Oracle® Fusion Middleware
Getting Started With JAX-RPC Web Services for Oracle WebLogic Server
11g Release 1 (10.3.6)
E13760-07

April 2015
Documentation for software developers that describes how to develop WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

4 Programming the JWS File

4.1 Overview of JWS Files and JWS Annotations................................. 4-1
4.2 Java Requirements for a JWS File ............................................... 4-2
4.3 Programming the JWS File: Typical Steps................................... 4-2
4.3.1 Example of a JWS File ............................................................ 4-3
4.3.2 Specifying that the JWS File Implements a Web Service
   (@WebService Annotation) ...................................................... 4-4
4.3.3 Specifying the Mapping of the Web Service to the SOAP Message Protocol
   (@SOAPBinding Annotation) .................................................. 4-5
4.3.4 Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation)
   ................................................................. 4-5
4.3.5 Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and
   @OneWay Annotations) .................................................. 4-6
4.3.6 Customizing the Mapping Between Operation Parameters and WSDL Elements
   (@WebParam Annotation) .................................................. 4-7
4.3.7 Customizing the Mapping Between the Operation Return Value and a WSDL Element
   (@WebResult Annotation) .................................................. 4-7
4.4 Accessing Run-Time Information About a Web Service.................... 4-8
4.4.1 Using JwsContext to Access Run-Time Information .................... 4-8
4.4.1.1 Guidelines for Accessing the Web Service Context... 4-8
4.4.1.2 Methods of the JwsContext ............................................ 4-9
4.4.2 Using the Stub Interface to Access Run-Time Information ............. 4-12
4.5 Should You Implement a Stateless Session EJB? .............................. 4-13
4.5.1 Programming Guidelines When Implementing an EJB in Your JWS File... 4-13
4.5.2 Example of a JWS File That Implements an EJB ........................... 4-14
4.6 Programming the User-Defined Java Data Type .............................. 4-15
4.7 Throwing Exceptions........................................................................ 4-16
4.8 Invoking Another Web Service from the JWS File ............................ 4-18
4.9 Programming Additional Miscellaneous Features Using JWS
   Annotations and APIs ............................................................... 4-18
4.9.1 Sending Binary Data Using MTOM/XOP .................................. 4-19
4.9.2 Streaming SOAP Attachments ............................................. 4-21
4.9.3 Using SOAP 1.2 .................................................................. 4-21
4.9.4 Specifying that Operations Run Inside of a Transaction .............. 4-22
7.9 Using Work Managers to Prioritize Web Services Work and Reduce Stuck Execute Threads ................................................................. 7-10

8 Upgrading WebLogic Web Services From Previous Releases to 10.3.x

8.1 Upgrading a 9.2 or 10.0 WebLogic Web Service to 10.3.x ................................. 8-1
8.2 Upgrading a 9.0 or 9.1 WebLogic Web Service to 10.3.x ................................. 8-1
8.3 Upgrading an 8.1 WebLogic Web Service to 10.3.x ........................................... 8-2
8.3.1 Upgrading an 8.1 Java Class-Implemented WebLogic Web Service to 10.3.x: Main Steps ........................................................................................................ 8-3
8.3.1.1 Example of an 8.1 Java File and the Corresponding 10.3.x JWS File ............... 8-5
8.3.1.2 Example of an 8.1 and Updated 10.3.x Ant Build File for Java Class-Implemented Web Services ........................................................................................................ 8-6
8.3.2 Upgrading an 8.1 EJB-Implemented WebLogic Web Service to 10.3.x: Main Steps 8-7
8.3.2.1 Example of 8.1 EJB Files and the Corresponding 10.3.x JWS File .................. 8-9
  8.3.2.1.1 8.1 SessionBean Class ................................................................................. 8-9
  8.3.2.1.2 8.1 Remote Interface .................................................................................. 8-11
  8.3.2.1.3 8.1 EJB Home Interface ............................................................................ 8-11
  8.3.2.1.4 Equivalent 10.3.x JWS File ........................................................................ 8-11
8.3.2.2 Example of an 8.1 and Updated 10.3.x Ant Build File for an 8.1 EJB-Implemented Web Service ........................................................................................................ 8-12
8.3.3 Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes ...... 8-14
This preface describes the document accessibility features and conventions used in this guide—Getting Started With JAX-RPC Web Services for Oracle WebLogic Server.

Documentation Accessibility
For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support
Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Conventions
The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>boldface</td>
<td>Boldface type indicates graphical user interface elements associated</td>
</tr>
<tr>
<td></td>
<td>with an action, or terms defined in text or the glossary.</td>
</tr>

<td>for which you supply particular values.</td>
</tr>
<tr>
<td>monospace</td>
<td>Monospace type indicates commands within a paragraph, URLs, code in</td>
</tr>
<tr>
<td></td>
<td>examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
This chapter provides a summary table of getting started topics for software developers who program WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

JAX-RPC is a specification that defines the Java APIs for making XML-based remote procedure calls (RPC). In particular, these APIs are used to invoke and get a response from a Web service using SOAP 1.1, and XML-based protocol for exchange of information in a decentralized and distributed environment. For more information, see http://java.net/projects/jax-rpc/.

---

Note: JAX-WS is designed to take the place of JAX-RPC in Web services and Web applications. To compare the features that are supported for JAX-WS and JAX-RPC, see “How Do I Choose Between JAX-WS and JAX-RPC?” in Oracle Fusion Middleware Introducing WebLogic Web Services for Oracle WebLogic Server.

The following table summarizes the contents of this guide.

**Table 1–1  Content Summary**

For an overview of WebLogic Web services, standards, samples, and related documentation, see Oracle Fusion Middleware Introducing WebLogic Web Services for Oracle WebLogic Server.
For information about WebLogic Web service security, see *Oracle Fusion Middleware Securing WebLogic Web Services for Oracle WebLogic Server*. 
This chapter describes common use cases and examples for WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- Section 2.1, "Creating a Simple HelloWorld Web Service"
- Section 2.2, "Creating a Web Service With User-Defined Data Types"
- Section 2.3, "Creating a Web Service from a WSDL File"
- Section 2.4, "Invoking a Web Service from a Java SE Client"
- Section 2.5, "Invoking a Web Service from a WebLogic Web Service"

Each use case provides step-by-step procedures for creating simple WebLogic Web services and invoking an operation from a deployed Web service. The examples include basic Java code and Ant build.xml files that you can use in your own development environment to recreate the example, or by following the instructions to create and run the examples in an environment that is separate from your development environment.

The use cases do not go into detail about the processes and tools used in the examples; later chapters are referenced for more detail.

### 2.1 Creating a Simple HelloWorld Web Service

This section describes how to create a very simple Web service that contains a single operation. The Java Web Service (JWS) file that implements the Web service uses just the one required JWS annotation: `@WebService`. A JWS file is a standard Java file that uses JWS metadata annotations to specify the shape of the Web service. Metadata annotations were introduced with JDK 5.0, and the set of annotations used to annotate Web service files are called JWS annotations. WebLogic Web services use standard JWS annotations. For a complete list of JWS annotations that are supported, see "Web Service Annotation Support" in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server.

The following example shows how to create a Web service called HelloWorldService that includes a single operation, `sayHelloWorld`. For simplicity, the operation returns the inputted String value.

1. **Set your WebLogic Server environment.**

   Open a command window and execute the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is `MW_HOME/user_`
2. Create a project directory, as follows:

    prompt> mkdir /myExamples/hello_world

3. Create a src directory under the project directory, as well as subdirectories that correspond to the package name of the JWS file (shown later in this procedure):

    prompt> cd /myExamples/hello_world
    prompt> mkdir src/examples/webservices/hello_world

4. Create the JWS file that implements the Web service.

    Open your favorite Java IDE or text editor and create a Java file called HelloWorldImpl.java using the Java code specified in Section 2.1.1, "Sample HelloWorldImpl.java JWS File."

    The sample JWS file shows a Java class called HelloWorldImpl that contains a single public method, sayHelloWorld(String). The @WebService annotation specifies that the Java class implements a Web service called HelloWorldService. By default, all public methods are exposed as operations.

5. Save the HelloWorldImpl.java file in the src/examples/webservices/hello_world directory.

6. Create a standard Ant build.xml file in the project directory (myExamples/hello_world/src) and add a taskdef Ant task to specify the full Java classname of the jwsc task:

    <project name="webservices-hello_world" default="all">
    <taskdef name="jwsc" classname="weblogic.wsee.tools.anttasks.JwscTask" />
    </project>

    See Section 2.1.2, "Sample Ant Build File for HelloWorldImpl.java" for a full sample build.xml file that contains additional targets from those described in this procedure, such as clean, undeploy, client, and run. The full build.xml file also uses properties, such as ${ear-dir}, rather than always using the hard-coded name for the EAR directory.

7. Add the following call to the jwsc Ant task to the build.xml file, wrapped inside of the build-service target:

    <target name="build-service">
    <jwsc
        srcdir="src"
        destdir="output/helloWorldEar">
        <jws file="examples/webservices/hello_world/HelloWorldImpl.java"
            type="JAXRPC"/>
    </jwsc>
    </target>

    The jwsc WebLogic Web service Ant task generates the supporting artifacts (such as the deployment descriptors, serialization classes for any user-defined data types, the WSDL file, and so on), compiles the user-created and generated Java code, and archives all the artifacts into an Enterprise Application EAR file that you later deploy to WebLogic Server.

8. Execute the jwsc Ant task by specifying the build-service target at the command line:
Creating a Simple HelloWorld Web Service

Use Cases and Examples

2.1 Sample HelloWorldImpl.java JWS File

```java
package examples.webservices.hello_world;
// Import the @WebService annotation
import javax.jws.WebService;

@WebService(name="HelloWorldPortType", serviceName="HelloWorldService")
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHelloWorld
*/
```
public class HelloWorldImpl {
    // By default, all public methods are exposed as Web Services operation
    public String sayHelloWorld(String message) {
        try {
            System.out.println('sayHelloWorld: ' + message);
        } catch (Exception ex) { ex.printStackTrace(); }
        return "Here is the message: '" + message + "';";
    }
}

2.1.2 Sample Ant Build File for HelloWorldImpl.java

The following build.xml file uses properties to simplify the file.

    <project name="webservices-hello_world" default="all">
    <!-- set global properties for this build -->
    <property name="wls.username" value="weblogic" />
    <property name="wls.password" value="weblogic" />
    <property name="wls.hostname" value="localhost" />
    <property name="wls.port" value="7001" />
    <property name="wls.server.name" value="myserver" />
    <property name="ear.deployed.name" value="helloWorldEar" />
    <property name="example-output" value="output" />
    <property name="clientclass-dir" value="${example-output}/clientclasses" />
    <path id="client.class.path">
        <pathelement path="${clientclass-dir}"
        </path>
    </target>
    <target name="build-service">
        <jwsc
            srcdir="src"
            destdir="${ear-dir}"
            jws file="examples/webservices/hello_world/HelloWorldImpl.java"
            type="JAXRPC"/>
    </jwsc>
    </target>
    <target name="deploy">
        <wldeploy action="deploy" name="${ear.deployed.name}" Source="${ear-dir}" user="${wls.username}" password="${wls.password}" verbose="true"
        adminurl="t3://${wls.hostname}:${wls.port}"
        targets="${wls.server.name}" />
    </target>
    <target name="undeploy">
        <wldeploy action="undeploy" name="${ear.deployed.name}" failonerror="false"
Creating a Web Service With User-Defined Data Types

The preceding use case uses only a simple data type, String, as the parameter and return value of the Web service operation. This next example shows how to create a Web service that uses a user-defined data type, in particular a JavaBean called BasicStruct, as both a parameter and a return value of its operation.

There is actually very little a programmer has to do to use a user-defined data type in a Web service, other than to create the Java source of the data type and use it correctly in the JWS file. The jwsc Ant task, when it encounters a user-defined data type in the JWS file, automatically generates all the data binding artifacts needed to convert data between its XML representation (used in the SOAP messages) and its Java representation (used in WebLogic Server). The data binding artifacts include the XML Schema equivalent of the Java user-defined type, the JAX-RPC type mapping file, and so on.

The following procedure is very similar to the procedure in Section 2.1, "Creating a Simple HelloWorld Web Service." For this reason, although the procedure does show all the needed steps, it provides details only for those steps that differ from the simple HelloWorld example.

1. Set your WebLogic Server environment.

   Open a command window and execute the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is MW_HOME/user_projects/domains/domainName, where MW_HOME is the top-level installation directory of the Oracle products and domainName is the name of your domain.

2. Create a project directory:

   prompt> mkdir /myExamples/complex
3. Create a `src` directory under the project directory, as well as subdirectories that correspond to the package name of the JWS file (shown later in this procedure):

   ```
prompt> cd /myExamples/complex
prompt> mkdir src/examples/webservices/complex
   ```

4. Create the source for the `BasicStruct` JavaBean.

   Open your favorite Java IDE or text editor and create a Java file called `BasicStruct.java`, in the project directory, using the Java code specified in Section 2.2.1, “Sample BasicStruct JavaBean.”

5. Save the `BasicStruct.java` file in the `src/examples/webservices/complex` subdirectory of the project directory.

6. Create the JWS file that implements the Web service using the Java code specified in Section 2.2.2, "Sample ComplexImpl.java JWS File."

   The sample JWS file uses several JWS annotations: `@WebMethod` to specify explicitly that a method should be exposed as a Web service operation and to change its operation name from the default method name `echoStruct` to `echoComplexType`; `@WebParam` and `@WebResult` to configure the parameters and return values; `@SOAPBinding` to specify the type of Web service; and `@WLHttpTransport` to specify the URI used to invoke the Web service. The `ComplexImpl.java` JWS file also imports the `examples.webservice.complex.BasicStruct` class and then uses the `BasicStruct` user-defined data type as both a parameter and return value of the `echoStruct()` method.

   For more in-depth information about creating a JWS file, see Chapter 4, “Programming the JWS File.”

7. Save the `ComplexImpl.java` file in the `src/examples/webservices/complex` subdirectory of the project directory.

8. Create a standard Ant `build.xml` file in the project directory and add a `taskdef` Ant task to specify the fully Java classname of the `jwsc` task:

   ```
<project name="webservices-complex" default="all">
   <taskdef name="jwsc"
      classname="weblogic.wsee.tools.anttasks.JwscTask" />
</project>
   ```

   See Section 2.2.3, "Sample Ant Build File for ComplexImpl.java JWS File” for a full sample `build.xml` file.

9. Add the following call to the `jwsc` Ant task to the `build.xml` file, wrapped inside of the `build-service` target:

   ```
<target name="build-service">
   <jwsc
      srcdir="src"
      destdir="output/ComplexServiceEar" >
      <jws file="examples/webservices/complex/ComplexImpl.java"
         type="JAXRPC">
        <WLHttpTransport
           contextPath="complex" serviceUri="ComplexService"
           portName="ComplexServicePort"/>
      </jws>
   </jwsc>
</target>
   ```

In the preceding example:
The type attribute of the `<jws>` element specifies the type of Web service (JAX-WS or JAX-RPC).

The `<WLHttpTransport>` child element of the `<jws>` element of the jwsc Ant task specifies the context path and service URI sections of the URL used to invoke the Web service over the HTTP/S transport, as well as the name of the port in the generated WSDL. This value overrides the value specified in the JWS file using the `@WLHttpTransport` attribute. For more information about defining the context path, see "Defining the Context Path of a WebLogic Web Service" in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server.

10. Execute the jwsc Ant task:

```prompt> ant build-service```

See the output/ComplexServiceEar directory to view the files and artifacts generated by the jwsc Ant task.

11. Start the WebLogic Server instance to which the Web service will be deployed.

12. Deploy the Web service, packaged in the ComplexServiceEar Enterprise Application, to WebLogic Server, using either the Administration Console or the wldeploy Ant task. For example:

```prompt> ant deploy```

13. Deploy the Web service, packaged in an Enterprise Application, to WebLogic Server, using either the Administration Console or the wldeploy Ant task. In either case, you deploy the ComplexServiceEar Enterprise application, located in the output directory.

To use the wldeploy Ant task, add the following target to the build.xml file:

```xml
<taskdef name="wldeploy" classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="deploy">
  <wldeploy action="deploy"
    name="ComplexServiceEar" source="output/ComplexServiceEar"
    user="${wls.username}" password="${wls.password}"
    verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}"
    targets="${wls.server.name}" />
</target>
```

Substitute the values for wls.username, wls.password, wls.hostname, wls.port, and wls.server.name that correspond to your WebLogic Server instance.

