME_ONLY
GET_CATALOG_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_OBJECT_NAME_ONLY, &env_value, &result_code);

Buffer
typedef struct
{
  char *buffer;
  long max_length;
  long actual_length;
  short value_truncated;
  short index;
  short source_or_target;
} env_value_def;

Input
buffer
A pointer to a buffer to accept the returned object name. The name is null-terminated.

max_length
The maximum length of your allocated buffer to accept the object name. This is returned as a NULL terminated string.

source_or_target
One of the following indicating whether to return the source or target object name.
EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
Output

**buffer**
The fully qualified, null-terminated object name, for example `schema.object` or `catalog.schema.object`, depending on the database platform.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the object name is interpreted in the session character set.

**actual length**
The string length of the returned object name. The actual length does not include the null terminator. The actual length is 0 if the object is a table.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the object name plus the null terminator exceeds the maximum buffer length.

Return Values

- `EXIT_FN_RET_INVALID_COLUMN`
- `EXIT_FN_RET_INVALID_CONTEXT`
- `EXIT_FN_RET_INVALID_PARAM`
- `EXIT_FN_RET_OK`
GET_OPERATION_TYPE

Valid For
Extract and Replicat

Description
Use the GET_OPERATION_TYPE function to determine the operation type associated with a record. Knowing the operation type can be useful in a user exit. For example, the user exit can perform complex validations any time a delete is encountered. It also is important to know when a compressed record is being processed if the user exit is manipulating the full data record.

As an alternative, you can use the GET_RECORD_BUFFER function to determine the operation type (see "GET_RECORD_BUFFER" on page 6-59).

Syntax
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_OPERATION_TYPE, &record, &result_code);

Buffer
typedef struct
{
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;

Input
source_or_target
One of the following indicating whether to return the operation type for the source or the target data record.
EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output
io_type
Returned as one of the following:
- **DDL type:**
  SQL_DDL_VAL

- **DML types:**
  DELETE_VAL
  INSERT_VAL
  UPDATE_VAL

- **Compressed Enscribe update:**
  UPDATE_COMP_ENSCRIBE_VAL

- **Compressed SQL update:**
  UPDATE_COMP_SQL_VAL
  UPDATE_COMP_PK_SQL_VAL

- **Other:**
  TRUNCATE_TABLE_VAL

**Return Values**

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_POSITION

Valid For

Extract (data pump only) and Replicat

Description

Use the GET_POSITION function to obtain a read position of an Extract data pump or Replicat in the Oracle GoldenGate trail.

Syntax

```
#include 'usrdecs.h'
short result_code;
ERCALLBACK (GET_POSITION &position_def, &result_code);
```

Buffer

```
typedef struct
{
    char *position;
    long position_len;
    short position_type;
    short ascii_or_internal;
} position_def;
```

Input

**position_len**
Allocation length for the position length.

**position_type**
Can be one of the following:

- **STARTUP_CHECKPOINT**
  The start position in the trail.

- **CURRENT_CHECKPOINT**
  The position of the last read in the trail.

**column_value_mode**
An indicator for the format in which the column value was passed. Currently, only the default Oracle GoldenGate canonical format is supported, as represented by:

- **EXIT_FN_RAW_FORMAT**

Output

**position**
A pointer to a buffer representing the position values. This buffer is declared in the position_def as two binary values (unsigned int32t and int32t) as seqnorba for eight bytes in a char field. The user exit must move the data to the correct data type. Using this function on a Little Endian platform will cause the process to "reverse bytes" on the two fields individually.
Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_NOT_SUPPORTED
EXIT_FN_RET_OK
GET_RECORD_BUFFER

Valid For

Extract and Replicat

Description

Use the GET_RECORD_BUFFER function to obtain information for custom column conversions. User exits can be used for data mapping between dissimilar source and target records when the COLMAP option of the MAP or TABLE parameter is not sufficient. For example, you can use a user exit to convert a proprietary date field (for example, YYDDD) in an Enscribe database to a standard SQL date in the target record, while other columns are mapped by the Extract process by means of the COLMAP option.

You can use the SET_RECORD_BUFFER function (see "SET_RECORD_BUFFER" on page 6-94) to modify the data retrieved with GET_RECORD_BUFFER. However, it requires an understanding of the data record as written in the internal Oracle GoldenGate canonical format. As an alternative, you can set column values in the data record with the SET_COLUMN_VALUE_BY_INDEX function (see "SET_COLUMN_VALUE_BY_INDEX" on page 6-86) or the SET_COLUMN_VALUE_BY_NAME function (see "STRNCMP" on page 5-53).

Deletes, inserts and updates appear in the buffer as full record images.

Compressed SQL updates have the following format:

```
index length value [index length value ][...]
```

where:

- **index** is a two-byte index into the list of columns of the table (first column is zero).
- **length** is the two-byte length of the table.
- **value** is the actual column value, including one of the following two-byte null indicators when applicable. 0 is not null. -1 is null.

For SQL records, you can use the DECOMPRESS_RECORD function ("DECOMPRESS_RECORD" on page 6-10) to decompress the record for possible manipulation and then use the COMPRESS_RECORD function ("COMPRESS_RECORD" on page 6-8) to compress it again, as expected by the process.

Compressed Enscribe updates have the following format:

```
offset length value [offset length value ][...]
```

where:

- **offset** is the offset into the Enscribe record of the data fragment that changed.
- **length** is the length of the fragment.
- **value** is the data. Fragments can span field boundaries, so full fields are not always retrieved (unless compression is off or FETCHCOMPS is used).

Syntax

```
#include 'usrdecs.h'
short result_code;
record_def record;
```
ERCALLBACK (GET_RECORD_BUFFER, &record, &result_code);

**Buffer**

typedef struct {
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;

**Input**

**source_or_target**

One of the following indicating whether to return the record buffer for the source or target data record.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

**requesting_before_after_ind**

Optional. Set when requesting a record buffer on a record io_type of UPDATE_COMP_PK_SQL_VAL (primary key update). Use one of the following to indicate which portion of the primary key update is to be accessed. The default is AFTER_IMAGE_VAL.

BEFORE_IMAGE_VAL
AFTER_IMAGE_VAL

**Output**

**buffer**

A pointer to the record buffer. Typically, buffer is a pointer to a buffer of type exit_rec_buf_def. The exit_rec_buf_def buffer contains the actual record about to be processed by Extract or Replicat. The buffer is supplied when the call type is EXIT_CALL_DISCARD_RECORD. Exit routines can change the contents of this buffer, for example, to perform custom mapping functions.

The content of the record buffer is not converted to or from the character set of the user exit. It is passed as-is.

**length**

The returned length of the record buffer.

**io_type**

Returned as one of the following:

- **DDL type:**
  SQL_DDL_VAL

6-60 Reference for Oracle GoldenGate for Windows and UNIX
- **DML types:**
  - DELETE_VAL
  - INSERT_VAL
  - UPDATE_VAL

- **Compressed Enscribe update:**
  - UPDATE_COMP_ENSCRIBE_VAL

- **Compressed SQL update:**
  - UPDATE_COMP_SQL_VAL
  - UPDATE_COMP_PK_SQL_VAL

- **Other:**
  - TRUNCATE_TABLE_VAL

**mapped**
A flag (0 or 1) indicating whether or not this is a mapped record buffer.

**before_after_ind**
One of the following to indicate whether the record is a before or after image.
  - BEFORE_IMAGE_VAL
  - AFTER_IMAGE_VAL

**Return Values**
- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_INVALID_PARAM
- EXIT_FN_RET_OK
GET_RECORD_LENGTH

Valid For

Extract and Replicat

Description

Use the GET_RECORD_LENGTH function to retrieve the length of the data record. As an alternative, you can use the GET_RECORD_BUFFER function to retrieve the length of the data record.

Syntax

```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_RECORD_LENGTH, &record, &result_code);
```

Buffer

```c
typedef struct
{
  char *table_name;
  char *buffer;
  long length;
  char before_after_ind;
  short io_type;
  short record_type;
  short transaction_ind;
  int64_t timestamp;
  exit_ts_str io_datetime;
  short mapped;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  char requesting_before_after_ind;
} record_def;
```

Input

**source_or_target**

One of the following indicating whether to return the record length for the source or target data record.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

**length**

The returned length of the data record.

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
**GET_RECORD_TYPE**

**Valid For**

Extract and Replicat

**Description**

Use the `GET_RECORD_TYPE` function to retrieve the type of record being processed. The record can be either a SQL or Enscribe record. The record type is important when manipulating the record buffer, because each record type has a different format.

**Syntax**

```c
#include 'usrdecs.h'
short result_code;
record_def record;
ERCALLBACK (GET_RECORD_TYPE, &record, &result_code);
```

**Buffer**

```c
typedef struct {
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;
```

**Input**

- **source_or_target**
  One of the following indicating whether or not to return the record type for the source or target data record.

  - EXIT_FN_SOURCE_VAL
  - EXIT_FN_TARGET_VAL

**Output**

- **record_type**
  The returned record type. Can be one of the following:
  - For SQL records:
    - EXIT_REC_TYPE_SQL
  - For Enscribe records:
GET_RECORD_TYPE

EXIT_REC_TYPE_ENSCRIBE

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_SCHEMA_NAME_ONLY

Valid For

Extract and Replicat

Description

Use the GET_SCHEMA_NAME_ONLY function to retrieve the name of the owner (such as schema), but not the name of the catalog or container (if applicable) or the object, of the source or target object associated with the record being processed. This function is valid for DML and DDL operations.