14. Test that the Web service is deployed correctly by invoking its WSDL in your browser:

```http://host:port/complex/ComplexService?WSDL```

To run the Web service, you need to create a client that invokes it. See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a Web service.
2.2.1 Sample BasicStruct JavaBean

```java
package examples.webservices.complex;

/**
 * Defines a simple JavaBean called BasicStruct that has integer, String,
 * and String[] properties
 */
public class BasicStruct {
  // Properties
  private int intValue;
  private String stringValue;
  private String[] stringArray;

  // Getter and setter methods
  public int getIntValue() {
    return intValue;
  }
  public void setIntValue(int intValue) {
    this.intValue = intValue;
  }
  public String getStringValue() {
    return stringValue;
  }
  public void setStringValue(String stringValue) {
    this.stringValue = stringValue;
  }
  public String[] getStringArray() {
    return stringArray;
  }
  public void setStringArray(String[] stringArray) {
    this.stringArray = stringArray;
  }
  public String toString() {
    return "IntValue=", intValue, "StringValue=", stringValue;
  }
}
```

2.2.2 Sample ComplexImpl.java JWS File

```java
package examples.webservices.complex;
import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.jws.soap.SOAPBinding;
import weblogic.jws.WLHttpTransport;
import examples.webservices.complex.BasicStruct;

@WebService(serviceName="ComplexService", name="ComplexPortType",

targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
targetNamespace="http://example.org")
@WebService(serviceName="ComplexPortType", name="ComplexPortType",
```
// WebLogic-specific JWS annotation that specifies the context path and service
// URI used to build the URI of the Web Service is "complex/ComplexService"
@WLHttpTransport(contextPath="complex", serviceUri="ComplexService",
portName="ComplexServicePort")
/**
 * This JWS file forms the basis of a WebLogic Web Service. The Web Services
 * has two public operations:
 *  - echoInt(int)
 *  - echoComplexType(BasicStruct)
 *
 * The Web Service is defined as a "document-literal" service, which means
 * that the SOAP messages have a single part referencing an XML Schema element
 * that defines the entire body.
 */
public class ComplexImpl {

    // Standard JWS annotation that specifies that the method should be exposed
    // as a public operation. Because the annotation does not include the
    // member-value 'operationName', the public name of the operation is the
    // same as the method name: echoInt.
    //
    // The WebResult annotation specifies that the name of the result of the
    // operation in the generated WSDL is "IntegerOutput", rather than the
    // default name 'return'. The WebParam annotation specifies that the input
    // parameter name in the WSDL file is "IntegerInput" rather than the Java
    // name of the parameter, "input".
    @WebMethod()
    @WebResult(name="IntegerOutput",
        targetNamespace="http://example.org/complex")
    public int echoInt(
        @WebParam(name="IntegerInput",
        targetNamespace="http://example.org/complex")
        int input)
    {
        System.out.println("echoInt " + input + " to you too!");
        return input;
    }

    // Standard JWS annotation to expose method "echoStruct" as a public operation
    // called 'echoComplexType'
    // The WebResult annotation specifies that the name of the result of the
    // operation in the generated WSDL is "EchoStructReturnMessage",
    // rather than the default name "return".
    @WebMethod(operationName="echoComplexType")
    @WebResult(name="EchoStructReturnMessage",
        targetNamespace="http://example.org/complex")
    public BasicStruct echoStruct(BasicStruct struct)
    {
        System.out.println("echoComplexType called");
        return struct;
    }
}

2.2.3 Sample Ant Build File for ComplexImpl.java JWS File

The following build.xml file uses properties to simplify the file.

    <project name="webservices-complex" default="all">
    <!-- set global properties for this build -->
    <property name="wls.username" value="weblogic" />

Use Cases and Examples  2-9
<property name="wls.password" value="weblogic" />
<property name="wls.hostname" value="localhost" />
<property name="wls.port" value="7001" />
<property name="wls.server.name" value="myserver" />
<property name="ear.deployed.name" value="complexServiceEAR" />
<property name="example-output" value="output" />
<property name="ear.dir" value="${example-output}/complexServiceEar" />
<property name="clientclass-dir" value="${example-output}/clientclass" />
<path id="client.class.path">
  <pathelement path="${clientclass-dir}"/>
  <pathelement path="${java.class.path}"/>
</path>
<taskdef name="jwsc"
  classname="weblogic.wsee.tools.anttasks.JwscTask" />
<taskdef name="clientgen"
  classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
<taskdef name="wldeploy"
  classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="all" depends="clean,build-service,deploy,client"/>
<target name="clean" depends="undeploy">
  <delete dir="${example-output}"/>
</target>
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="${ear-dir}" keepGenerated="true"
  >
    <jws file="examples/webservices/complex/ComplexImpl.java"
      type="JAXRPC">
      <WLHttpTransport
        contextPath="complex" serviceUri="ComplexService"
        portName="ComplexServicePort"/>
    </jws>
  </jwsc>
</target>
<target name="deploy">
  <wldeploy action="deploy"
    name="${ear.deployed.name}" source="${ear-dir}" user="${wls.username}" password="${wls.password}" verbose="true" adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}"/>
</target>
<target name="undeploy">
  <wldeploy action="undeploy" failonerror="false"
    name="${ear.deployed.name}" user="${wls.username}" password="${wls.password}" verbose="true" adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}"/>
</target>
<target name="client">
  <clientgen
    wsd1="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="${clientclass-dir}" packageName="examples.webservices.complex.client"
    type="JAXRPC"/>
  <javac
    srcdir="${clientclass-dir}" destdir="${clientclass-dir}" includes="**/*.java"/>
2.3 Creating a Web Service from a WSDL File

Another common use case of creating a Web service is to start from an existing WSDL file, often referred to as the golden WSDL. A WSDL file is a public contract that specifies what the Web service looks like, such as the list of supported operations, the signature and shape of each operation, the protocols and transports that can be used when invoking the operations, and the XML Schema data types that are used when transporting the data. Based on this WSDL file, you generate the artifacts that implement the Web service so that it can be deployed to WebLogic Server. You use the wsdlc Ant task to generate the following artifacts.

- JWS service endpoint interface (SEI) that implements the Web service described by the WSDL file.
- JWS implementation file that contains a partial (stubbed-out) implementation of the generated JWS SEI. This file must be customized by the developer.
- Data binding artifacts used by WebLogic Server to convert between the XML and Java representations of the Web service parameters and return values.
- Optional Javadoc for the generated JWS SEI.

Note: The only file generated by the wsdlc Ant task that you update is the JWS implementation file. You never need to update the JAR file that contains the JWS SEI and data binding artifacts.

Typically, you run the wsdlc Ant task one time to generate a JAR file that contains the generated JWS SEI file and data binding artifacts, then code the generated JWS file that implements the interface, adding the business logic of your Web service. In particular, you add Java code to the methods that implement the Web service operations so that the operations behave as needed and add additional JWS annotations.

After you have coded the JWS implementation file, you run the jwsc Ant task to generate the deployable Web service, using the same steps as described in the preceding sections. The only difference is that you use the compiledWsdl attribute to specify the JAR file (containing the JWS SEI file and data binding artifacts) generated by the wsdlc Ant task.

The following simple example shows how to create a Web service from the WSDL file shown in Section 2.3.1, “Sample WSDL File.” The Web service has one operation, getTemp, that returns a temperature when passed a zip code.
1. Set your WebLogic Server environment.

Open a command window and execute the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the `bin` subdirectory of your domain directory. The default location of WebLogic Server domains is `MW_HOME/user_projects/domains/domainName`, where `MW_HOME` is the top-level installation directory of the Oracle products and `domainName` is the name of your domain.

2. Create a working directory:

```
prompt> mkdir /myExamples/wsdlc
```

3. Put your WSDL file into an accessible directory on your computer.

For the purposes of this example, it is assumed that your WSDL file is called `TemperatureService.wsdl` and is located in the `/myExamples/wsdlc/wsdl_files` directory. See Section 2.3.1, "Sample WSDL File" for a full listing of the file.

4. Create a standard Ant `build.xml` file in the project directory and add a `taskdef` Ant task to specify the full Java classname of the `wsdlc` task:

```
<project name="webservices-wsdlc" default="all">
<taskdef name="wsdlc" class="weblogic.wsee.tools.anttasks.WsdlcTask"/>
</project>
```

See Section 2.3.3, "Sample Ant Build File for TemperatureService" for a full sample `build.xml` file that contains additional targets from those described in this procedure, such as `clean`, `undeploy`, `client`, and `run`. The full `build.xml` file also uses properties, such as `${ear-dir}`, rather than always using the hard-coded name for the EAR directory.

5. Add the following call to the `wsdlc` Ant task to the `build.xml` file, wrapped inside of the `generate-from-wsdl` target:

```
<target name="generate-from-wsdl">
<wsdlc>
  <srcWsdl>"wsdl_files/TemperatureService.wsdl"</srcWsdl>
  <destJwsDir>"output/compiledWsdl"</destJwsDir>
  <destImplDir>"output/impl"</destImplDir>
  <packageName>"examples.webservices.wsdlc"</packageName>
</wsdlc>
</target>
```

The `wsdlc` task in the examples generates the JAR file that contains the JWS SEI and data binding artifacts into the `output/compiledWsdl` directory under the current directory. It also generates a partial implementation file (`TemperaturePortTypeImpl.java`) of the JWS SEI into the `output/impl/examples/webservices/wsdlc` directory (which is a combination of the output directory specified by `destImplDir` and the directory hierarchy specified by the package name). All generated JWS files will be packaged in the `examples.webservices.wsdlc` package.

6. Execute the `wsdlc` Ant task by specifying the `generate-from-wsdl` target at the command line:

```
prompt> ant generate-from-wsdl
```

See the output directory if you want to examine the artifacts and files generated by the `wsdlc` Ant task.

7. Update the generated

```
output/impl/examples/webservices/wsdlc/TemperaturePortTypeImpl.java
```
JWS implementation file using your favorite Java IDE or text editor to add Java code to the methods so that they behave as you want.

See Section 2.3.2, "Sample TemperaturePortType Java Implementation File" for an example; the added Java code is in bold. The generated JWS implementation file automatically includes values for the @WebService and @WLHttpTransport JWS annotations that correspond to the values in the original WSDL file.

**Note:** There are restrictions on the JWS annotations that you can add to the JWS implementation file in the "starting from WSDL" use case. See "wsdlc" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for details.

For simplicity, the sample getTemp() method in TemperaturePortTypeImpl.java returns a hard-coded number. In real life, the implementation of this method would actually look up the current temperature at the given zip code.

8. Copy the updated TemperaturePortTypeImpl.java file into a permanent directory, such as a src directory under the project directory; remember to create child directories that correspond to the package name:

   prompt> cd /examples/wsdlc
   prompt> mkdir src/examples/webservices/wsdlc
   prompt> cp output/impl/examples/webservices/wsdlc/TemperaturePortTypeImpl.java
                  src/examples/webservices/wsdlc/TemperaturePortTypeImpl.java

9. Add a build-service target to the build.xml file that executes the jwsc Ant task against the updated JWS implementation class. Use the compiledWsdl attribute of jwsc to specify the name of the JAR file generated by the wsdlc Ant task:

   ```xml
   <taskdef name="jwsc" classname="weblogic.wsee.tools.anttasks.JwscTask" />
   <target name="build-service">
     <jwsc
       srcdir="src"
       destdir="${ear-dir}"
     >
       <jws
         file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java"
         type="JAXRPC">
         <WLHttpTransport
           contextPath="temp" serviceUri="TemperatureService"
           portName="TemperaturePort">
         </WLHttpTransport>
       </jws>
     </jwsc>
   </target>
   ```

   In the preceding example:
   - The type attribute of the <jws> element specifies the type of Web services (JAX-WS or JAX-RPC).
   - The <WLHttpTransport> child element of the <jws> element of the jwsc Ant task specifies the context path and service URI sections of the URL used to invoke the Web service over the HTTP/S transport, as well as the name of the port in the generated WSDL. This value overrides the value specified in the JWS file using the @WLHttpTransport attribute.
10. Execute the `build-service` target to generate a deployable Web service:

```prompt> ant build-service```

You can re-run this target if you want to update and then re-build the JWS file.

11. Start the WebLogic Server instance to which the Web service will be deployed.

12. Deploy the Web service, packaged in an Enterprise Application, to WebLogic Server, using either the Administration Console or the `wldeploy` Ant task. In either case, you deploy the `wsdlcEar` Enterprise application, located in the output directory.

To use the `wldeploy` Ant task, add the following target to the `build.xml` file:

```xml
<taskdef name="wldeploy" class="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="deploy">
  <wldeploy action="deploy" name="wsdlcEar"
    source="output/wsdlcEar" user="${wls.username}" password="${wls.password}" verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
</target>
```

Substitute the values for `wls.username`, `wls.password`, `wls.hostname`, `wls.port`, and `wls.server.name` that correspond to your WebLogic Server instance.

Deploy the WAR file by executing the `deploy` target:

```prompt> ant deploy```

13. Test that the Web service is deployed correctly by invoking its WSDL in your browser:

```http://host:port/temp/TemperatureService?WSDL```

The context path and service URI section of the preceding URL are specified by the original golden WSDL. Use the hostname and port relevant to your WebLogic Server instance. Note that the deployed and original WSDL files are the same, except for the host and port of the endpoint address.

You can use the `clean`, `build-service`, `undeploy`, and `deploy` targets in the `build.xml` file to iteratively update, rebuild, undeploy, and redeploy the Web service as part of your development process.

To run the Web service, you need to create a client that invokes it. See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a Web service.

### 2.3.1 Sample WSDL File

```xml
<?xml version="1.0"?>
<definitions name="TemperatureService"
  targetNamespace="http://www.xmethods.net/sd/TemperatureService.wsdl"
  xmlns:tns="http://www.xmethods.net/sd/TemperatureService.wsdl"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:soap="http://schemas.xmlsoap.org/soap/"
  xmlns="http://schemas.xmlsoap.org/soap/">
  <message name="getTempRequest">
    <part name="zip" type="xsd:string"/>
  </message>
</definitions>
```
2.3.2 Sample TemperaturePortType Java Implementation File

```java
package examples.webservices.wsdlc;
import javax.jws.WebService;
import weblogic.jws.*;

/**
 * TemperaturePortTypeImpl class implements web service endpoint
 * interface TemperaturePortType */
@WebService(
    serviceName="TemperatureService",
    targetNamespace="http://www.xmethods.net/sd/TemperatureService.wsdl"
)
@WLHttpTransport(
    contextPath="temp",
    serviceUri="TemperatureService",
    portName="TemperaturePort")
public class TemperaturePortTypeImpl implements examples.webservices.wsdlc.TemperaturePortType {
    public TemperaturePortTypeImpl() { }
    public float getTemp(java.lang.String zip) {
        return 1.234f;
    }
}
```
2.3.3 Sample Ant Build File for TemperatureService

The following build.xml file uses properties to simplify the file.

```xml
<project default="all">
<!-- set global properties for this build -->
<property name="wls.username" value="weblogic" />
<property name="wls.password" value="weblogic" />
<property name="wls.hostname" value="localhost" />
<property name="wls.port" value="7001" />
<property name="wls.server.name" value="myserver" />
<property name="ear.deployed.name" value="wsdlcEar" />
<property name="example-output" value="output" />
<property name="compiledWsdl-dir" value="${example-output}/compiledWsdl" />
<property name="impl-dir" value="${example-output}/impl" />
<property name="ear-dir" value="${example-output}/wsdlcEar" />
<property name="clientclass-dir" value="${example-output}/clientclasses" />

<path id="client.class.path">
  <pathelement path="${clientclass-dir}"/>
  <pathelement path="${java.class.path}"/>
</path>
	<taskdef name="wsdlc"classname="weblogic.wsee.tools.anttasks.WsdlcTask"/> 
	<taskdef name="jwsc"classname="weblogic.wsee.tools.anttasks.JwscTask"/> 
	<taskdef name="clientgen"classname="weblogic.wsee.tools.anttasks.ClientGenTask"/> 
	<taskdef name="wldeploy"classname="weblogic.ant.taskdefs.management.WLDeploy"/>
	<target name="all" 
depends="clean,generate-from-wsdl,build-service,deploy,client" />
	<target name="clean" depends="undeploy">
    <delete dir="${example-output}"/>
</target>
	<target name="generate-from-wsdl">
    <wsdlc 
        srcWsdl="wsdl_files/TemperatureService.wsdl" 
        destJwsDir="${compiledWsdl-dir}" 
        destImplDir="${impl-dir}" 
        packageName="examples.webservices.wsdlc" />
</target>
	<target name="build-service">
    <jwsc 
        srcdir="src" 
        destdir="${ear-dir}">/
        <jws file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java" 
            compiledWsdl="${compiledWsdl-dir}/TemperatureService.wsdl" 
            type="JAXRPC"> 
            <WLHttpTransport 
                contextPath="temp" serviceUri="TemperatureService" 
                portName="TemperaturePort"/>
        </jws>
    </jwsc>
</target>
	<target name="deploy">
    <wldeploy action="deploy" name="${ear.deployed.name}" 
        source="${ear-dir}" user="${wls.username}" 
```
password='${wls.password}' verbose='true'
adminurl='t3://${wls.hostname}:${wls.port}'
targets='${wls.server.name}' />
</target>
<target name='undeploy'>
<wldeploy action='undeploy' name='${ear.deployed.name}"
failonerror='false'
user='${wls.username}' password='${wls.password}' verbose='true'
adminurl='t3://${wls.hostname}:${wls.port}'
targets='${wls.server.name}' />
</target>
<target name='client'>
<clientgen
wsdl='http://${wls.hostname}:${wls.port}/temp/TemperatureService?WSDL'
destDir='${clientclass-dir}'
packageName='examples.webservices.wsdlc.client'
type='JAXRPC'>
</clientgen>
<javac
srcdir='${clientclass-dir}' destdir='${clientclass-dir}'
includes='**/*.java'/>
<javac
srcdir='src destdir='${clientclass-dir}'
includes='examples/webservices/wsdlc/client/**/*.java'/>
</target>
<target name='run'>
<java classname='examples.webservices.wsdlc.client.TemperatureClient'
fork='true' failonerror='true' >
<classpath refid='client.class.path'/>
<arg
line='http://${wls.hostname}:${wls.port}/temp/TemperatureService' />
</java>
</target>
</project>

2.4 Invoking a Web Service from a Java SE Client

**Note:** As described in this section, you can invoke a Web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for stand-alone Java applications that are running in an environment where WebLogic Server libraries are not available, see Section 6.4, "Using a Stand-Alone Client JAR File When Invoking Web Services".