To return the fully qualified name of a table, see the following:
GET_TABLE_NAME

To return the fully qualified name of a non-table object, such as a user, view or index, see the following:
GET_OBJECT_NAME

To return only the unqualified table or object name, see the following:
GET_TABLE_NAME_ONLY
GET_OBJECT_NAME_ONLY

To return other parts of the table or object name, see the following:
GET_CATALOG_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

Syntax

```c
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_SCHEMA_NAME_ONLY, &env_value, &result_code);
```

Buffer

```c
typedef struct
{
    char *buffer;
    long max_length;
    long actual_length;
    short value_truncated;
    short index;
    short source_or_target;
} env_value_def;
```

Input

- **buffer**
  A pointer to a buffer to accept the returned schema name. The name is null-terminated.
**max_length**
The maximum length of your allocated buffer to accept the schema name. This is returned as a NULL terminated string.

**source_or_target**
One of the following indicating whether to return the source or target schema name.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

---

**Output**

**buffer**
The fully qualified, null-terminated schema name.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the schema name is interpreted in the session character set.

**actual_length**
The string length of the returned name. The actual length does not include the null terminator.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the schema name plus the null terminator exceeds the maximum buffer length.

---

**Return Values**

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_SESSION_CHARSET

Valid For

Extract and Replicat

Description

Use GET_SESSION_CHARSET to get the current user exit session character set. This character set can be set through callback function SET_SESSION_CHARSET. The character set of the user exit session indicates the encoding of any character-based callback structure members that are used between the user exit and the caller process (Extract, data pump, Replicat), including metadata such as (but not limited to):

- database names and locales
- table and column names
- DDL text
- error messages
- character-type columns such as CHAR and NCHAR
- date-time and numeric columns that are represented in string form

The valid values of the session character set are defined in the header file ucharset.h. This function can be called at any time that the user exit has control.

For more information about globalization support, see Administering Oracle GoldenGate for Windows and UNIX.

Syntax

```c
#include usrdecs.h
short result_code;
session_def session_charset_def;
ERCALLBACK (GET_SESSION_CHARSET, &session_charset_def, &result_code);
```

Buffer

```c
typedef struct
{
  ULibCharSet  session_charset;
} session_def;
```

Input

None

Output

```c
session_charset_def.session_charset
```

Return Values

```c
EXIT_FN_RET_OK
```
GET_STATISTICS

Valid For
Extract and Replicat

Description
Use the GET_STATISTICS function to retrieve the current processing statistics for the Extract or Replicat process. For example, the user exit can output statistics to a custom report should a fatal error occur during Extract or Replicat processing.

Statistics are automatically handled based on which process type has requested the data:

- The Extract process will always treat the request as a source table, counting that table once regardless of the number of times output.
- The Replicat process will always treat the request as a set of target tables. The set includes all counts to the target regardless of the number of source tables.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter.

Syntax

```c
#include "usrdecs.h"
short result_code;
statistics_def statistics;
ERCALLBACK (GET_STATISTICS, &statistics, &result_code);
```

Buffer

typedef struct
{
    char *table_name;
    short group;
    exit_timestamp_string start_datetime;
    long num_inserts;
    long num_updates;
    long num_befores;
    long num_deletes;
    long num_discards;
    long num_ignores;
    long total_db_operations;
    long total_operations;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    long num_truncates;
} statistics_def;

Input

**table_name**
A null-terminated string specifying the fully qualified name of the source table.
Statistics are always recorded against the source records. If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the table name and the date are interpreted in the session character set.
group
Can be one of the following:

**EXIT_STAT_GROUP_STARTUP**
Retrieves statistics since the Oracle GoldenGate process was last started.

**EXIT_STAT_GROUP_DAILY**
Retrieves statistics since midnight of the current day.

**EXIT_STAT_GROUP_HOURLY**
Retrieves statistics since the start of the current hour.

**EXIT_STAT_GROUP_RECENT**
Retrieves statistics since the statistics were reset using GGSCI.

**EXIT_STAT_GROUP_REPORT**
Retrieves statistics since the last report was generated.

**EXIT_STAT_GROUP_USEREXIT**
Retrieves statistics since the last time the user exit reset the statistics with `RESET_USEREXIT_STATS`.

**Output**

**start_datetime**
A null-terminated string in the format of `YYYY-MM-DD HH:MI:SS` indicating the local date and time that statistics started to be recorded for the specified group.

**num_inserts**
The returned number of inserts processed by Extract or Replicat.

**num_updates**
The returned number of updates processed by Extract or Replicat.

**num_befores**
The returned number of update before images processed by Extract or Replicat.

**num_deletes**
The returned number of deletes processed by Extract or Replicat.

**num_discards**
The returned number of records discarded by Extract or Replicat.

**num_ignores**
The returned number of records ignored by Extract or Replicat.

**total_db_operations**
The returned number of total database operations processed by Extract or Replicat.

**total_operations**
The returned number of total operations processed by Extract or Replicat, including discards and ignores.

**num_truncates**
The returned number of truncates processed by Extract or Replicat.
Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_TABLE_NOT_FOUND
EXIT_FN_RET_OK
GET_TABLE_COLUMN_COUNT

Valid For

Extract and Replicat

Description

Use the GET_TABLE_COLUMN_COUNT function to retrieve the total number of columns in a table, including the number of key columns.

Syntax

#include "usrdecs.h"
short result_code;
table_def table;
ERCALLBACK (GET_TABLE_COLUMN_COUNT, &table, &result_code);

Buffer

typedef struct
{
  short num_columns;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  short num_key_columns;
} table_def;

Input

source_or_target
One of the following indicating whether to return the total number of columns for the source or target table.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

num_columns
The returned total number of columns in the specified table.

num_key_columns
The returned total number of columns that are being used by Oracle GoldenGate as the key for the specified table.

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_TABLE_METADATA

Valid For

Extract and Replicat

Description

Use the GET_TABLE_METADATA function to retrieve metadata about the table that associated with the record that is being processed.

Syntax

#include "usrdecs.h"
short result_code;
table_metadata_def tbl_meta_rec;
ERCALLBACK (GET_TABLE_METADATA, &tbl_meta_rec, &result_code);

Buffer

typedef struct
{
  char *table_name;
  short value_truncated;
  long max_name_length;
  long actual_name_length;
  short num_columns;
  short num_key_columns;
  short *key_columns;
  short num_keys_returned;
  BOOL using_pseudo_key;
  short source_or_target;
} table_metadata_def;

Input

table_name
A pointer to a buffer to accept the table_name return value

key_columns
A pointer to an array of key_columns indexes.

max_name_length
The maximum length of the returned table name. Typically, the maximum length is the length of the table name buffer. Since the returned table name is null-terminated, the maximum length should equal the maximum length of the table name.

source_or_target
One of the following indicating whether to return the source or target table name.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL
Output

**table_name**
The name of the table associated with the record that is being processed. If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the table name is interpreted in the session character set.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the table name plus the null terminator exceeds the maximum buffer length.

**actual_name_length**
The string length of the returned table name. The actual length does not include the null terminator.

**num_columns**
The number of columns in the table.

**num_key_columns**
The number of columns in the key that is being used by Oracle GoldenGate.

**key_columns**
The values for the key columns. You must know the expected number of keys multiplied by the length of the columns, and then allocate the appropriate amount of buffer.

**num_keys_returned**
The number of key columns that are requested.

**using_pseudo_key**
A flag that indicates whether or not `KEYCOLS`-specified columns are being used as a key. Returns `TRUE` or `FALSE`.

Return Values

- `EXIT_FN_RET_INVALID_PARAM`
- `EXIT_FN_RET_INVALID_CONTEXT`
- `EXIT_FN_RET_EXCEEDED_MAX_LENGTH`
- `EXIT_FN_RET_OK`
GET_TABLE_NAME

Valid For

Extract and Replicat

Description

Use the GET_TABLE_NAME function to retrieve the fully qualified name of the source or target table associated with the record being processed. This function is valid only for tables in DML and DDL operations. To retrieve the fully qualified name of a non-table object, see the following:

GET_OBJECT_NAME

To return only part of the fully qualified name, see also the following:

GET_TABLE_NAME_ONLY
GET_SCHEMA_NAME_ONLY
GET_CATALOG_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

This function returns a value only if the object is a table. Otherwise, the actual_length of the env_value_def variable returns 0.

Syntax

```c
#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_TABLE_NAME, &env_value, &result_code);
```

Buffer

```c
typedef struct
{
    char *buffer;
    long max_length;
    long actual_length;
    short value_truncated;
    short index;
    short source_or_target;
} env_value_def;
```

Input

**buffer**
A pointer to a buffer to accept the returned table name. The table name is null-terminated.

**max_length**
The maximum length of your allocated buffer to accept the table name. This is returned as a NULL terminated string.
source_or_target
One of the following indicating whether to return the source or target table name.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

Output

buffer
The fully qualified, null-terminated table name, for example schema.table or catalog.schema.table, depending on the database platform.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the table name is interpreted in the session character set.

actual_length
The string length of the returned table name. The actual length does not include the null terminator. The actual length returned is 0 if the object is anything other than a table.

value_truncated
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the table name plus the null terminator exceeds the maximum buffer length.

Return Values

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
GET_TABLE_NAME_ONLY

Valid For

Extract and Replicat

Description

Use the GET_TABLE_NAME_ONLY function to retrieve the unqualified name (without the catalog, container, or schema) of the source or target table associated with the record being processed. This function is valid only for tables in DML and DDL operations. To retrieve the unqualified name of a non-table object, see the following:

GET_OBJECT_NAME_ONLY

To return the fully qualified name of a table, see the following:

GET_TABLE_NAME

To return other parts of the table name, see the following:

GET_SCHEMA_NAME_ONLY
GET_CATALOG_NAME_ONLY

Database object names are returned exactly as they are defined in the hosting database, including the letter case.

This function returns a value only if the object is a table. Otherwise, the actual_length of the env_value_def variable returns 0.