When you invoke an operation of a deployed Web service from a client application, the Web service could be deployed to WebLogic Server or to any other application server, such as .NET. All you need to know is the URL to its public contract file, or WSDL.

In addition to writing the Java client application, you must also run the **clientgen** WebLogic Web service Ant task to generate the artifacts that your client application needs to invoke the Web service operation. These artifacts include:

- The Java class for the JAX-RPC **Stub** and **Service** interface implementations for the particular Web service you want to invoke.
The Java class for any user-defined XML Schema data types included in the WSDL file.

The JAX-RPC mapping deployment descriptor file which contains information about the mapping between the Java user-defined data types and their corresponding XML Schema types in the WSDL file.

A client-side copy of the WSDL file.

The following example shows how to create a Java client application that invokes the echoComplexType operation of the ComplexService WebLogic Web service described in Section 2.2, "Creating a Web Service With User-Defined Data Types." The echoComplexType operation takes as both a parameter and return type the BasicStruct user-defined data type.

**Note:** It is assumed in this procedure that you have created and deployed the ComplexService Web service.

1. Set your WebLogic Server environment.

   Open a command window and execute the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is $MW_HOME/user_projects/domains/domainName, where $MW_HOME is the top-level installation directory of the Oracle products and domainName is the name of your domain.

2. Create a project directory:

   ```
   prompt> mkdir /myExamples/simple_client
   ```

3. Create a src directory under the project directory, as well as subdirectories that correspond to the package name of the Java client application (shown later on in this procedure):

   ```
   prompt> cd /myExamples/simple_client
   prompt> mkdir src/examples/webservices/simple_client
   ```

4. Create a standard Ant build.xml file in the project directory and add a taskdef Ant task to specify the full Java classname of the clientgen task:

   ```
   <project name="webservices-simple_client" default="all">
   <taskdef name="clientgen" class="weblogic.wsee.tools.anttasks.ClientGenTask" />
   </project>
   ```

   See Section 2.4.2, "Sample Ant Build File For Building Java Client Application" for a full sample build.xml file. The full build.xml file uses properties, such as $clientclass-dir, rather than always using the hard-coded name output directory for client classes.

5. Add the following calls to the clientgen and javac Ant tasks to the build.xml file, wrapped inside of the build-client target:

   ```
   <target name="build-client">
   <clientgen
       wdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
       destDir="output/clientclass"
       packageName="examples.webservices.simple_client"
       type="JAXRPC"/>
   <javac
   ```
The clientgen Ant task uses the WSDL of the deployed ComplexService Web service to generate the necessary artifacts and puts them into the output/clientclass directory, using the specified package name. Replace the variables with the actual hostname and port of your WebLogic Server instance that is hosting the Web service.

The clientgen Ant task also automatically generates the examples.webservices.complex.BasicStruct JavaBean class, which is the Java representation of the user-defined data type specified in the WSDL.

The build-client target also specifies the standard javac Ant task, in addition to clientgen, to compile all the Java code, including the simple Java program described in the next step, into class files.

The clientgen Ant task also provides the destFile attribute if you want the Ant task to automatically compile the generated Java code and package all artifacts into a JAR file. For details and an example, see "clientgen" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server.

6. Create the Java client application file that invokes the echoComplexType operation.

Open your favorite Java IDE or text editor and create a Java file called Main.java using the code specified in Section 2.4.1, "Sample Java Client Application."

The Main client application takes a single argument: the WSDL URL of the Web service. The application then follows standard JAX-RPC guidelines to invoke an operation of the Web service using the Web service-specific implementation of the Service interface generated by clientgen. The application also imports and uses the BasicStruct user-defined type, generated by the clientgen Ant task, that is used as a parameter and return value for the echoStruct operation. For details, see Chapter 6, "Invoking Web Services."

7. Save the Main.java file in the src/examples/webservices/simple_client subdirectory of the main project directory.

8. Execute the clientgen and javac Ant tasks by specifying the build-client target at the command line:

   prompt> ant build-client

   See the output/clientclass directory to view the files and artifacts generated by the clientgen Ant task.

9. Add the following targets to the build.xml file, used to execute the Main application:

   ```xml
   <path id="client.class.path">
     <pathelement path="output/clientclass"/>
     <pathelement path="${java.class.path}"/>
   </path>
   <target name="run"">
     <java fork="true">
       <classpath>
         <pathelement path="output/clientclass"/>
         <pathelement path="${java.class.path}"/>
       </classpath>
       <classpath>
         <pathelement path="examples/webservices/simple_client"/>
       </classpath>
       <classpath>
         <pathelement path="output/clientclass"/>
       </classpath>
       <classpath>
         <pathelement path="${java.class.path}"/>
       </classpath>
       <classpath>
         <pathelement path="examples/webservices/simple_client"/>
       </classpath>
       <classpath>
         <pathelement path="output/clientclass"/>
       </classpath>
       <classpath>
         <pathelement path="${java.class.path}"/>
       </classpath>
       <classpath>
         <pathelement path="examples/webservices/simple_client"/>
       </classpath>
       <classpath>
         <pathelement path="output/clientclass"/>
       </classpath>
       <classpath>
         <pathelement path="${java.class.path}"/>
       </classpath>
       <classpath>
         <pathelement path="examples/webservices/simple_client"/>
       </classpath>
       <classpath>
         <pathelement path="output/clientclass"/>
       </classpath>
       <classpath>
         <pathelement path="${java.class.path}"/>
       </classpath>
       <classpath>
         <pathelement path="examples/webservices/simple_client"/>
       </classpath>
       <classpath>
         <pathelement path="output/clientclass"/>
       </classpath>
       <classpath>
         <pathelement path="${java.class.path}"/>
       </classpath>
       </java>
   </target>
   ```
<classpath refid="client.class.path"/>
<arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService" />
</java>
</target>

The run target invokes the Main application, passing it the WSDL URL of the deployed Web service as its single argument. The classpath element adds the clientclass directory to the CLASSPATH, using the reference created with the <path> task.

10. Execute the run target to invoke the echoComplexType operation:

   prompt> ant run

   If the invoke was successful, you should see the following final output:

   run:
   [java] echoComplexType called. Result: 999, Hello Struct

You can use the build-client and run targets in the build.xml file to iteratively update, rebuild, and run the Java client application as part of your development process.

2.4.1 Sample Java Client Application

The following provides a simple Java client application that invokes the echoComplexType operation.

```
package examples.webservices.simple_client;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
// import the BasicStruct class, used as a param and return value of the
// echoComplexType operation. The class is generated automatically by
// the clientgen Ant task.
import examples.webservices.complex.BasicStruct;
/**
 * This is a simple Java client application that invokes the
 * echoComplexType operation of the ComplexService Web service.
 */
public class Main {
    public static void main(String[] args)
        throws ServiceException, RemoteException {
        ComplexService service = new ComplexService_Impl (args[0] + "?WSDL" );
        ComplexPortType port = service.getComplexServicePort();
        BasicStruct in = new BasicStruct();
        in.setIntValue(999);
        in.setStringValue("Hello Struct");
        BasicStruct result = port.echoComplexType(in);
        System.out.println("echoComplexType called. Result: " + result.getIntValue() + ", " + result.getStringValue());
    }
}
```

2.4.2 Sample Ant Build File For Building Java Client Application

The following build.xml file defines tasks to build the Java client application. The example uses properties to simplify the file.

```
<project name="webservices-simple_client" default="all">
    <!-- set global properties for this build -->
```
You can also invoke a Web service (WebLogic, .NET, and so on) from within a deployed WebLogic Web service.

The procedure for invoking a Web service from a WebLogic Web service is similar to that described in Section 2.4, "Invoking a Web Service from a Java SE Client" except that instead of running the clientgen Ant task to generate the client stubs, you use the `<clientgen>` child element of `<jws>`, inside of the `jwsc` Ant task. The `jwsc` Ant task automatically packages the generated client stubs in the invoking Web service WAR file so that the Web service has immediate access to them. You then follow standard JAX-RPC programming guidelines in the JWS file that implements the Web service that invokes the other Web service.

The following example shows how to write a JWS file that invokes the `echoComplexType` operation of the `ComplexService` Web service described in Section 2.2, "Creating a Web Service With User-Defined Data Types."

**Note:** It is assumed that you have successfully deployed the `ComplexService` Web service.
1. Set your WebLogic Server environment.
   Open a command window and execute the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the `bin` subdirectory of your domain directory. The default location of WebLogic Server domains is `MW_HOME/user_projects/domains/domainName`, where `MW_HOME` is the top-level installation directory of the Oracle products and `domainName` is the name of your domain.

2. Create a project directory:
   ```
   prompt> mkdir /myExamples/service_to_service
   ```

3. Create a `src` directory under the project directory, as well as subdirectories that correspond to the package name of the JWS and client application files (shown later on in this procedure):
   ```
   prompt> cd /myExamples/service_to_service
   prompt> mkdir src/examples/webservices/service_to_service
   ```

4. Create the JWS file that implements the Web service that invokes the ComplexService Web service.
   Open your favorite Java IDE or text editor and create a Java file called `ClientServiceImpl.java` using the Java code specified in Section 2.5.1, "Sample ClientServiceImpl.java JWS File."

   The sample JWS file shows a Java class called `ClientServiceImpl` that contains a single public method, `callComplexService()`. The Java class imports the JAX-RPC stubs, generated later on by the `jwsc` Ant task, as well as the `BasicStruct` Java Bean (also generated by `clientgen`), which is the data type of the parameter and return value of the `echoComplexType` operation of the ComplexService Web service.

   The `ClientServiceImpl` Java class defines one method, `callComplexService()`, which takes two parameters: a `BasicStruct` which is passed on to the `echoComplexType` operation of the ComplexService Web service, and the URL of the ComplexService Web service. The method then uses the standard JAX-RPC APIs to get the `Service` and `PortType` of the ComplexService, using the stubs generated by `jwsc`, and then invokes the `echoComplexType` operation.

5. Save the `ClientServiceImpl.java` file in the `src/examples/webservices/service_to_service` directory.

6. Create a standard Ant `build.xml` file in the project directory and add the following task:
   ```
   <project name="webservices-service_to_service" default="all">
   <taskdef name="jwsc" classname="weblogic.wsee.tools.anttasks.JwscTask"/>
   </project>
   ```

   The `taskdef` task defines the full classname of the `jwsc` Ant task.

   See Section 2.5.2, "Sample Ant Build File For Building ClientService" for a full sample `build.xml` file that contains additional targets from those described in this procedure, such as `clean`, `deploy`, `undeploy`, `client`, and `run`. The full `build.xml` file also uses properties, such as `${ear-dir}`, rather than always using the hard-coded name for the EAR directory.

7. Add the following call to the `jwsc` Ant task to the `build.xml` file, wrapped inside of the `build-service` target:
   ```
   <target name="build-service">
   ```
In the preceding example, the <clientgen> child element of the <jws> element of the jwsc Ant task specifies that, in addition to compiling the JWS file, jwsc should also generate and compile the client artifacts needed to invoke the Web service described by the WSDL file.

In this example, the package name is set to examples.webservices.complex, which is different from the client application package name, examples.webservices.simple_client. As a result, you need to import the appropriate class files in the client application:

```java
import examples.webservices.complex.BasicStruct;
import examples.webservices.complex.ComplexPortType;
import examples.webservices.complex.ComplexService;
```

If the package name is set to the same package name as the client application, the import calls would be optional.

8. Execute the jwsc Ant task by specifying the build-service target at the command line:

   prompt> ant build-service

9. Start the WebLogic Server instance to which you will deploy the Web service.

10. Deploy the Web service, packaged in an enterprise application, to WebLogic Server, using either the Administration Console or the wldeploy Ant task. In either case, you deploy the ClientServiceEar Enterprise application, located in the output directory.

To use the wldeploy Ant task, add the following target to the build.xml file:

```xml
<target name="deploy">
  <wldeploy action="deploy" name="ClientServiceEar" source="ClientServiceEar" user="${wls.username}" password="${wls.password}" verbose="true" adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
</target>
```

Substitute the values for wls.username, wls.password, wls.hostname, wls.port, and wls.server.name that correspond to your WebLogic Server instance.

Deploy the WAR file by executing the deploy target:
prompt> ant deploy

11. Test that the Web service is deployed correctly by invoking its WSDL in your browser:

http://host:port/ClientService/ClientService?WSDL

See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a Web service.

2.5.1 Sample ClientServiceImpl.java JWS File

The following provides a simple Web service client application that invokes the echoComplexType operation.

```java
package examples.webservices.service_to_service;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;
// Import the BasicStruct data type, generated by clientgen and used
// by the ComplexService Web Service
import examples.webservices.complex.BasicStruct;
// Import the JAX-RPC Stubs for invoking the ComplexService Web Service.
// Stubs generated by clientgen
import examples.webservices.service_to_service.ComplexPortType;
import examples.webservices.service_to_service.ComplexService_Impl;
import examples.webservices.service_to_service.ComplexService;
@WebService(name="ClientPortType", serviceName="ClientService",
targetNamespace="http://examples.org")
@WLHttpTransport(contextPath="ClientService", serviceUri="ClientService",
portName="ClientServicePort")
public class ClientServiceImpl {
    @WebMethod()
    public String callComplexService(BasicStruct input, String serviceUrl)
        throws ServiceException, RemoteException
    {
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePort();
        // Invoke the echoComplexType operation of ComplexService
        BasicStruct result = port.echoComplexType(input);
        System.out.println("Invoked ComplexPortType.echoComplexType.");
        return "Invoke went okay! Here's the result: ",
            " + result.getIntValue() + ",
            " + result.getStringValue() + ";
    }
}
```

2.5.2 Sample Ant Build File For Building ClientService

The following build.xml file defines tasks to build the client application. The example uses properties to simplify the file.

The following build.xml file uses properties to simplify the file.

```xml
<project name="webservices-service_to_service" default="all">
    <!-- set global properties for this build -->
    <property name="wls.username" value="weblogic" />
    <property name="wls.password" value="weblogic" />
</project>
```
<property name="wls.hostname" value="localhost"/>
<property name="wls.port" value="7001"/>
<property name="wls.server.name" value="myserver"/>
<property name="ear.deployed.name" value="ClientServiceEar"/>
<property name="example-output" value="output"/>
<property name="ear-dir" value="${example-output}/ClientServiceEar"/>
<property name="clientclass-dir" value="${example-output}/clientclasses"/>
<path id="client.class.path">
  <pathelement path="${clientclass-dir}"/>
  <pathelement path="${java.class.path}"/>
</path>
<taskdef name="jwsc"
classname="weblogic.wsee.tools.anttasks.JwscTask"/>
<taskdef name="clientgen"
classname="weblogic.wsee.tools.anttasks.ClientGenTask"/>
<taskdef name="wldeploy"
classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="all" depends="clean,build-service,deploy,client"/>
<target name="clean" depends="undeploy">
  <delete dir="${example-output}"/>
</target>
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="${ear-dir}" >
  <jws
    file="examples/webservices/service_to_service/ClientServiceImpl.java"
    type="JAXRPC">
    <WLHttpTransport
      contextPath="ClientService" serviceUri="ClientService"
      portName="ClientServicePort"/>
    <clientgen
      type="JAXRPC"
      wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
      packageName="examples.webservices.complex"/>
  </jws>
  </jwsc>
</target>
<target name="deploy">
  <wldeploy action="deploy" name="${ear.deployed.name}" source="${ear-dir}" user="${wls.username}" password="${wls.password}" verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}"/>
</target>
<target name="undeploy">
  <wldeploy action="undeploy" name="${ear.deployed.name}" failonerror="false"
    user="${wls.username}" password="${wls.password}" verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}"/>
</target>
<target name="client">
  <clientgen
    wsdl="http://${wls.hostname}:${wls.port}/ClientService/ClientService?WSDL"
    destDir="${clientclass-dir}" packageNames="examples.webservices.service_to_service.client"
    type="JAXRPC"/>
  <javac
    srcdir="src"
    destdir="${clientclass-dir}"/>
</target>
<target name="build">
    <javac srcdir="src" destdir="${clientclass-dir}"
        includes="examples/webservices/service_to_service/client/**/*.java"/>
</target>

<target name="run">
    <java classname="examples.webservices.service_to_service.client.Main"
        fork="true" failonerror="true">
        <classpath refid="client.class.path"/>
        <arg line="http://${wls.hostname}:${wls.port}/ClientService/ClientService"/>
    </java>
</target>
</project>
This chapter describes the iterative development process for WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- Section 3.1, "Overview of the WebLogic Web Service Programming Model"
- Section 3.2, "Configuring Your Domain For Web Services Features"
- Section 3.3, "Developing WebLogic Web Services Starting From Java: Main Steps"
- Section 3.4, "Developing WebLogic Web Services Starting From a WSDL File: Main Steps"
- Section 3.5, "Creating the Basic Ant build.xml File"
- Section 3.6, "Running the jwsc WebLogic Web Services Ant Task"
- Section 3.7, "Running the wsdlc WebLogic Web Services Ant Task"
- Section 3.8, "Updating the Stubbed-out JWS Implementation Class File Generated By wsdlc"
- Section 3.9, "Deploying and Undeploying WebLogic Web Services"
- Section 3.10, "Browsing to the WSDL of the Web Service"
- Section 3.11, "Configuring the Server Address Specified in the Dynamic WSDL"
- Section 3.12, "Testing the Web Service"
- Section 3.13, "Integrating Web Services Into the WebLogic Split Development Directory Environment"

### 3.1 Overview of the WebLogic Web Service Programming Model

The WebLogic Web Services programming model centers around JWS files—Java files that use JWS annotations to specify the shape and behavior of the Web Service—and Ant tasks that execute on the JWS file. JWS annotations are based on the metadata feature, introduced in Version 5.0 of the JDK (specified by JSR-175 at [http://www.jcp.org/en/jsr/detail?id=175](http://www.jcp.org/en/jsr/detail?id=175)) and include standard annotations defined by Web Services Metadata for the Java Platform specification (JSR-181), described at [http://www.jcp.org/en/jsr/detail?id=181](http://www.jcp.org/en/jsr/detail?id=181), as well as additional ones. For a complete list of JWS annotations that are supported, see "Web Service Annotation Support" in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server. For additional detailed information about this programming model, see "Anatomy of a WebLogic Web Service" in Oracle Fusion Middleware Introducing WebLogic Web Services for Oracle WebLogic Server.
The following sections describe the high-level steps for iteratively developing a Web Service, either starting from Java or starting from an existing WSDL file:

- **Section 3.3, "Developing WebLogic Web Services Starting From Java: Main Steps"**
- **Section 3.4, "Developing WebLogic Web Services Starting From a WSDL File: Main Steps"**

Iterative development refers to setting up your development environment in such a way so that you can repeatedly code, compile, package, deploy, and test a Web Service until it works as you want. The WebLogic Web Service programming model uses Ant tasks to perform most of the steps of the iterative development process. Typically, you create a single `build.xml` file that contains targets for all the steps, then repeatedly run the targets, after you have updated your JWS file with new Java code, to test that the updates work as you expect.

In addition to the command-line tools described in this section, you can use an IDE, such as Oracle JDeveloper, to develop Web services. For more information, see "Using Oracle IDEs to Build Web Services" in Oracle Fusion Middleware Introducing WebLogic Web Services for Oracle WebLogic Server.

### 3.2 Configuring Your Domain For Web Services Features

After you have created a WebLogic Server domain, you can use the Configuration Wizard to update the domain, using a Web Services-specific extension template, so that the resources required by certain WebLogic Web Services features are automatically configured. Although use of this extension template is not required, it makes the configuration of JMS and JDBC resources much easier.

The Web Services extension template automatically configures the resources required for the following features:

- Web Services Reliable Messaging
- Buffering
- JMS Transport

---

**Note:** A domain that does not contain Web Services resources will still boot and operate correctly for non-Web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for Web services has not been completely deployed.

---

The following procedures describe how to create and extend a domain so that it is automatically configured for the advanced Web services features. For detailed instructions about using the Configuration Wizard to create and update WebLogic Server domains, see Oracle WebLogic Server Creating WebLogic Domains Using the Configuration Wizard.

To create a domain that is automatically configured for the advanced Web service features:

1. Start the Configuration Wizard.
2. In the Welcome window, select **Create a new WebLogic domain**.
3. Click **Next**.
4. Select Generate a domain configured automatically to support the following products and select WebLogic Advanced Web Services for JAX-RPC Extension.
5. Click Next.
6. Enter the name and location of the domain and click Next.
7. Configure the administrator user name and password and click Next.
8. Configure the server start mode and JDK and click Next.
9. If you want to further configure the JMS services, file stores, or any other feature, select the items on the Select Optional Configuration screen. This is not typical. Otherwise, leave all items deselected and click Next.
10. When you reach the Configuration Summary screen, verify the domain details and click Create.
11. Click Done to exit.

To extend an existing domain so that it is automatically configured for these Web Services features:

1. Start the Configuration Wizard.
2. In the Welcome window, select Extend an Existing WebLogic Domain.
3. Click Next.
4. Select the domain to which you want to apply the extension template.
5. Click Next.
6. Select Extend my domain automatically to support the following added products and select WebLogic Advanced Web Services for JAX-RPC Extension.
7. Click Next.
8. If you want to further configure the JMS services or file stores, select the items on the Select Optional Configuration screen. This is not typical. Otherwise, leave all items deselected and click Next.
9. Verify that you are extending the correct domain, then click Extend.
10. Click Done to exit.

### 3.3 Developing WebLogic Web Services Starting From Java: Main Steps

This section describes the general procedure for developing WebLogic Web Services starting from Java—in effect, coding the JWS file from scratch and later generating the WSDL file that describes the service. See Chapter 2, "Use Cases and Examples" for specific examples of this process.

The following procedure is just a recommendation; if you have set up your own development environment, you can use this procedure as a guide for updating your existing environment to develop WebLogic Web Services.

**Note:** This procedure does not use the WebLogic Web Services split development directory environment. If you are using this development environment, and would like to integrate Web Services development into it, see Section 3.13, "Integrating Web Services Into the WebLogic Split Development Directory Environment" for details.
### 3.4 Developing WebLogic Web Services Starting From a WSDL File: Main Steps

This section describes the general procedure for developing WebLogic Web Services based on an existing WSDL file. See Chapter 3, "Developing WebLogic Web Services" for a specific example of this process.

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set up the environment.</td>
<td>Open a command window and execute the <code>setDomainEnv.cmd</code> (Windows) or <code>setDomainEnv.sh</code> (UNIX) command, located in the <code>bin</code> subdirectory of your domain directory. The default location of WebLogic Server domains is <code>$MW_HOME/user_projects/domains/domainName</code>, where <code>$MW_HOME</code> is the top-level installation directory of the Oracle products and <code>domainName</code> is the name of your domain.</td>
</tr>
<tr>
<td>2</td>
<td>Create a project directory.</td>
<td>The project directory will contain the JWS file, Java source for any user-defined data types, and the Ant <code>build.xml</code> file. You can name the project directory anything you want.</td>
</tr>
<tr>
<td>3</td>
<td>Create the JWS file that implements the Web Service.</td>
<td>See Section 4.3, &quot;Programming the JWS File: Typical Steps.&quot;</td>
</tr>
<tr>
<td>4</td>
<td>Create user-defined data types. (Optional)</td>
<td>If your Web Service uses user-defined data types, create the JavaBeans that describes them. See Section 4.6, &quot;Programming the User-Defined Java Data Type.&quot;</td>
</tr>
<tr>
<td>5</td>
<td>Create a basic Ant build file, <code>build.xml</code>.</td>
<td>See Section 3.5, &quot;Creating the Basic Ant build.xml File.&quot;</td>
</tr>
<tr>
<td>6</td>
<td>Run the <code>jwsc</code> Ant task against the JWS file.</td>
<td>The <code>jwsc</code> Ant task generates source code, data binding artifacts, deployment descriptors, and so on, into an output directory. The <code>jwsc</code> Ant task generates an Enterprise application directory structure at this output directory; later you deploy this exploded directory to WebLogic Server as part of the iterative development process. See Section 3.6, &quot;Running the jwsc WebLogic Web Services Ant Task.&quot;</td>
</tr>
<tr>
<td>7</td>
<td>Deploy the Web Service to WebLogic Server.</td>
<td>See Section 3.9, &quot;Deploying and Undeploying WebLogic Web Services.&quot;</td>
</tr>
<tr>
<td>8</td>
<td>Browse to the WSDL of the Web Service.</td>
<td>Browse to the WSDL of the Web Service to ensure that it was deployed correctly. See Section 3.10, &quot;Browsing to the WSDL of the Web Service.&quot;</td>
</tr>
<tr>
<td>9</td>
<td>Test the Web Service.</td>
<td>See Section 3.12, &quot;Testing the Web Service.&quot;</td>
</tr>
<tr>
<td>10</td>
<td>Edit the Web Service. (Optional)</td>
<td>To make changes to the Web Service, update the JWS file, undeploy the Web Service as described in Section 3.9, &quot;Deploying and Undeploying WebLogic Web Services,&quot; then repeat the steps starting from running the <code>jwsc</code> Ant task (Step 6).</td>
</tr>
</tbody>
</table>

See Chapter 6, "Invoking Web Services" for information on writing client applications that invoke a Web Service.
The procedure is just a recommendation; if you have set up your own development environment, you can use this procedure as a guide for updating your existing environment to develop WebLogic Web Services.

It is assumed in this procedure that you already have an existing WSDL file.

---

**Note:** This procedure does not use the WebLogic Web Services split development directory environment. If you are using this development environment, and would like to integrate Web Services development into it, see Section 3.13, "Integrating Web Services Into the WebLogic Split Development Directory Environment" for details.

---

### Table 3–2 Steps to Develop Web Services Starting From Java

</tr>
<tr>
<td>5</td>
<td>Run the <code>wsdlc</code> Ant task against the WSDL file.</td>
<td>The <code>wsdlc</code> Ant task generates the JWS service endpoint interface (SEI), the stubbed-out JWS class file, JavaBeans that represent the XML Schema data types, and so on, into output directories. See Section 3.7, &quot;Running the <code>wsdlc</code> WebLogic Web Services Ant Task.&quot;</td>
</tr>
<tr>
<td>6</td>
<td>Update the stubbed-out JWS file generated by the <code>wsdlc</code> Ant task.</td>
<td>The <code>wsdlc</code> Ant task generates a stubbed-out JWS file. You need to add your business code to the Web Service so it behaves as you want. See Section 3.8, &quot;Updating the Stubbed-out JWS Implementation Class File Generated By <code>wsdlc</code>.&quot;</td>
</tr>
<tr>
<td>7</td>
<td>Run the <code>jwsc</code> Ant task against the JWS file.</td>
<td>Specify the artifacts generated by the <code>wsdlc</code> Ant task as well as your updated JWS implementation file, to generate an Enterprise Application that implements the Web Service. See Section 3.6, &quot;Running the <code>jwsc</code> WebLogic Web Services Ant Task.&quot;</td>
</tr>
<tr>
<td>8</td>
<td>Deploy the Web Service to WebLogic Server.</td>
<td>See Section 3.9, &quot;Deploying and Undeploying WebLogic Web Services.&quot;</td>
</tr>
</tbody>
</table>
3.5 Creating the Basic Ant build.xml File

Ant uses build files written in XML (default name build.xml) that contain a <project> root element and one or more targets that specify different stages in the Web Services development process. Each target contains one or more tasks, or pieces of code that can be executed. This section describes how to create a basic Ant build file; later sections describe how to add targets to the build file that specify how to execute various stages of the Web Services development process, such as running the jwsc Ant task to process a JWS file and deploying the Web Service to WebLogic Server.

The following skeleton build.xml file specifies a default all target that calls all other targets that will be added in later sections:

```xml
<project default='all'>
    <target name='all' depends='clean,build-service,deploy' />
    <target name='clean'>
        <delete dir='output' />
    </target>
    <target name='build-service'>
        <!--add jwsc and related tasks here -->
    </target>
    <target name='deploy'>
        <!--add wldeploy task here -->
    </target>
</project>
```

See Chapter 6, "Invoking Web Services" for information on writing client applications that invoke a Web Service.
3.6 Running the jwsc WebLogic Web Services Ant Task

The jwsc Ant task takes as input a JWS file that contains JWS annotations and generates all the artifacts you need to create a WebLogic Web Service. The JWS file can be either one you coded yourself from scratch or one generated by the wsdlc Ant task. The jwsc-generated artifacts include:

- JSR-109 Web Service class file.
- All required deployment descriptors, including:
  - JAX-RPC mapping files.
  - Java class-implemented Web Services: web.xml and weblogic.xml.
  - Ear deployment descriptor files: application.xml and weblogic-application.xml.
- The XML Schema representation of any Java user-defined types used as parameters or return values to the Web Service operations.
- The WSDL file that publicly describes the Web Service.

If you are running the jwsc Ant task against a JWS file generated by the wsdlc Ant task, the jwsc task does not generate these artifacts, because the wsdlc Ant task already generated them for you and packaged them into a JAR file. In this case, you use an attribute of the jwsc Ant task to specify this wsdlc-generated JAR file.

After generating all the required artifacts, the jwsc Ant task compiles the Java files (including your JWS file), packages the compiled classes and generated artifacts into a deployable JAR archive file, and finally creates an exploded Enterprise Application directory that contains the JAR file.

To run the jwsc Ant task, add the following taskdef and build-service target to the build.xml file:

```xml
<taskdef name="jwsc"
  classname="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
  <jwsc
    srcdir="src_directory"
    destdir="ear_directory"
  >
    <jws file="JWS_file"
      compiledWsdl="WSDL_Generated_JAR"
      type="WebService_type"/>
  </jwsc>
</target>
```

where:

- ear_directory refers to an Enterprise Application directory that will contain all the generated artifacts.
- src_directory refers to the top-level directory that contains subdirectories that correspond to the package name of your JWS file.
- JWS_file refers to the full pathname of your JWS file, relative to the value of the src_directory attribute.
Running the jwsc WebLogic Web Services Ant Task

- **WSDL_C_Generated_JAR** refers to the JAR file generated by the *wsdlc* Ant task that contains the JWS SEI and data binding artifacts that correspond to an existing WSDL file.

  **Note:** You specify this attribute only in the “starting from WSDL” use case; this procedure is described in Section 3.4, “Developing WebLogic Web Services Starting From a WSDL File: Main Steps.”

- **WebService_type** specifies the type of Web Service. This value can be set to JAXWS or JAXRPC.

The required `taskdef` element specifies the full class name of the jwsc Ant task.

Only the `srcdir` and `destdir` attributes of the jwsc Ant task are required. This means that, by default, it is assumed that Java files referenced by the JWS file (such as JavaBeans input parameters or user-defined exceptions) are in the same package as the JWS file. If this is not the case, use the `sourcepath` attribute to specify the top-level directory of these other Java files. See “jwsc” in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for more information.

### 3.6.1 Examples of Using jwsc

The following `build.xml` excerpt shows a basic example of running the jwsc Ant task on a JWS file:

```xml
<taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
    <jwsc
        srcdir="src"
        destdir="output/helloWorldEar">
        <jws
            file="examples/webservices/hello_world/HelloWorldImpl.java"
            type="JAXRPC"/>
    </jwsc>
</target>
```

In the example:

- The Enterprise application will be generated, in exploded form, in `output/helloWorldEar`, relative to the current directory.
- The JWS file is called `HelloWorldImpl.java`, and is located in the `src/examples/webservices/hello_world` directory, relative to the current directory. This implies that the JWS file is in the package `examples.webservices.helloWorld`.
- A JAX-RPC Web Service is generated.

The following example is similar to the preceding one, except that it uses the `compiledWsdl` attribute to specify the JAR file that contains *wsdlc*-generated artifacts (for the “starting with WSDL” use case):

```xml
<taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
    <jwsc
        srcdir="src"
        destdir="output/wsdlcEar">
        <jws
            file="examples/webservices/wsdlc/HelloWorldImpl.java"
            type="WSDL"/>
    </jwsc>
</target>
```
file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java"
compiledWsdl="output/compiledWsdl/TemperatureService_wsd1.jar"
type="JAXRPC"/>
</jwsc>
</target>

In the preceding example, the TemperaturePortTypeImpl.java file is the stubbed-out JWS file that you updated to include your business logic. Because the compiledWsdl attribute is specified and points to a JAR file, the jwsc Ant task does not regenerate the artifacts that are included in the JAR.

To actually run this task, type at the command line the following:

```
prompt> ant build-service
```

### 3.6.2 Advanced Uses of jwsc

This section described two very simple examples of using the jwsc Ant task. The task, however, includes additional attributes and child elements that make the tool very powerful and useful. For example, you can use the tool to:

- Process multiple JWS files at once. You can choose to package each resulting Web Service into its own Web application WAR file, or group all of the Web Services into a single WAR file.
- Specify the transports (HTTP/HTTPS/JMS) that client applications can use when invoking the Web Service, possibly overriding any existing @WLXXXTransport annotations.
- Automatically generate the JAX-RPC client stubs of any other Web Service that is invoked within the JWS file.
- Update an existing Enterprise Application or Web application, rather than generate a completely new one.