Syntax

#include "usrdecs.h"
short result_code;
env_value_def env_value;
ERCALLBACK (GET_TABLE_NAME_ONLY, &env_value, &result_code);

Buffer

typedef struct
{
    char *buffer;
    long max_length;
    long actual_length;
    short value_truncated;
    short index;
    short source_or_target;
} env_value_def;

Input

buffer
A pointer to a buffer to accept the returned table name. The table name is null-terminated.

max_length
The maximum length of your allocated buffer to accept the table name. This is returned as a NULL terminated string.
**source_or_target**
One of the following indicating whether to return the source or target table name.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

**Output**

**buffer**
The fully qualified, null-terminated table name, for example schema.table or catalog.schema.table, depending on the database platform.

If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the table name is interpreted in the session character set.

**actual length**
The string length of the returned table name. The actual length does not include the null terminator. The actual length returned is 0 if the object is anything other than a table.

**value_truncated**
A flag (0 or 1) indicating whether or not the value was truncated. Truncation occurs if the length of the table name plus the null terminator exceeds the maximum buffer length.

**Return Values**

EXIT_FN_RET_INVALID_COLUMN
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
**GET_TIMESTAMP**

**Valid For**

Extract and Replicat

**Description**

Use the GET_TIMESTAMP function to retrieve the I/O timestamp associated with a source data record in ASCII datetime format. The timestamp is then converted to local time and approximates the time of the original database operation.

---

**Note:** The ASCII commit timestamp can vary with the varying regional use of Daylight Savings Time. The user exit callback should return the ASCII datetime as a GMT time to avoid this variance. The Oracle GoldenGate trail uses GMT format. See “GET_GMT_TIMESTAMP” on page 6-48.

---

**Syntax**

```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_TIMESTAMP, &record, &result_code);
```

**Buffer**

```c
typedef struct
{
  char *table_name;
  char *buffer;
  long length;
  char before_after_ind;
  short io_type;
  short record_type;
  short transaction_ind;
  int64_t timestamp;
  exit_ts_str io_datetime;
  short mapped;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  char requesting_before_after_ind;
} record_def;
```

**Input**

None

**Output**

- **timestamp**
  The returned 64-bit I/O timestamp in ASCII format.

- **io_datetime**
  A null-terminated string containing the local I/O date and time, in the format of:
YYYY-MM-DD HH:MI:SS.FFFFFFF

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
GET_TRANSACTION_IND

Valid For
Extract and Replicat

Description
Use the GET_TRANSACTION_IND function to determine whether a data record is the first, last or middle operation in a transaction. This can be useful when, for example, a user exit can compile the details of each transaction and output a special summary record.

Syntax
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (GET_TRANSACTION_IND, &record, &result_code);

Buffer
typedef struct
{
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;

Input
None

Output
transaction_ind
The returned transaction indicator, represented as one of the following:

BEGIN_TRANS_VAL
The record is the beginning of a transaction.

MIDDLE_TRANS_VAL
The record is in the middle of a transaction.

END_TRANS_VAL
The record is the end of a transaction.
WHOLE_TRANS_VAL
The record is the only one in the transaction.

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_OK
GET_USER_TOKEN_VALUE

Valid For

Extract and Replicat

Description

Use the GET_USER_TOKEN_VALUE function to obtain the value of a user token from a trail record. No character-set conversion is performed on the token value.

Syntax

```c
#include "usrdecs.h"
```

Buffer

typedef struct
{
    char *token_name;
    char *token_value;
    long max_length;
    long actual_length;
    short value_truncated;
} token_value_def;

Input

token_name
A pointer to a buffer representing the name of a token. It is assumed that the token name is encoded in the default character set of the operating system that hosts the Extract TABLE statement where the token is configured. The user exit prepares the token name in the character set that is specified with SET_SESSION_CHARSET, but converts it back to the operating system character set before retrieving the matching token value.

max_length
The maximum length of your allocated token_name buffer to accept any resulting token value. This is returned as a NULL terminated string.

Output

token_value
A pointer to a buffer representing the return value (if any) of a token. The token value is passed back to the user exit as-is, without any character-set conversion.

actual_length
The actual length of the token value that is returned. A value of 0 is returned if the token is found and there is no value present.

value_truncated
A flag of either 0 or 1 that indicates whether or not the token value was truncated. Truncation occurs if the length of the table name plus the null terminator exceeds the maximum buffer length.
Return Values

EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_TOKEN_NOT_FOUND
EXIT_FN_RET_OK
**OUTPUT_MESSAGE_TO_REPORT**

**Valid For**

Extract and Replicat

**Description**

Use the `OUTPUT_MESSAGE_TO_REPORT` function to output a message to the report file. If a character session for the user exit is set with `SET_SESSION_CHARSET`, the message is interpreted in the session character set but is converted to the default character set of the operating system before being written to the report file.

**Syntax**

```c
#include "usrdecs.h"
short result_code;
char message[500];
ERCALLBACK (OUTPUT_MESSAGE_TO_REPORT, message, &result_code);
```

**Buffer**

None

**Input**

`message`  
A null-terminated string.