See "jwsc" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for complete documentation and examples about the jwsc Ant task.

### 3.7 Running the wsdlc WebLogic Web Services Ant Task

The wsdlc Ant task takes as input a WSDL file and generates artifacts that together partially implement a WebLogic Web Service. These artifacts include:

- JWS service endpoint interface (SEI) that implements the Web Service described by the WSDL file.
- JWS implementation file that contains a partial (stubbed-out) implementation of the generated JWS SEI. This file must be customized by the developer.
- Data binding artifacts used by WebLogic Server to convert between the XML and Java representations of the Web Service parameters and return values.
- Optional Javadocs for the generated JWS SEI.

The wsdlc Ant task packages the JWS SEI and data binding artifacts together into a JAR file that you later specify to the jwsc Ant task. You never need to update this JAR file; the only file you update is the JWS implementation class.

To run the wsdlc Ant task, add the following taskdef and generate-from-wsdl targets to the build.xml file:

```
<taskdef name="wsdlc"
Running the wsdlc WebLogic Web Services Ant Task

```xml
<taskdef name="generate-from-wsdl">
  <wsdlc
      srcWsdl="WSDL_file"
      destJwsDir="JWS_interface_directory"
      destImplDir="JWS_implementation_directory"
      packageName="Package_name"
      type="WebService_type"/>
</target>
```

where:

- **WSDL_file** refers to the name of the WSDL file from which you want to generate a partial implementation, including its absolute or relative pathname.

- **JWS_interface_directory** refers to the directory into which the JAR file that contains the JWS SEI and data binding artifacts should be generated. The name of the generated JAR file is `WSDLFile_wsdl.jar`, where `WSDLFile` refers to the root name of the WSDL file. For example, if the name of the WSDL file you specify to the file attribute is `MyService.wsdl`, then the generated JAR file is `MyService_wsdl.jar`.

- **JWS_implementation_directory** refers to the top directory into which the stubbed-out JWS implementation file is generated. The file is generated into a subdirectory hierarchy corresponding to its package name. The name of the generated JWS file is `PortTypeImpl.java`, where `PortType` refers to the name attribute of the `<portType>` element in the WSDL file for which you are generating a Web Service. For example, if the port type name is `MyServicePortType`, then the JWS implementation file is called `MyServicePortTypeImpl.java`.

- **Package_name** refers to the package into which the generated JWS SEI and implementation files should be generated. If you do not specify this attribute, the `wsdlc` Ant task generates a package name based on the `targetNamespace` of the WSDL.

- **WebService_type** specifies the type of Web Service. This value can be set to JAXWS or JAXRPC.

The required `taskdef` element specifies the full class name of the `wsdlc` Ant task.

Only the `srcWsdl` and `destJwsDir` attributes of the `wsdlc` Ant task are required. Typically, however, you generate the stubbed-out JWS file to make your programming easier. Oracle recommends you explicitly specify the package name in case the `targetNamespace` of the WSDL file is not suitable to be converted into a readable package name.

The following `build.xml` excerpt shows an example of running the `wsdlc` Ant task against a WSDL file:

```xml
<taskdef name="wsdlc"
    classname="weblogic.wsee.tools.anttasks.WsdlcTask"/>
<target name="generate-from-wsdl">
  <wsdlc
      srcWsdl="wsdl_files/TemperatureService.wsdl"
      destJwsDir="output/compiledWsdl"
      destImplDir="impl_output"
      packageName="examples.webservices.wsdlc"
      type="JAXRPC"/>
</target>
```
In the example:

- The existing WSDL file is called TemperatureService.wsdl and is located in the wsdl_files subdirectory of the directory that contains the build.xml file.
- The JAR file that will contain the JWS SEI and data binding artifacts is generated to the output/compiledWsdl directory; the name of the JAR file is TemperatureService_wsdl.jar.
- The package name of the generated JWS files is examples.webservices.wsld.
- The stubbed-out JWS file is generated into the impl_output/examples/webservices/wsdlc directory relative to the current directory.
- Assuming that the port type name in the WSDL file is TemperaturePortType, then the name of the JWS implementation file is TemperaturePortTypeImpl.java.
- A JAX-RPC Web Service is generated.

To actually run this task, type the following at the command line:

```
prompt> ant generate-from-wsdl
```

### 3.8 Updating the Stubbed-out JWS Implementation Class File Generated By wsdlc

The wsdlc Ant task generates the stubbed-out JWS implementation file into the directory specified by its destImplDir attribute; the name of the file is PortTypeImpl.java, where PortType is the name of the portType in the original WSDL. The class file includes everything you need to compile it into a Web Service, except for your own business logic.

The JWS class implements the JWS Web Service endpoint interface that corresponds to the WSDL file; the JWS SEI is also generated by wsdlc and is located in the JAR file that contains other artifacts, such as the Java representations of XML Schema data types in the WSDL and so on. The public methods of the JWS class correspond to the operations in the WSDL file.

The wsdlc Ant task automatically includes the @WebService and @WLHttpTransport annotations in the JWS implementation class; the values of the attributes correspond to the equivalent values in the WSDL. For example, the serviceName attribute of @WebService is the same as the name attribute of the <service> element in the WSDL file; the contextPath and serviceUri attributes of @WLHttpTransport together make up the endpoint address specified by the location attribute of the <address> element in the WSDL.

When you update the JWS file, you add Java code to the methods so that the corresponding Web Service operations operate as required. Typically, the generated JWS file contains comments where you should add code, such as:

```
//replace with your impl here
```

In addition, you can add additional JWS annotations to the file, with the following restrictions:

- You can include the following annotations from the standard (JSR-181) `javax.jws` package in the JWS implementation file: @WebService, @HandlerChain,
Deploying and Undeploying WebLogic Web Services

3.9 Deploying and Undeploying WebLogic Web Services

Because Web Services are packaged as Enterprise Applications, deploying a Web Service simply means deploying the corresponding EAR file or exploded directory.

There are a variety of ways to deploy WebLogic applications, from using the Administration Console to using the weblogic.Deployer Java utility. There are also various issues you must consider when deploying an application to a production environment as opposed to a development environment. For a complete discussion about deployment, see Oracle Fusion Middleware Deploying Applications to Oracle WebLogic Server.

This guide, because of its development nature, discusses just two ways of deploying Web Services:
3.9.1 Using the wldeploy Ant Task to Deploy Web Services

The easiest way to deploy a Web Service as part of the iterative development process is to add a target that executes the `wldeploy` WebLogic Ant task to the same `build.xml` file that contains the `jwsc` Ant task. You can add tasks to both deploy and undeploy the Web Service so that as you add more Java code and regenerate the service, you can redeploy and test it iteratively.

To use the `wldeploy` Ant task, add the following target to your `build.xml` file:

```xml
<target name="deploy">
  <wldeploy action="deploy"
    name="DeploymentName"
    source="Source" user="AdminUser"
    password="AdminPassword"
    adminurl="AdminServerURL"
    targets="ServerName"/>
</target>
```

where:

- `DeploymentName` refers to the deployment name of the Enterprise Application, or the name that appears in the Administration Console under the list of deployments.
- `Source` refers to the name of the Enterprise Application EAR file or exploded directory that is being deployed. By default, the `jwsc` Ant task generates an exploded Enterprise Application directory.
- `AdminUser` refers to administrative username.
- `AdminPassword` refers to the administrative password.
- `AdminServerURL` refers to the URL of the Administration Server, typically `t3://localhost:7001`.
- `ServerName` refers to the name of the WebLogic Server instance to which you are deploying the Web Service.

For example, the following `wldeploy` task specifies that the Enterprise Application exploded directory, located in the `output/ComplexServiceEar` directory relative to the current directory, be deployed to the `myServer` WebLogic Server instance. Its deployed name is `ComplexServiceEar`.

```xml
<target name="deploy">
  <wldeploy action="deploy"
    name="ComplexServiceEar"
    source="output/ComplexServiceEar" user="weblogic"
    password="weblogic" verbose="true"
    adminurl="t3://localhost:7001"
    targets="myserver"/>
</target>
```

To actually deploy the Web Service, execute the `deploy` target at the command-line:

```bash
prompt> ant deploy
```

You can also add a target to easily undeploy the Web Service so that you can make changes to its source code, then redeploy it:
When undeploying a Web Service, you do not specify the `source` attribute, but rather undeploy it by its name.

### 3.9.2 Using the Administration Console to Deploy Web Services

To use the Administration Console to deploy the Web Service, first invoke it in your browser using the following URL:

http://host:port/console

where:
- `host` refers to the computer on which WebLogic Server is running.
- `port` refers to the port number on which WebLogic Server is listening (default value is 7001).

Then use the deployment assistants to help you deploy the Enterprise application. For more information on the Administration Console, see the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

### 3.10 Browsing to the WSDL of the Web Service

You can display the WSDL of the Web Service in your browser to ensure that it has deployed correctly.

The following URL shows how to display the Web Service WSDL in your browser:

http://host:port/contextPath/serviceUri?WSDL

where:
- `host` refers to the computer on which WebLogic Server is running (for example, localhost).
- `port` refers to the port number on which WebLogic Server is listening (default value is 7001).
- `contextPath` refers to the context root of the Web Service. There are many places to set the context root (the `contextPath` attribute of the `@WLHttpTransport` annotation, the `<WLHttpTransport>,<module>, or <jws>` element of jwsc) and certain methods take precedence over others. See "Defining the Context Path of a WebLogic Web Service" in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for a complete explanation.
- `serviceUri` refers to the value of the `serviceUri` attribute of the `@WLHttpTransport` JWS annotation of the JWS file that implements your Web Service or `<WLHttpTransport>` child element of the jwsc Ant task; the second takes precedence over the first. If you do not specify any `serviceUri` attribute in either the JWS file or the jwsc Ant task, then the `serviceUri` of the Web Service is the default value: the name of the JWS file without its `.java` extension.
For example, assume you specified the following `@WLHttpTransport` annotation in the JWS file that implements your Web Service

```java
...@WLHttpTransport(contextPath="complex",
       serviceUri="ComplexService",
       portName="ComplexServicePort")
/**
   * This JWS file forms the basis of a WebLogic Web Service.
   *
   */
public class ComplexServiceImpl {
...
```

Further assume that you do not override the `contextPath` or `serviceURI` values by setting equivalent attributes for the `<WLHttpTransport>` element of the `jwsc` Ant task. Then the URL to view the WSDL of the Web Service, assuming the service is running on a host called `ariel` at the default port number (7001), is:

```
http://ariel:7001/complex/ComplexService?WSDL
```

### 3.11 Configuring the Server Address Specified in the Dynamic WSDL

The WSDL of a deployed Web Service (also called *dynamic WSDL*) includes an `<address>` element that assigns an address (URI) to a particular Web Service port. For example, assume that the following WSDL snippet partially describes a deployed WebLogic Web Service called `ComplexService`:

```xml
<definitions name="ComplexServiceDefinitions"
    targetNamespace="http://example.org">
...
<service name="ComplexService">
    <port binding="s0:ComplexServiceSoapBinding" name="ComplexServicePort">
        <s1:address location="http://myhost:7101/complex/ComplexService"/>
    </port>
</service>
</definitions>
```

The preceding example shows that the `ComplexService` Web Service includes a port called `ComplexServicePort`, and this port has an address of `http://myhost:7101/complex/ComplexService`.

WebLogic Server determines the `complex/ComplexService` section of this address by examining the `contextPath` and `serviceURI` attributes of the `@WLXXXTransport` annotations or `jwsc` elements, as described in *Section 3.10, "Browsing to the WSDL of the Web Service."* However, the method WebLogic Server uses to determine the protocol and host section of the address (`http://myhost:7101`, in the example) is more complicated, as described below. For clarity, this section uses the term *server address* to refer to the protocol and host section of the address.

The server address that WebLogic Server publishes in a dynamic WSDL of a deployed Web Service depends on whether the Web Service can be invoked using HTTP/S or JMS, whether you have configured a proxy server, whether the Web Service is deployed to a cluster, or whether the Web Service is actually a callback service.

The following sections reflect these different configuration options, and provide links to procedural information about changing the configuration to suit your needs.
Configuring the Server Address Specified in the Dynamic WSDL

- Section 3.11.1, "Web Service is not a callback service and can be invoked using HTTP/S"
- Section 3.11.2, "Web Service is not a callback service and can be invoked using JMS Transport"
- Section 3.11.3, "Web Service is a callback service"
- Section 3.11.4, "Web Service is invoked using a proxy server"

It is assumed in the sections that you use the WebLogic Server Administration Console to configure cluster and standalone servers.

### 3.11.1 Web Service is not a callback service and can be invoked using HTTP/S

1. If the Web Service is deployed to a cluster, and the cluster **Frontend Host**, **Frontend HTTP Port**, and **Frontend HTTPS Port** are set, then WebLogic Server uses these values in the server address of the dynamic WSDL.

   See "Configure HTTP Settings for a Cluster" in the *Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help*.

2. If the preceding cluster values are not set, but the **Frontend Host**, **Frontend HTTP Port**, and **Frontend HTTPS Port** values are set for the individual server to which the Web Service is deployed, then WebLogic Server uses these values in the server address.

   See "Configure HTTP Protocol" in the *Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help*.

3. If these values are not set for the cluster or individual server, then WebLogic Server uses the server address of the WSDL request in the dynamic WSDL.

### 3.11.2 Web Service is not a callback service and can be invoked using JMS Transport

1. If the Web Service is deployed to a cluster and the **Cluster Address** is set, then WebLogic Server uses this value in the server address of the dynamic WSDL.

   See "Configure Clusters" in the *Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help*.

2. If the cluster address is not set, or the Web Service is deployed to a standalone server, and the **Listen Address** of the server to which the Web Service is deployed is set, then WebLogic Server uses this value in the server address.

   See "Configure Listen Addresses" in the *Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help*.

### 3.11.3 Web Service is a callback service

1. If the callback service is deployed to a cluster, and the cluster **Frontend Host**, **Frontend HTTP Port**, and **Frontend HTTPS Port** are set, then WebLogic Server uses these values in the server address of the dynamic WSDL.

   See "Configure HTTP Settings for a Cluster" in the *Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help*.

2. If the callback service is deployed to either a cluster or a standalone server, and the preceding cluster values are not set, but the **Frontend Host**, **Frontend HTTP Port**, and **Frontend HTTPS Port** values are set for the individual server to which the callback service is deployed, then WebLogic Server uses these values in the server address.
See "Configure HTTP Protocol" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

3. If the callback service is deployed to a cluster, but none of the preceding values are set, but the Cluster Address is set, then WebLogic Server uses this value in the server address.

See "Configure Clusters" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

4. If none of the preceding values are set, but the Listen Address of the server to which the callback service is deployed is set, then WebLogic Server uses this value in the server address.

See "Configure Listen Addresses" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

3.11.4 Web Service is invoked using a proxy server

Although not required, Oracle recommends that you explicitly set the Frontend Host, FrontEnd HTTP Port, and Frontend HTTPS Port of either the cluster or individual server to which the Web Service is deployed to point to the proxy server.

See "Configure HTTP Settings for a Cluster" or "Configure HTTP Protocol" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

3.12 Testing the Web Service

After you have deployed a WebLogic Web Service, you can use the Web Services Test Client, included in the WebLogic Administration Console, to test your service without writing code. You can quickly and easily test any Web Service, including those with complex types and those using advanced features of WebLogic Server such as conversations. The test client automatically maintains a full log of requests allowing you to return to the previous call to view the results.

To test a deployed Web Service using the Administration Console, follow these steps:

1. Invoke the Administration Console in your browser using the following URL:

   http://host:port/console

   where:
   - *host* refers to the computer on which WebLogic Server is running.
   - *port* refers to the port number on which WebLogic Server is listening (default value is 7001).

2. Follow the procedure described in "Test a Web Service" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

3.13 Integrating Web Services Into the WebLogic Split Development Directory Environment

This section describes how to integrate Web Services development into the WebLogic split development directory environment. It is assumed that you understand this WebLogic feature and have set up this type of environment for developing standard Java Platform, Enterprise Edition (Java EE) Version 5 applications and modules, such as EJBs and Web applications, and you want to update the single build.xml file to include Web Services development.
For detailed information about the WebLogic split development directory environment, see "Creating a Split Development Directory for an Application" in Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server and the splitdir/helloWorldEar example installed with WebLogic Server, located in the WL_HOME/samples/server/examples/src/examples directory, where WL_HOME is the top-level directory of your WebLogic Server installation.

1. In the main project directory, create a directory that will contain the JWS file that implements your Web Service.

   For example, if your main project directory is called /src/helloWorldEar, then create a directory called /src/helloWorldEar/helloWebService:

   prompt> mkdir /src/helloWorldEar/helloWebService

2. Create a directory hierarchy under the helloWebService directory that corresponds to the package name of your JWS file.

   For example, if your JWS file is in the package examples.splitdir.hello package, then create a directory hierarchy examples/splitdir/hello:

   prompt> cd /src/helloWorldEar/helloWebService
   prompt> mkdir examples/splitdir/hello

3. Put your JWS file in the just-created Web Service subdirectory of your main project directory (/src/helloWorldEar/helloWebService/examples/splitdir/hello in this example.)

4. In the build.xml file that builds the Enterprise application, create a new target to build the Web Service, adding a call to the jwsc WebLogic Web Service Ant task, as described in Section 3.6, "Running the jwsc WebLogic Web Services Ant Task."

   The jwsc srcdir attribute should point to the top-level directory that contains the JWS file (helloWebService in this example). The jwsc destdir attribute should point to the same destination directory you specify for wlcompile, as shown in the following example:

   ```xml
   <target name="build.helloWebService">
     <jwsc
       srcdir="helloWebService"
       destdir="destination_dir"
       keepGenerated="yes">
       <jws file="examples/splitdir/hello/HelloWorldImpl.java"
            type="JAXRPC"/>
     </jwsc>
   </target>
   ```

   In the example, destination_dir refers to the destination directory that the other split development directory environment Ant tasks, such as wlappc and wlcompile, also use.

5. Update the main build target of the build.xml file to call the Web Service-related targets:

   ```xml
   <!-- Builds the entire helloWorldEar application -->
   <target name="build" description="Compiles helloWorldEar application and runs appc" depends="build-helloWebService,compile,appc"/>
   ```
6. If you use the `wlcompile` and `wlappc` Ant tasks to compile and validate the entire Enterprise Application, be sure to exclude the Web Service source directory for both Ant tasks. This is because the `jwsc` Ant task already took care of compiling and packaging the Web Service. For example:

```
<target name="compile">
  <wlcompile srcdir="${src.dir}" destdir="${dest.dir}" excludes="appStartup,helloWebService">
    ...
  </wlcompile>
...
</target>
```

```
<target name="appc">
  <wlappc source="${dest.dir}" deprecation='yes' debug='false' excludes='helloWebService'/>
</target>
```

7. Update the `application.xml` file in the `META-INF` project source directory, adding a `<web>` module and specifying the name of the WAR file generated by the `jwsc` Ant task.

For example, add the following to the `application.xml` file for the `helloWorld` Web Service:

```
<application>
  ...  
  <module>
    <web>
      <web-uri>examples/splitdir/hello/HelloWorldImpl.war</web-uri>
      <context-root>/hello</context-root>
    </web>
  </module>
  ...
</application>
```

**Note:** When you actually build your Enterprise Application, be sure you run the `jwsc` Ant task before you run the `wlappc` Ant task. This is because `wlappc` requires some of the artifacts generated by `jwsc` for it to execute successfully. In the example, this means that you should specify the `build-helloWebService` target before the `appc` target.

Your split development directory environment is now updated to include Web Service development. When you rebuild and deploy the entire Enterprise Application, the Web Service will also be deployed as part of the EAR. You invoke the Web Service in the standard way described in Section 3.10, "Browsing to the WSDL of the Web Service."
This chapter describes how to program the JWS file that implements the WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- Section 4.1, "Overview of JWS Files and JWS Annotations"
- Section 4.2, "Java Requirements for a JWS File"
- Section 4.3, "Programming the JWS File: Typical Steps"
- Section 4.4, "Accessing Run-Time Information About a Web Service"
- Section 4.5, "Should You Implement a Stateless Session EJB?"
- Section 4.6, "Programming the User-Defined Java Data Type"
- Section 4.7, "Throwing Exceptions"
- Section 4.8, "Invoking Another Web Service from the JWS File"
- Section 4.9, "Programming Additional Miscellaneous Features Using JWS Annotations and APIs"
- Section 4.10, "JWS Programming Best Practices"

### 4.1 Overview of JWS Files and JWS Annotations

There are two ways to program a WebLogic Web service from scratch:

1. Annotate a standard EJB or Java class with Web service Java annotations, as defined by JSR-181, the JAX-WS specification, and by the WebLogic Web services programming model.

2. Combine a standard EJB or Java class with the various XML descriptor files and artifacts specified by JSR-109 (such as, deployment descriptors, WSDL files, data mapping descriptors, data binding artifacts for user-defined data types, and so on).

Oracle strongly recommends using option 1 above. Instead of authoring XML metadata descriptors yourself, the WebLogic Ant tasks and run time will generate the required descriptors and artifacts based on the annotations you include in your JWS. Not only is this process much easier, but it keeps the information about your Web service in a central location, the JWS file, rather than scattering it across many Java and XML files.

The Java Web Service (JWS) annotated file is the core of your Web service. It contains the Java code that determines how your Web service behaves. A JWS file is an ordinary Java class file that uses Java metadata annotations to specify the shape and
characteristics of the Web service. The JWS annotations you can use in a JWS file include the standard ones defined by the Web Services Metadata for the Java Platform specification (JSR-181), described at http://www.jcp.org/en/jsr/detail?id=181, plus a set of additional annotations based on the type of Web service you are building—JAX-WS or JAX-RPC. For a complete list of JWS annotations that are supported for JAX-WS and JAX-RPC Web services, see “Web Service Annotation Support” in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server.

When programming the JWS file, you include annotations to program basic Web service features. The annotations are used at different levels, or targets, in your JWS file. Some are used at the class-level to indicate that the annotation applies to the entire JWS file. Others are used at the method-level and yet others at the parameter level.

4.2 Java Requirements for a JWS File

When you program your JWS file, you must follow a set of requirements, as specified by the Web Services Metadata for the Java Platform specification (JSR-181) at http://www.jcp.org/en/jsr/detail?id=181. In particular, the Java class that implements the Web service:

- Must be an outer public class, must not be declared final, and must not be abstract.
- Must have a default public constructor.
- Must not define a finalize() method.
- Must include, at a minimum, a @WebService JWS annotation at the class level to indicate that the JWS file implements a Web service.
- May reference a service endpoint interface by using the @WebService.endpointInterface annotation. In this case, it is assumed that the service endpoint interface exists and you cannot specify any other JWS annotations in the JWS file other than @WebService.endpointInterface, @WebService.serviceName and @WebService.targetNamespace.
- If JWS file does not implement a service endpoint interface, all public methods other than those inherited from java.lang.Object will be exposed as Web service operations. This behavior can be overridden by using the @WebMethod annotation to specify explicitly the public methods that are to be exposed. If a @WebMethod annotation is present, only the methods to which it is applied are exposed.

4.3 Programming the JWS File: Typical Steps

The following procedure describes the typical steps for programming a JWS file that implements a Web service.

**Note:** It is assumed that you have created a JWS file and now want to add JWS annotations to it.

For more information about each of the JWS annotations, see "JWS Annotation Reference" in Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server. See Oracle Fusion Middleware Programming Advanced Features of JAX-RPC Web Services for Oracle WebLogic Server for information on using other JWS annotations to program more advanced features, such as Web service reliable messaging, conversations, SOAP message handlers, and so on.
Table 4–1  Steps to Program the JWS File

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Import the standard JWS annotations that will be used in your JWS file.</td>
<td>The standard JWS annotations are in either the javax.jws or javax.jws.soap package. For example: import javax.jws.WebMethod; import javax.jws.WebService; import javax.jws.soap.SOAPBinding;</td>
</tr>
<tr>
<td>2</td>
<td>Import the WebLogic-specific annotations used in your JWS file.</td>
<td>The WebLogic-specific annotations are in the weblogic.jws package. For example: import weblogic.jws.WLHttpTransport;</td>
</tr>
<tr>
<td>3</td>
<td>Add the standard required @WebService JWS annotation at the class level to specify that the Java class exposes a Web service.</td>
<td>See Section 4.3.2, &quot;Specifying that the JWS File Implements a Web Service (@WebService Annotation).&quot;</td>
</tr>
<tr>
<td>4</td>
<td>Add the standard @SOAPBinding JWS annotation at the class level to specify the mapping between the Web service and the SOAP message protocol. (Optional)</td>
<td>In particular, use this annotation to specify whether the Web service is document-literal, RPC-encoded, and so on. See Section 4.3.3, &quot;Specifying the Mapping of the Web Service to the SOAP Message Protocol (@SOAPBinding Annotation).&quot; Although this JWS annotation is not required, Oracle recommends you explicitly specify it in your JWS file to clarify the type of SOAP bindings a client application uses to invoke the Web service.</td>
</tr>
<tr>
<td>5</td>
<td>Add the WebLogic-specific @WLHttpTransport JWS annotation at the class level to specify the context path and service URI used in the URL that invokes the Web service. (Optional)</td>
<td>See Section 4.3.4, &quot;Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation).&quot; Although this JWS annotation is not required, Oracle recommends you explicitly specify it in your JWS file so that it is clear what URL a client application uses to invoke the Web service.</td>
</tr>
<tr>
<td>6</td>
<td>Add the standard @WebMethod annotation for each method in the JWS file that you want to expose as a public operation. (Optional)</td>
<td>Optionally specify that the operation takes only input parameters but does not return any value by using the standard @OneWay annotation. See Section 4.3.5, &quot;Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and @OneWay Annotations).&quot;</td>
</tr>
<tr>
<td>7</td>
<td>Add @WebParam annotation to customize the name of the input parameters of the exposed operations. (Optional)</td>
<td>See Section 4.3.6, &quot;Customizing the Mapping Between Operation Parameters and WSDL Elements (@WebParam Annotation).&quot;</td>
</tr>
<tr>
<td>8</td>
<td>Add @WebResult annotations to customize the name and behavior of the return value of the exposed operations. (Optional)</td>
<td>See Section 4.3.7, &quot;Customizing the Mapping Between the Operation Return Value and a WSDL Element (@WebResult Annotation).&quot;</td>
</tr>
<tr>
<td>9</td>
<td>Add your business code.</td>
<td>Add your business code to the methods to make the WebService behave as required.</td>
</tr>
</tbody>
</table>

4.3.1 Example of a JWS File

The following sample JWS file shows how to implement a simple Web service.

```java
package examples.webservices.simple;

// Import the standard JWS annotation interfaces
```
import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.soap.SOAPBinding;
// Import the WebLogic-specific JWS annotation interfaces
import weblogic.jws.WLHttpTransport;

// Standard JWS annotation that specifies that the portType name of the Web
// Service is "SimplePortType", the service name is "SimpleService", and the
// targetNamespace used in the generated WSDL is "http://example.org"
@WebService(name="SimplePortType", serviceName="SimpleService",
targetNamespace="http://example.org")
// Standard JWS annotation that specifies the mapping of the service onto the
// SOAP message protocol. In particular, it specifies that the SOAP messages
// are document-literal-wrapped.
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
use=SOAPBinding.Use.LITERAL,
parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
// WebLogic-specific JWS annotation that specifies the context path and
// service URI used to build the URI of the Web Service is
// "simple/SimpleService"
@WLHttpTransport(contextPath="simple", serviceUri="SimpleService",
portName="SimpleServicePort")
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHello
 *
 */
public class SimpleImpl {
    // Standard JWS annotation that specifies that the method should be exposed
    // as a public operation. Because the annotation does not include the
    // member-value 'operationName', the public name of the operation is the
    // same as the method name: sayHello.
    @WebMethod()
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: "+ message + ";"
    }
}

4.3.2 Specifying that the JWS File Implements a Web Service (@WebService Annotation)

Use the standard @WebService annotation to specify, at the class level, that the JWS file implements a Web service, as shown in the following code excerpt:

@WebService(name="SimplePortType", serviceName="SimpleService",
targetNamespace="http://example.org")

In the example, the name of the Web service is SimplePortType, which will later map to the wsdl:portType element in the WSDL file generated by the jwsc Ant task. The service name is SimpleService, which will map to the wsdl:service element in the generated WSDL file. The target namespace used in the generated WSDL is http://example.org.

You can also specify the following additional attributes of the @WebService annotation:

- endpointInterface—Fully qualified name of an existing service endpoint interface file. This annotation allows the separation of interface definition from the implementation. If you specify this attribute, the jwsc Ant task does not generate
the interface for you, but assumes you have created it and it is in your CLASSPATH.

- portname—Name that is used in the wsdl:port.

None of the attributes of the @WebService annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at http://www.jcp.org/en/jar/detail?id=181 for the default values of each attribute.

### 4.3.3 Specifying the Mapping of the Web Service to the SOAP Message Protocol (@SOAPBinding Annotation)

It is assumed that you want your Web service to be available over the SOAP message protocol; for this reason, your JWS file should include the standard @SOAPBinding annotation, at the class level, to specify the SOAP bindings of the Web service (such as, RPC-encoded or document-literal-wrapped), as shown in the following code excerpt:

```java
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
             use=SOAPBinding.Use.LITERAL,
             parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
```

In the example, the Web service uses document-wrapped-style encodings and literal message formats, which are also the default formats if you do not specify the @SOAPBinding annotation.

You can also use the WebLogic-specific @weblogic.jws.soap.SOAPBinding annotation to specify the SOAP binding at the method level; the attributes are the same as the standard @javax.jws.soap.SOAPBinding annotation.

You use the `parameterStyle` attribute (in conjunction with the `style=SOAPBinding.Style.DOCUMENT` attribute) to specify whether the Web service operation parameters represent the entire SOAP message body, or whether the parameters are elements wrapped inside a top-level element with the same name as the operation.

### Table 4–2 Attributes of the @SOAPBinding Annotation

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Possible Values</th>
<th>Default Value</th>
</tr>
</thead>
</table>
| style           | SOAPBinding.Style.RPC
                 | SOAPBinding.Style.DOCUMENT    | SOAPBinding.Style.DOCUMENT |
| use             | SOAPBinding.Use.LITERAL
                 | SOAPBinding.Use.ENCODED       | SOAPBinding.Use.LITERAL    |
| parameterStyle  | SOAPBinding.ParameterStyle.BARE
                 | SOAPBinding.ParameterStyle.WRAPPED | SOAPBinding.ParameterStyle.WRAPPED |

### 4.3.4 Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation)

Use the WebLogic-specific @WLHttpTransport annotation to specify the context path and service URI sections of the URL used to invoke the Web service over the HTTP transport, as well as the name of the port in the generated WSDL, as shown in the following code excerpt:

```java
@WLHttpTransport(contextPath="simple", serviceUri="SimpleService",
                 portName="SimpleServicePort")
```

In the example, the name of the port in the WSDL (in particular, the `name` attribute of the `<port>` element) file generated by the jwsc Ant task is `SimpleServicePort`. The
URL used to invoke the Web service over HTTP includes a context path of simple and a service URI of SimpleService, as shown in the following example:

http://host:port/simple/SimpleService

For reference documentation on this and other WebLogic-specific annotations, see "JWS Annotation Reference" in the WebLogic Web Services Reference.

4.3.5 Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and @OneWay Annotations)

Use the standard @WebMethod annotation to specify that a method of the JWS file should be exposed as a public operation of the Web service, as shown in the following code excerpt:

```java
public class SimpleImpl {
    @WebMethod(operationName="sayHelloOperation")
    public String sayHello(String message) {
        System.out.println("sayHello: " + message);
        return "Here is the message: "+ message + ":");
    }
    ...
}
```

In the example, the sayHello() method of the SimpleImpl JWS file is exposed as a public operation of the Web service. The operationName attribute specifies, however, that the public name of the operation in the WSDL file is sayHelloOperation. If you do not specify the operationName attribute, the public name of the operation is the name of the method itself.

You can also use the action attribute to specify the action of the operation. When using SOAP as a binding, the value of the action attribute determines the value of the SOAPAction header in the SOAP messages.

You can specify that an operation not return a value to the calling application by using the standard @Oneway annotation, as shown in the following example:

```java
public class OneWayImpl {
    @WebMethod()
    @Oneway()
    public void ping() {
        System.out.println("ping operation");
    }
    ...
}
```

If you specify that an operation is one-way, the implementing method is required to return void, cannot use a Holder class as a parameter, and cannot throw any checked exceptions.

None of the attributes of the @WebMethod annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at http://www.jcp.org/en/jsr/detail?id=181 for the default values of each attribute, as well as additional information about the @WebMethod and @OneWay annotations.

If none of the public methods in your JWS file are annotated with the @WebMethod annotation, then by default all public methods are exposed as Web service operations.
4.3.6 Customizing the Mapping Between Operation Parameters and WSDL Elements (@WebParam Annotation)

Use the standard @WebParam annotation to customize the mapping between operation input parameters of the Web service and elements of the generated WSDL file, as well as specify the behavior of the parameter, as shown in the following code excerpt:

```java
public class SimpleImpl {
    @WebMethod()
    @WebResult(name="IntegerOutput",
                targetNamespace="http://example.org/docLiteralBare")
    public int echoInt(
        @WebParam(name="IntegerInput",
                    targetNamespace="http://example.org/docLiteralBare")
        int input)
    {
        System.out.println("echoInt '" + input + "' to you too!");
        return input;
    }
    ...
}
```

In the example, the name of the parameter of the `echoInt` operation in the generated WSDL is `IntegerInput`; if the @WebParam annotation were not present in the JWS file, the name of the parameter in the generated WSDL file would be the same as the name of the method’s parameter: `input`. The targetNamespace attribute specifies that the XML namespace for the parameter is `http://example.org/docLiteralBare`; this attribute is relevant only when using document-style SOAP bindings where the parameter maps to an XML element.

You can also specify the following additional attributes of the @WebParam annotation:

- **mode**—The direction in which the parameter is flowing (WebParam.Mode.IN, WebParam.Mode.OUT, or WebParam.Mode.INOUT). The OUT and INOUT modes may be specified only for parameter types that conform to the JAX-RPC definition of Holder types. OUT and INOUT modes are only supported for RPC-style operations or for parameters that map to headers.

- **header**—Boolean attribute that, when set to true, specifies that the value of the parameter should be retrieved from the SOAP header, rather than the default body.

None of the attributes of the @WebParam annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at [http://www.jcp.org/en/jsr/detail?id=181](http://www.jcp.org/en/jsr/detail?id=181) for the default value of each attribute.

4.3.7 Customizing the Mapping Between the Operation Return Value and a WSDL Element (@WebResult Annotation)

Use the standard @WebResult annotation to customize the mapping between the Web service operation return value and the corresponding element of the generated WSDL file, as shown in the following code excerpt:

```java
public class Simple {
    @WebMethod()
    @WebResult(name="IntegerOutput",
                targetNamespace="http://example.org/docLiteralBare")
    public int echoInt(
        @WebParam(name="IntegerInput",
                    targetNamespace="http://example.org/docLiteralBare")
        int input)
    }
    ...
```
4.4 Accessing Run-Time Information About a Web Service

The following sections describe how to access run-time information about a Web service:

- **Section 4.4.1, "Using JwsContext to Access Run-Time Information"**—Use the Web service context to access and change run-time information about the service in your JWS file.
- **Section 4.4.2, "Using the Stub Interface to Access Run-Time Information"**—Get and set properties on the Stub interface in the client file.

### 4.4.1 Using JwsContext to Access Run-Time Information

When a client application invokes a WebLogic Web service that was implemented with a JWS file, WebLogic Server automatically creates a context that the Web service can use to access, and sometimes change, run-time information about the service. Much of this information is related to conversations, such as whether the current conversation is finished, the current values of the conversational properties, changing conversational properties at run time, and so on. (See “Creating Conversational Web Services” in Oracle Fusion Middleware Programming Advanced Features of JAX-RPC Web Services for Oracle WebLogic Server for information about conversations and how to implement them.) Some of the information accessible via the context is more generic, such as the protocol that was used to invoke the Web service (HTTP/S or JMS), the SOAP headers that were in the SOAP message request, and so on.

You can use annotations and WebLogic Web service APIs in your JWS file to access run-time context information, as described in the following sections.

#### 4.4.1.1 Guidelines for Accessing the Web Service Context

The following example shows a simple JWS file that uses the context to determine the protocol that was used to invoke the Web service. The code in **bold** is discussed in the programming guidelines described following the example.

```java
package examples.webservices.jws_context;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Context;
import weblogic.wsee.jws.JwsContext;
```

In the example, the name of the return value of the `echoInt` operation in the generated WSDL is `IntegerOutput`; if the `@WebResult` annotation were not present in the JWS file, the name of the return value in the generated WSDL file would be the hard-coded name `return`. The `targetNamespace` attribute specifies that the XML namespace for the return value is `http://example.org/docLiteralBare`; this attribute is relevant only when using document-style SOAP bindings where the return value maps to an XML element.

None of the attributes of the `@WebResult` annotation is required. See the *Web Services Metadata for the Java Platform* (JSR 181) at [http://www.jcp.org/en/jsr/detail?id=181](http://www.jcp.org/en/jsr/detail?id=181) for the default value of each attribute.
```java
import weblogic.wsee.jws.Protocol;
@WebService(name="JwsContextPortType", serviceName="JwsContextService",
   targetNamespace="http://example.org")
@WLHttpTransport(contextPath="contexts", serviceUri="JwsContext",
   portName="JwsContextPort")
/**
   * Simple web service to show how to use the @Context annotation.
   */
public class JwsContextImpl {
    @Context
    private JwsContext ctx;
    @WebMethod()
    public String getProtocol() {
        Protocol protocol = ctx.getProtocol();
        System.out.println("protocol: " + protocol);
        return "This is the protocol: " + protocol;
    }
}
```

Use the following guidelines in your JWS file to access the run-time context of the Web service, as shown in the code in bold in the preceding example:

- **Import the `@weblogic.jws.Context` JWS annotation:**
  ```java
  import weblogic.jws.Context;
  ```
- **Import the `weblogic.wsee.jws.JwsContext` API, as well as any other related APIs that you might use (the example also uses the `weblogic.wsee.jws.Protocol` API):**
  ```java
  import weblogic.wsee.jws.JwsContext;
  import weblogic.wsee.jws.Protocol;
  ```
  See the `weblogic.wsee.*` packages in the Oracle Fusion Middleware Oracle WebLogic Server API Reference for more documentation about the context-related APIs.
- **Annotate a private variable, of data type `weblogic.wsee.jws.JwsContext`, with the field-level `@Context` JWS annotation:**
  ```java
  @Context
  private JwsContext ctx;
  WebLogic Server automatically assigns the annotated variable (in this case, `ctx`) with a run-time implementation of `JwsContext` the first time the Web service is invoked, which is how you can later use the variable without explicitly initializing it in your code.
  Use the methods of the `JwsContext` class to access run-time information about the Web service. The following example shows how to get the protocol that was used to invoke the Web service.
  ```java
  Protocol protocol = ctx.getProtocol();
  ```
  See Section 4.4.1.2, "Methods of the JwsContext" for the full list of available methods.

### 4.4.1.2 Methods of the JwsContext

The following table summarizes the methods of the `JwsContext` that you can use in your JWS file to access run-time information about the Web service. See `weblogic.wsee.*` packages in the Oracle Fusion Middleware Oracle WebLogic Server API Reference for detailed reference information about `JwsContext`, and other context-related APIs, as `Protocol` and `ServiceHandle`.
### Methods of JwsContext

<table>
<thead>
<tr>
<th>Method</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isFinished()</td>
<td>boolean</td>
<td>Returns a boolean value specifying whether the current conversation is finished, or if it is still continuing. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>finishConversation()</td>
<td>void</td>
<td>Finishes the current conversation. This method is equivalent to a client application invoking a method that has been annotated with the @Conversation (Conversation.Phase.FINISH) JWS annotation. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxAge(java.util.Date)</td>
<td>void</td>
<td>Sets a new maximum age for the conversation to an absolute Date. If the date parameter is in the past, WebLogic Server immediately finishes the conversation. This method is equivalent to the maxAge attribute of the @Conversational annotation, which specifies the default maximum age of a conversation. Use this method to override this default value at run time. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxAge(String)</td>
<td>void</td>
<td>Sets a new maximum age for the conversation by specifying a String duration, such as 1 day. Valid values for the String parameter are a number and one of the following terms: seconds, minutes, hours, days, years. For example, to specify a maximum age of ten minutes, use the following syntax: ctx.setMaxAge(&quot;10 minutes&quot;) This method is equivalent to the maxAge attribute of the @Conversational annotation, which specifies the default maximum age of a conversation. Use this method to override this default value at run time. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>getMaxAge()</td>
<td>long</td>
<td>Returns the maximum allowed age, in seconds, of a conversation. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
</tbody>
</table>
### Table 4–3 (Cont.) Methods of JwsContext

<table>
<thead>
<tr>
<th>Method</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCurrentAge()</td>
<td>long</td>
<td>Returns the current age, in seconds, of the conversation. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>resetIdleTime()</td>
<td>void</td>
<td>Resets the timer which measures the number of seconds since the last activity for the current conversation. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxIdleTime(long)</td>
<td>void</td>
<td>Sets the number of seconds that the conversation can remain idle before WebLogic Server finishes it due to client inactivity. This method is equivalent to the maxIdleTime attribute of the @Conversational annotation, which specifies the default idle time of a conversation. Use this method to override this default value at run time. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxIdleTime(String)</td>
<td>void</td>
<td>Sets the number of seconds, specified as a String, that the conversation can remain idle before WebLogic Server finishes it due to client inactivity. Valid values for the String parameter are a number and one of the following terms: seconds, minutes, hours, days, years. For example, to specify a maximum idle time of ten minutes, use the following syntax: ctx.setMaxIdleTime(&quot;10 minutes&quot;) This method is equivalent to the maxIdleTime attribute of the @Conversational annotation, which specifies the default idle time of a conversation. Use this method to override this default value at run time. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>getMaxIdleTime()</td>
<td>long</td>
<td>Returns the number of seconds that the conversation is allowed to remain idle before WebLogic Server finishes it due to client inactivity. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
</tbody>
</table>
4.4.2 Using the Stub Interface to Access Run-Time Information

The `javax.xml.rpc.Stub` interface enables you to dynamically configure the Stub instance in your Web service client file. For more information, see
http://download.oracle.com/javaee/5/api/javax/xml/rpc/Stub.html. For example, you can set the target service endpoint dynamically for the `portStub` instance, as follows:

```java
ComplexService service = new ComplexService_Impl (args[0] + "?WSDL");
ComplexPortType port = service.getComplexServicePort();
((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY,
"http://localhost:8010/MyContext/MyService");
```

For more information about developing Web service clients, see Chapter 6, "Invoking Web Services."

The following table summarizes the methods of the `Stub` interface that you can use in your JWS file to access run-time information about the Web service.

<table>
<thead>
<tr>
<th>Method</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCurrentIdleTime()</td>
<td>long</td>
<td>Gets the number of seconds since the last client request, or since the conversation's maximum idle time was reset. Use this method only in conversational Web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>getCallerPrincipal()</td>
<td>java.security.Principal</td>
<td>Returns the security principal associated with the operation that was just invoked, assuming that basic authentication was performed.</td>
</tr>
<tr>
<td>isCallerInRole(String)</td>
<td>boolean</td>
<td>Returns true if the authenticated principal is within the specified security role.</td>
</tr>
<tr>
<td>getService()</td>
<td>weblogic.wsee.jws.ServiceHandle</td>
<td>Returns an instance of ServiceHandle, a WebLogic Web service API, which you can query to gather additional information about the Web service, such as the conversation ID (if the Web service is conversational), the URL of the Web service, and so on.</td>
</tr>
<tr>
<td>getLogger(String)</td>
<td>weblogic.wsee.jws.util.Logger</td>
<td>Gets an instance of the Logger class, which you can use to send messages from the Web service to a log file.</td>
</tr>
<tr>
<td>getInputHeaders()</td>
<td>org.w3c.dom.Element[]</td>
<td>Returns an array of the SOAP headers associated with the SOAP request message of the current operation invoke.</td>
</tr>
<tr>
<td>setUnderstoodInputHeaders(boolean)</td>
<td>void</td>
<td>Indicates whether input headers should be understood.</td>
</tr>
<tr>
<td>getUnderstoodInputHeaders()</td>
<td>boolean</td>
<td>Returns the value that was most recently set by a call to setUnderstoodInputHeader.</td>
</tr>
<tr>
<td>setOutputHeaders(Element[])</td>
<td>void</td>
<td>Specifies an array of SOAP headers that should be associated with the outgoing SOAP response message sent back to the client application that initially invoked the current operation.</td>
</tr>
<tr>
<td>getProtocol()</td>
<td>weblogic.wsee.jws.Protocol</td>
<td>Returns the protocol (such as HTTP/S or JMS) used to invoke the current operation.</td>
</tr>
</tbody>
</table>
4.5 Should You Implement a Stateless Session EJB?

The jwsc Ant task always chooses a plain Java object as the underlying implementation of a Web service when processing your JWS file.

Sometimes, however, you might want the underlying implementation of your Web service to be a stateless session EJB so as to take advantage of all that EJBs have to offer, such as instance pooling, transactions, security, container-managed persistence, container-managed relationships, and data caching. If you decide you want an EJB implementation for your Web service, then follow the programming guidelines in the following section.

**Note:** JAX-RPC supports EJB 2.x only; it does not support EJB 3.0.

### 4.5.1 Programming Guidelines When Implementing an EJB in Your JWS File

The general guideline is to always use EJBGen annotations in your JWS file to automatically generate, rather than manually create, the EJB Remote and Home interface classes and deployment descriptor files needed when implementing an EJB. EJBGen annotations work in the same way as JWS annotations: they follow the JDK 5.0 metadata syntax and greatly simplify your programming tasks.

For more information on EJBGen, see "EJBGen Reference" in Oracle Fusion Middleware Programming WebLogic Enterprise JavaBeans for Oracle WebLogic Server.

Follow these guidelines when explicitly implementing a stateless session EJB in your JWS file. See Section 4.5.2, "Example of a JWS File That Implements an EJB" for an example; the relevant sections are shown in bold:

- Import the standard Java Platform, Enterprise Edition (Java EE) Version 5 EJB classes:

---

### Table 4–4 Methods of Stub Interface

<table>
<thead>
<tr>
<th>Method</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>_getProperty()</td>
<td>java.lang.Object</td>
<td>Gets the value of the specified configuration property.</td>
</tr>
<tr>
<td>_getPropertyNames()</td>
<td>java.util.Iterator</td>
<td>Returns an Iterator view of the names of the properties that can be configured on the Stub instance.</td>
</tr>
<tr>
<td>_setProperty()</td>
<td>void</td>
<td>Sets the name and value of a configuration property for the Stub instance.</td>
</tr>
</tbody>
</table>

### Table 4–5 Properties of Stub Interface

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENDPOINT_ADDRESSPROPERTY</td>
<td>java.lang.String</td>
<td>Target service endpoint address.</td>
</tr>
<tr>
<td>PASSWORDPROPERTY</td>
<td>java.lang.String</td>
<td>Password used for authentication.</td>
</tr>
<tr>
<td>SESSION_MAINTAINPROPERTY</td>
<td>java.lang.String</td>
<td>Flag specifying whether to participate in a session with a service endpoint.</td>
</tr>
<tr>
<td>USERNAMEPROPERTY</td>
<td>java.lang.String</td>
<td>User name used for authentication.</td>
</tr>
</tbody>
</table>

Note: JAX-RPC supports EJB 2.x only; it does not support EJB 3.0.
import javax.ejb.SessionBean;
import javax.ejb.SessionContext;

- Import the EJBGen annotations, all of which are in the weblogic.ejbgen package. At a minimum you need to import the @Session annotation; if you want to use additional EJBGen annotations in your JWS file to specify the shape and behavior of the EJB, see the "EJBGen Reference" in Oracle Fusion Middleware Programming WebLogic Enterprise JavaBeans for Oracle WebLogic Server for the name of the annotation you should import.

import weblogic.ejbgen.Session;

- At a minimum, use the @Session annotation at the class level to specify the name of the EJB:

```java
@Session(ejbName="TransactionEJB")
```

@Session is the only required EJBGen annotation when used in a JWS file. You can, if you want, use other EJBGen annotations to specify additional features of the EJB.

- Ensure that the JWS class implements SessionBean:

```java
public class TransactionImpl implements SessionBean {...
```

- You must also include the standard EJB methods ejbCreate(), ejbActivate() and so on, although you typically do not need to add code to these methods unless you want to change the default behavior of the EJB:

```java
public void ejbCreate() {}
public void ejbActivate() {}
public void ejbRemove() {}
public void ejbPassivate() {}
public void setSessionContext(SessionContext sc) {} 
```

If you follow all these guidelines in your JWS file, the jwsc Ant task later compiles the Web service into an EJB and packages it into an EJB JAR file inside of the Enterprise Application.

### 4.5.2 Example of a JWS File That Implements an EJB

The following example shows a simple JWS file that implement a stateless session EJB. The relevant code is shown in **bold**.

```java
package examples.webservices.transactional;
import javax.ejb.SessionBean;
import javax.ejb.SessionContext;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Transactional;
import weblogic.ejbgen.Session;
@Session(ejbName="TransactionEJB")
@WebService(name="TransactionPortType", serviceName="TransactionService",
    targetNamespace="http://example.org")
@WLHttpTransport(contextPath="transactions", serviceUri="TransactionService",
    portName="TransactionPort")
/**
 * This JWS file forms the basis of simple EJB-implemented WebLogic
 * Web Service with a single operation: sayHello. The operation executes
 * as part of a transaction.
 */
```

4-14 Getting Started With JAX-RPC Web Services for Oracle WebLogic Server
public class TransactionImpl implements SessionBean {
    @WebMethod()
    @Transactional(value=true)
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: " + message + ";";
    }
    // Standard EJB methods. Typically there's no need to override the methods.
    public void ejbCreate() {}
    public void ejbActivate() {}
    public void ejbRemove() {}
    public void ejbPassivate() {}
    public void setSessionContext(SessionContext sc) {}
}

4.6 Programming the User-Defined Java Data Type

The methods of the JWS file that are exposed as Web service operations do not necessarily take built-in data types (such as Strings and integers) as parameters and return values, but rather, might use a Java data type that you create yourself. An example of a user-defined data type is TradeResult, which has two fields: a String stock symbol and an integer number of shares traded.