**Output**

None

**Return Values**

`EXIT_FN_RET_OK`
RESET_USEREXIT_STATS

Valid For

Extract and Replicat

Description

Use the RESET_USEREXIT_STATS function to reset the EXIT_STAT_GROUP_USEREXIT statistics for the Oracle GoldenGate process since the last call to GET_STATISTICS was processed. This function enables the user exit to control when to reset the group statistics that are returned by the GET_STATISTICS function, but does not permit any of the other statistics to be reset.

Syntax

#include "usrdecs.h"
short result_code;
call_callback(RESET_USEREXIT_STATS, NULL, &result_code);

Input

None

Output

None

Return Values

None
SET_COLUMN_VALUE_BY_INDEX

Valid For

Extract and Replicat

Description

Use the SET_COLUMN_VALUE_BY_INDEX or SET_COLUMN_VALUE_BY_NAME function to modify a single column value without manipulating the entire data record. If the character session of the user exit is set with SET_SESSION_CHARSET to a value other than the default character set of the operating system, as defined in ULIB_CS_DEFAULT in the ucharset.h file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

A column value is set to the session character set only if the following is true:

- The column value is a SQL character type (CHAR/VARCHAR2/CLOB, NCHAR/NVARCHAR2/NCLOB), a SQL date/timestamp/interval/number type
- The column_value_mode indicator is set to EXIT_FN_CNVTED_SESS_CHAR_FORMAT.

Syntax

```c
#include "usrdecs.h"
short result_code;
column_def column;
ERCALLBACK (SET_COLUMN_VALUE_BY_INDEX, &column, &result_code);
```

Buffer

```c
typedef struct 
{
    char *column_value;
    unsigned short max_value_length;
    unsigned short actual_value_length;
    short null_value;
    short remove_column;
    short value_truncated;
    short column_index;
    char *column_name;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    short column_value_mode;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
    char more_lob_data;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    ULibCharSet column_charset;
} column_def;
```

Input

`column_value`

A pointer to a buffer representing the new column value.
The length of the new column value, in bytes. The actual length should not include the null terminator if the new column value is in ASCII format.

A flag (0 or 1) indicating whether the new column value is null. If the null_value flag is set to 1, the column value in the data record is set to null.

A flag (0 or 1) indicating whether to remove the column from a compressed update if it exists. A compressed update is one in which only the changed column values are logged, not all of the column values. This flag should only be set if the operation type for the record is UPDATE_COMP_SQL_VAL, PK_UPDATE_SQL_VAL, or UPDATE_COMP_ENSCRIBE_VAL.

The column index of the new column value to be copied into the data record buffer. Column indexes start at zero.

Indicates the format of the column value.

**EXIT_FN_CHAR_FORMAT**
ASCII format: The value is a null-terminated ASCII (or EBCDIC) string (with a known exception for the sub-data type UTF16_BE, which is converted to UTF8.)

**Note:** A column value might be truncated when presented to a user exit, because the value is interpreted as an ASCII string and is supposed to be null-terminated. The first value of 0 becomes the string terminator.

- Dates are in the format CCYY-MM-DD HH:MI:SS.FFFFFF, in which the fractional time is database-dependent.
- Numeric values are in their string format. For example, 123.45 is represented as '123.45'.
- Non-printable characters or binary values are converted to hexadecimal notation.
- Floating point types are output as null-terminated strings, to the first 14 significant digits.

**EXIT_FN_RAW_FORMAT**
Internal Oracle GoldenGate canonical format: This format includes a two-byte null indicator and a two-byte variable data length when applicable. No character-set conversion is performed by Oracle GoldenGate for this format for any character data type.

**EXIT_FN_CNVTED_SESS_CHAR_FORMAT**
User exit character set: This only applies if the column data type is:
- a character-based type, single or multi-byte
- a numeric type with a string representation
This format is not null-terminated.
**source_or_target**
One of the following indicating whether the source or target record is being modified.

- EXIT_FN_SOURCE_VAL
- EXIT_FN_TARGET_VAL

**requesting_before_after_ind**
Set when setting a column value on a record io_type of UPDATE_COMP_PK_SQL_VAL (primary key update). Use one of the following to indicate which portion of the primary key update is to be accessed. The default is AFTER_IMAGE_VAL.

- BEFORE_IMAGE_VAL
- AFTER_IMAGE_VAL

**Output**

None

**Return Values**

- EXIT_FN_RET_BAD_COLUMN_DATA
- EXIT_FN_RET_INVALID_COLUMN
- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_INVALID_PARAM
- EXIT_FN_RET_OK
- EXIT_FN_RET_NOT_SUPPORTED
- EXIT_FN_RET_INVALID_COLUMN_TYPE
**SET_COLUMN_VALUE_BY_NAME**

**Valid For**

Extract and Replicat

**Description**

Use the `SET_COLUMN_VALUE_BY_NAME` or `SET_COLUMN_VALUE_BY_INDEX` function to modify a single column value without manipulating the entire data record.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the character data that is exchanged between the user exit and the process is interpreted in the session character set.

A column value is set to the session character set only if the following is true:

- The column value is a SQL character type (`CHAR/VARCHAR2/CLOB`, `NCHAR/NVARCHAR2/NCLOB`), a SQL date/timestamp/interval/number type
- The `column_value_mode` indicator is set to `EXIT_FN_CNVTED_SESS_CHAR_FORMAT`.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter.

**Syntax**

```c
#include "usrdecs.h"
short result_code;
column_def column;
ERCALLBACK (SET_COLUMN_VALUE_BY_NAME, &column, &result_code);
```

**Buffer**

```c
typedef struct
{
    char *column_value;
    unsigned short max_value_length;
    unsigned short actual_value_length;
    short null_value;
    short remove_column;
    short value_truncated;
    short column_index;
    char *column_name;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    short column_value_mode;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
    char more_lob_data;
    /* Version 3 CALLBACK_STRUCT_VERSION */
    ULibCharSet column_charset;
} column_def;
```

**Input**

`column_value`

A pointer to a buffer representing the new column value.
**actual_value_length**
The length of the new column value, in bytes. The actual length should not include the null terminator if the new column value is in ASCII format.

**null_value**
A flag (0 or 1) indicating whether the new column value is null. If the null_value flag is set to 1, the column value in the data record is set to null.

**remove_column**
A flag (0 or 1) indicating whether to remove the column from a compressed update if it exists. A compressed update is one where only the changed column values are logged, not all of the column values. This flag should only be set if the operation type for the record is UPDATE_COMP_SQL_VAL, PK_UPDATE_SQL_VAL, or UPDATE_COMP_ENSCRIBE_VAL.

**column_name**
The name of the column that corresponds to the new column value to be copied into the data record buffer.

**column_value_mode**
Indicates the format of the column value.

**EXIT_FN_CHAR_FORMAT**
ASCII format: The value is a null-terminated ASCII (or EBCDIC) string (with a known exception for the sub-data type UTF16_BE, which is converted to UTF8.)

---

**Note:** A column value might be truncated when presented to a user exit, because the value is interpreted as an ASCII string and is supposed to be null-terminated. The first value of 0 becomes the string terminator.

- Dates are in the format CCYY-MM-DD HH:MI:SS.FFFFFF, in which the fractional time is database-dependent.
- Numeric values are in their string format. For example, 123.45 is represented as '123.45'.
- Non-printable characters or binary values are converted to hexadecimal notation.
- Floating point types are output as null-terminated strings, to the first 14 significant digits.

**EXIT_FN_RAW_FORMAT**
Internal Oracle GoldenGate canonical format: This format includes a two-byte null indicator and a two-byte variable data length when applicable. No character-set conversion is performed by Oracle GoldenGate for this format for any character data type.

**EXIT_FN_CNVTED_SESS_CHAR_FORMAT**
User exit character set: This only applies if the column data type is:
- a character-based type, single or multi-byte
- a numeric type with a string representation

This format is not null-terminated.
**source_or_target**
One of the following indicating whether the source or the target data record is being modified.

- EXIT_FN_SOURCE_VAL
- EXIT_FN_TARGET_VAL

**requesting_before_after_ind**
Set when setting a column value on a record io_type of UPDATE_COMP_PK_SQL_VAL (primary key update). Use one of the following to indicate which portion of the primary key update is to be accessed. The default is AFTER_IMAGE_VAL.

- BEFORE_IMAGE_VAL
- AFTER_IMAGE_VAL

**Output**
None

**Return Values**

- EXIT_FN_RET_BAD_COLUMN_DATA
- EXIT_FN_RET_INVALID_COLUMN
- EXIT_FN_RET_INVALID_CONTEXT
- EXIT_FN_RET_INVALID_PARAM
- EXIT_FN_RET_OK
- EXIT_FN_RET_NOT_SUPPORTED
- EXIT_FN_RET_INVALID_COLUMN_TYPE
**SET_OPERATION_TYPE**

**Valid For**

Extract and Replicat

**Description**

Use the SET_OPERATION_TYPE function to change the operation type associated with a data record. For example, a delete on a specified table can be turned into an insert into another table. The record header's before/after indicator is modified as appropriate for insert and delete operations.

**Syntax**

```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (SET_OPERATION_TYPE, &record, &result_code);
```

**Buffer**

```c
typedef struct
{
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION */
    char requesting_before_after_ind;
} record_def;
```

**Input**

**io_type**

Returned as one of the following for deletes, inserts, and updates, respectively:

- DELETE_VAL
- INSERT_VAL
- UPDATE_VAL

For a compressed Enscribe update, the following is returned:

- UPDATE_COMP_ENSCRIBE_VAL

For a compressed SQL update, the following is returned:

- UPDATE_COMP_SQL_VAL

If the new operation type is an insert or delete, the before/after indicator for the record is set to one of the following:
**Insert:** AFTER_IMAGE_VAL (after image)

**Delete:** BEFORE_IMAGE_VAL (before image)

**source_or_target**
One of the following indicating whether to set the operation type for the source or target data record.

EXIT_FN_SOURCE_VAL
EXIT_FN_TARGET_VAL

**Output**
None

**Return Values**

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
SET_RECORD_BUFFER

Valid For

Extract and Replicat

Description

Use the SET_RECORD_BUFFER function for compatibility with user exits, and for complex data record manipulation. This function manipulates the entire record. It is best to modify individual column values, rather than the entire record, because the Oracle GoldenGate internal record formats must be known in order to accurately modify the data record buffer directly. To modify column values, use the SET_COLUMN_VALUE_BY_INDEX and SET_COLUMN_VALUE_BY_NAME functions. These functions are sufficient to handle most custom mapping within a user exit.

Syntax

```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (SET_RECORD_BUFFER, &record_def, &result_code);
```

Buffer

typedef struct
{
  char *table_name;
  char *buffer;
  long length;
  char before_after_ind;
  short io_type;
  short record_type;
  short transaction_ind;
  int64_t timestamp;
  exit_ts_str io_datetime;
  short mapped;
  short source_or_target;
  /* Version 2 CALLBACK_STRUCT_VERSION */
  char requesting_before_after_ind;
} record_def;

Input

**buffer**

A pointer to the new record buffer. Typically, `buffer` is a pointer to a buffer of type `exit_rec_buf_def`. The `exit_rec_buf_def` buffer contains the actual record about to be processed by Extract or Replicat. The buffer is supplied when the call type is `EXIT_CALL_DISCARD_RECORD`. Exit routines can change the contents of this buffer, for example to perform custom mapping functions.

The content of the record buffer is not converted to or from the character set of the user exit. It is passed as-is.

**length**

The new length of the record buffer.
Output

None

Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
EXIT_FN_RET_NOT_SUPPORTED
### SET_SESSION_CHARSET

#### Valid For

Extract and Replicat

#### Description

Use the `SET_SESSION_CHARSET` function to set the character set of the user exit. The character set of the user exit session indicates the encoding of any character-based callback structure members that are used between the user exit and the caller process (Extract, data pump, Replicat), including metadata such as (but not limited to):

- database names and locales
- table and column names
- DDL text
- error messages
- character-type columns such as `CHAR` and `NCHAR`
- date-time and numeric columns that are represented in string form

This function can be called at any time that the user exit has control. When the user exit sets the session character set, it takes effect immediately, and all character values start being converted to the specified set. The recommended place to call this function is with call type `EXIT_CALL_START`.

If `SET_SESSION_CHARSET` is not called, the session gets set to the default character set of the operating system, which is a predefined enumerated type value in `ULIB_CS_DEFAULT` in the `ucharset.h` file. When the session character set is a default from `ULIB_CS_DEFAULT`, no conversion is performed by Oracle GoldenGate for character-type values that are exchanged between the user exit and the caller process. In addition, the object-name metadata of the database are considered to be the default character set of the operating system. Keep in mind that the default may not be correct.

The character set of the user exit is printed to the report file when the user exit is loaded and when `SET_SESSION_CHARSET` is called. If the session character set is `ULIB_CS_DEFAULT`, there is a message stating that no column data character-set conversion is being performed.

For more information about globalization support, see *Administering Oracle GoldenGate for Windows and UNIX*.

#### Syntax

```c
#include usrdecs.h
short result_code;
session_def session_charset_def;
ERCALLBACK (SET_SESSION_CHARSET, &session_charset_def, &result_code);
```

#### Buffer

```c
typedef struct
{
```
ULibCharSet  session_charset;
) session_def;

Input

session_charset
The valid values of the session character set are defined in the header file ucharset.h.

Output

None

Return Values

EXIT_FN_RET_OK
**SET_TABLE_NAME**

**Valid For**

Extract and data pumps

**Description**

Use the `SET_TABLE_NAME` function to change the table name associated with a data record. For example, a delete on a specified table can be changed to an insert into a history table. You can change the table name only during Extract processing.

If the database is case-sensitive, object names must be specified in the same letter case as they are defined in the hosting database; otherwise, the case does not matter. Specify the full two-part or three-part table name.

**Syntax**

```c
#include "usrdecs.h"
short result_code;
record_def record;
ERCALLBACK (SET_TABLE_NAME, &record_def, &result_code);
```

**Buffer**

```c
typedef struct {
    char *table_name;
    char *buffer;
    long length;
    char before_after_ind;
    short io_type;
    short record_type;
    short transaction_ind;
    int64_t timestamp;
    exit_ts_str io_datetime;
    short mapped;
    short source_or_target;
    /* Version 2 CALLBACK_STRUCT_VERSION   */
    char requesting_before_after_ind;
} record_def;
```

**Input**

`table_name`

A null-terminated string specifying the new table name to be associated with the data record.

If the character session of the user exit is set with `SET_SESSION_CHARSET` to a value other than the default character set of the operating system, as defined in `ULIB_CS_DEFAULT` in the `ucharset.h` file, the table name is interpreted in the session character set.

**Output**

None
Return Values

EXIT_FN_RET_INVALID_CONTEXT
EXIT_FN_RET_INVALID_PARAM
EXIT_FN_RET_OK