If your JWS file uses user-defined data types as parameters or return values of one or more of its methods, you must create the Java code of the data type yourself, and then import the class into your JWS file and use it appropriately. The jwsc Ant task will later take care of creating all the necessary data binding artifacts, such as the corresponding XML Schema representation of the Java user-defined data type, the JAX-RPC type mapping file, and so on.

Follow these basic requirements when writing the Java class for your user-defined data type:

■ Define a default constructor, which is a constructor that takes no parameters.
■ Define both getXXX() and setXXX() methods for each member variable that you want to publicly expose.
■ Make the data type of each exposed member variable one of the built-in data types, or another user-defined data type that consists of built-in data types.

These requirements are specified by JAX-RPC; for more detailed information and the complete list of requirements, see the JAX-RPC specification at http://java.net/projects/jax-rpc/.

The jwsc Ant task can generate data binding artifacts for most common XML and Java data types. For the list of supported user-defined data types, see Section 5.3, "Supported User-Defined Data Types." See Section 5.2, "Supported Built-In Data Types" for the full list of supported built-in data types.

The following example shows a simple Java user-defined data type called BasicStruct:

package examples.webservices.complex;
/**
   * Defines a simple JavaBean called BasicStruct that has integer, String,
   * and String[] properties
   */
public class BasicStruct {
    // Properties
    private int intValue;
    private String stringValue;
    private String[] stringArray;
    // Getter and setter methods
    public int getIntValue() {
        return intValue;
    }
    public void setIntValue(int intValue) {
        this.intValue = intValue;
    }
    public String getStringValue() {
        return stringValue;
    }
    public void setStringValue(String stringValue) {
        this.stringValue = stringValue;
    }
    public String[] getStringArray() {
        return stringArray;
    }
    public void setStringArray(String[] stringArray) {
        this.stringArray = stringArray;
    }
}

The following snippets from a JWS file show how to import the BasicStruct class and use it as both a parameter and return value for one of its methods; for the full JWS file, see Section 2.2.2, "Sample ComplexImpl.java JWS File":

```java
package examples.webservices.complex;

import examples.webservices.complex.BasicStruct;

public class ComplexImpl {
    @WebMethod(operationName="echoComplexType")
    public BasicStruct echoStruct(BasicStruct struct) {
        return struct;
    }
}
```

4.7 Throwing Exceptions

When you write the error-handling Java code in methods of the JWS file, you can either throw your own user-defined exceptions or throw a javax.xml.rpc.soap.SOAPFaultException exception. If you throw a
SOAPFaultException, WebLogic Server maps it to a SOAP fault and sends it to the client application that invokes the operation.

If your JWS file throws any type of Java exception other than SOAPFaultException, WebLogic Server tries to map it to a SOAP fault as best it can. However, if you want to control what the client application receives and send it the best possible exception information, you should explicitly throw a SOAPFaultException exception or one that extends the exception. See the JAX-RPC specification at http://java.net/projects/jax-rpc/ for detailed information about creating and throwing your own user-defined exceptions.

The following excerpt describes the SOAPFaultException class:

```java
public class SOAPFaultException extends java.lang.RuntimeException {
    public SOAPFaultException (QName faultcode, 
        String faultstring, 
        String faultactor, 
        javax.xml.soap.Detail detail ) {...}
    public QName getFaultCode() {...}
    public String getFaultString() {...}
    public String getFaultActor() {...}
    public javax.xml.soap.Detail getDetail() {...}
}
```

Use the SOAP with Attachments API for Java 1.1 (SAAJ) javax.xml.soap.SOAPFactory.createDetail() method to create the Detail object, which is a container for DetailEntry objects that provide detailed application-specific information about the error.

You can use your own implementation of the SOAPFactory, or use Oracle's, which can be accessed in the JWS file by calling the static method weblogic.wsee.util.WLSOAPFactory.createSOAPFactory() which returns a javax.xml.soap.SOAPFactory object. Then at run time, use the -Djavax.xml.soap.SOAPFactory flag to specify Oracle's SOAPFactory implementation as shown:

```
-Djavax.xml.soap.SOAPFactory=weblogic.xml.saaj.SOAPFactoryImpl
```

The following JWS file shows an example of creating and throwing a SOAPFaultException from within a method that implements an operation of your Web service; the sections in bold highlight the exception code:

```java
package examples.webservices.soap_exceptions;
import javax.xml.namespace.QName;
import javax.xml.soap.Detail;
import javax.xml.soap.SOAPException;
import javax.xml.soap.SOAPFactory;
import javax.xml.rpc.soap.SOAPFaultException;
// Import the @WebService annotation
import javax.jws.WebService;
// Import WLHttpTransport
import weblogic.jws.WLHttpTransport;
@WebService(serviceName="SoapExceptionsService", 
        name="SoapExceptionsPortType", 
        targetNamespace="http://example.org")
@WLHttpTransport(contextPath="exceptions", 
        serviceUri="SoapExceptionsService", 
        portName="SoapExceptionsServicePort")
/**
* This JWS file forms the basis of simple Java-class implemented WebLogic
* Web Service with a single operation: sayHelloWorld
*/
```
public class SoapExceptionsImpl {
    public SoapExceptionsImpl() {
    }
    public void tirarSOAPException() {
        Detail detail = null;
        try {
            SOAPFactory soapFactory = SOAPFactory.newInstance();
            detail = soapFactory.createDetail();
        } catch (SOAPException e) {
            // do something
        }
        QName faultCode = null;
        String faultString = "the fault string";
        String faultActor = "the fault actor";
        throw new SOAPFaultException(faultCode, faultString, faultActor, detail);
    }
}

The preceding example uses the default implementation of SOAPFactory.

Note: If you create and throw your own exception (rather than use SOAPFaultException) and two or more of the properties of your exception class are of the same data type, then you must also create setter methods for these properties, even though the JAX-RPC specification does not require it. This is because when a WebLogic Web service receives the exception in a SOAP message and converts the XML into the Java exception class, there is no way of knowing which XML element maps to which class property without the corresponding setter methods.

4.8 Invoking Another Web Service from the JWS File

From within your JWS file you can invoke another Web service, either one deployed on WebLogic Server or one deployed on some other application server, such as .NET. The steps to do this are similar to those described in Section 2.4, "Invoking a Web Service from a Java SE Client," except that rather than running the clientgen Ant task to generate the client stubs, you include a <clientgen> child element of the jwsc Ant task that builds the invoking Web service to generate the client stubs instead. You then use the standard JAX-RPC APIs in your JWS file.

See Section 6.3, "Invoking a Web Service from Another Web Service" for detailed instructions.

4.9 Programming Additional Miscellaneous Features Using JWS Annotations and APIs

The following sections describe additional miscellaneous features you can program by specifying particular JWS annotations in your JWS file or using WebLogic Web services APIs:

- Section 4.9.1, "Sending Binary Data Using MTOM/XOP"
- Section 4.9.2, "Streaming SOAP Attachments"
- Section 4.9.3, "Using SOAP 1.2"
4.9.1 Sending Binary Data Using MTOM/XOP

SOAP Message Transmission Optimization Mechanism/XML-binary Optimized Packaging (MTOM/XOP) describes a method for optimizing the transmission of XML data of type `xs:base64Binary` in SOAP messages. When the transport protocol is HTTP, MIME attachments are used to carry that data while at the same time allowing both the sender and the receiver direct access to the XML data in the SOAP message without having to be aware that any MIME artifacts were used to marshal the `xs:base64Binary` data. The binary data optimization process involves encoding the binary data, removing it from the SOAP envelope, compressing it and attaching it to the MIME package, and adding references to that package in the SOAP envelope.

The MTOM specification does not require that, when MTOM is enabled, the Web service run time use XOP binary optimization when transmitting `base64binary` data. Rather, the specification allows the run time to choose to do so. This is because in certain cases the run time may decide that it is more efficient to send `base64binary` data directly in the SOAP Message; an example of such a case is when transporting small amounts of data in which the overhead of conversion and transport consumes more resources than just inlining the data as is. The WebLogic Web services implementation for MTOM for JAX-RPC service, however, always uses MTOM/XOP when MTOM is enabled.

Support for MTOM/XOP in WebLogic JAX-RPC Web services is implemented using the pre-packaged WS-Policy file `Mtom.xml`. WS-Policy files follow the `WS-Policy` specification, described at [http://www.w3.org/TR/ws-policy](http://www.w3.org/TR/ws-policy); this specification provides a general purpose model and XML syntax to describe and communicate the policies of a Web service, in this case the use of MTOM/XOP to send binary data. The installation of the pre-packaged `Mtom.xml` WS-Policy file in the `types` section of the Web service WSDL is as follows (provided for your information only; you cannot change this file):

```xml
<wsp:Policy wsu:Id="myService_policy">
    <wsp:ExactlyOne>
        <wsp:All>
            <wsoma:OptimizedMimeSerialization
        </wsp:All>
    </wsp:ExactlyOne>
</wsp:Policy>
```

When you deploy the compiled JWS file to WebLogic Server, the dynamic WSDL will automatically contain the following snippet that references the MTOM WS-Policy file; the snippet indicates that the Web service uses MTOM/XOP:

```xml
<wsdl:binding name="BasicHttpBinding_IMtomTest"
    type="i0:IMtomTest">
    <wsp:PolicyReference URI="#myService_policy" />
    <soap:binding transport="http://schemas.xmlsoap.org/soap/http" />
</wsdl:binding>
```

You can associate the `Mtom.xml` WS-Policy file with a Web service at development-time by specifying the `@Policy` metadata annotation in your JWS file. Be sure you also specify the `attachToWsdl=true` attribute to ensure that the dynamic WSDL includes the required reference to the `Mtom.xml` file; see the example below.
You can associate the Mtom.xml WS-Policy file with a Web service at deployment time by modifying the WSDL to add the Policy to the types section just before deployment.

In addition, you can attach the file at run time using by the Administration Console; for details, see "Associate a WS-Policy file with a Web Service" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help. This section describes how to use the JWS annotation.

**Note:** In this release of WebLogic Server, the only supported Java data type when using MTOM/XOP is byte[]; other binary data types, such as image, are not supported.

In addition, this release of WebLogic Server does not support using MTOM with deprecated 9.x security policies.

To send binary data using MTOM/XOP, follow these steps:

1. **Use the WebLogic-specific @weblogic.jws.Policy annotation** in your JWS file to specify that the pre-packaged Mtom.xml file should be applied to your Web service, as shown in the following simple JWS file (relevant code shown in bold):

   ```java
   package examples.webservices.mtom;
   import javax.jws.WebMethod;
   import javax.jws.WebService;
   import weblogic.jws.WLHttpTransport;
   import weblogic.jws.Policy;
   @WebService(name="MtomPortType",
               serviceName="MtomService",
               targetNamespace="http://example.org")
   @WLHttpTransport(contextPath="mtom",
                    serviceUri="MtomService",
                    portName="MtomServicePort")
   @Policy(uri="policy:Mtom.xml", attachToWsdl=true)
   public class MtomImpl {
      @WebMethod
      public String echoBinaryAsString(byte[] bytes) {
         return new String(bytes);
      }
   }
   ``

2. **Use the Java byte[] data type** in your Web service operations as either a return value or input parameter whenever you want the resulting SOAP message to use MTOM/XOP to send or receive the binary data. See the implementation of the echoBinaryAsString operation above for an example; this operation simply takes as input an array of byte and returns it as a String.

3. The WebLogic Web services run time has built in MTOM/XOP support which is enabled if the WSDL for which the clientgen Ant task generates client-side artifacts specifies MTOM/XOP support. In your client application itself, simply invoke the operations as usual, using byte[] as the relevant data type.

See the SOAP Message Transmission Optimization Mechanism specification at [http://www.w3.org/TR/2005/REC-soap12-mtom-20050125](http://www.w3.org/TR/2005/REC-soap12-mtom-20050125) for additional information about the MTOM/XOP feature itself as well as the version of the specification supported by WebLogic JAX-RPC Web services.
4.9.2 Streaming SOAP Attachments

Using the `@weblogic.jws.StreamAttachments` JWS annotation, you can specify that a Web service use a streaming API when reading inbound SOAP messages that include attachments, rather than the default behavior in which the service reads the entire message into memory. This feature increases the performance of Web services whose SOAP messages are particular large.

See "weblogic.jws.StreamAttachments" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for an example of specifying that attachments should be streamed.

4.9.3 Using SOAP 1.2

WebLogic Web services use, by default, Version 1.1 of Simple Object Access Protocol (SOAP) as the message format when transmitting data and invocation calls between the Web service and its client. WebLogic Web services support both SOAP 1.1 and the newer SOAP 1.2, and you are free to use either version.

To specify that the Web service use Version 1.2 of SOAP, use the class-level `@weblogic.jws.Binding` annotation in your JWS file and set its single attribute to the value `Binding.Type.SOAP12`, as shown in the following example (relevant code shown in bold):

```java
package examples.webservices.soap12;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Binding;
@WebService(name="SOAP12PortType",
            serviceName="SOAP12Service",
            targetNamespace="http://example.org")
@WLHttpTransport(contextPath="soap12",
            serviceUri="SOAP12Service",
            portName="SOAP12ServicePort")
@Binding(Binding.Type.SOAP12)
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic Web Service with a single operation: sayHello. The class uses SOAP 1.2 as its binding.
 */
public class SOAP12Impl {
    @WebMethod()
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return 'Here is the message: "+ message + ";
    }
}
```

Other than set this annotation, you do not have to do anything else for the Web service to use SOAP 1.2, including changing client applications that invoke the Web service; the WebLogic Web services run time takes care of all the rest.

4.9.4 Specifying that Operations Run Inside of a Transaction

When a client application invokes a WebLogic Web service operation, the operation invocation takes place outside the context of a transaction, by default. If you want the operation to run inside a transaction, specify the `@weblogic.jws.Transactional` annotation in your JWS file, and set the boolean value attribute to `true`, as shown in the following example (relevant code shown in **bold**):

```java
package examples.webservices.transactional;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Transactional;

@WebService(name="TransactionPojoPortType",
    serviceName="TransactionPojoService",
    targetNamespace="http://example.org")
@WLHttpTransport(contextPath="transactionsPojo",
    serviceUri="TransactionPojoService",
    portName="TransactionPojoPort")
/**
 * This JWS file forms the basis of simple WebLogic
 * Web Service with a single operation: sayHello. The operation executes
 * as part of a transaction.
 *
 */
public class TransactionPojoImpl {
    @WebMethod()
    @Transactional(value=true)
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: " + message + "\";  
    }
}
```

If you want all operations of a Web service to run inside of a transaction, specify the `@Transactional` annotation at the class-level. If you want only a subset of the operations to be transactional, specify the annotation at the method-level. If there is a conflict, the method-level value overrides the class-level.

4.9.5 Getting the HttpServletRequest/Response Object

If your Web service uses HTTP as its transport protocol, you can use the "weblogic.wsee.connection.transport.servlet.HttpTransportUtils" API in the Oracle Fusion Middleware Oracle WebLogic Server API Reference to get the `javax.servlet.http.HttpServletRequest` and `javax.servlet.http.HttpServletResponse` objects from the JAX-RPC `ServletEndpointContext` object, as shown in the following example (relevant code shown in bold and explained after the example):

```java
package examples.webservices.http_transport_utils;
import javax.xml.rpc.server.ServiceLifecycle;
import javax.xml.rpc.server.ServletEndpointContext;
import javax.xml.rpc.ServiceException;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
import javax.jws.WebMethod;
import javax.jws.WebService;
```

```java
package examples.webservices.http_transport_utils;
import javax.xml.rpc.server.ServiceLifecycle;
import javax.xml.rpc.server.ServletEndpointContext;
import javax.xml.rpc.ServiceException;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
import javax.jws.WebMethod;
import javax.jws.WebService;
```
import weblogic.jws.WLHttpTransport;
import weblogic.wsee.connection.transport.servlet.HttpTransportUtils;

@WebService(name="HttpTransportUtilsPortType",
             serviceName="HttpTransportUtilsService",
             targetNamespace="http://example.org")
@WLHttpTransport(contextPath="servlet", serviceUri="HttpTransportUtils",
                  portName="HttpTransportUtilsPort")
public class HttpTransportUtilsImpl implements ServiceLifecycle {
    private ServletEndpointContext wsctx = null;

    public void init(Object context) throws ServiceException {
        System.out.println("ServletEndpointContext inited...");
        wsctx = (ServletEndpointContext)context;
    }

    public void destroy() {
        System.out.println("ServletEndpointContext destroyed...");
        wsctx = null;
    }

    @WebMethod()
    public String getServletRequestAndResponse() {
        HttpServletRequest request =
            HttpTransportUtils.getHttpServletRequest(wsctx.getMessageContext());
        HttpServletResponse response =
            HttpTransportUtils.getHttpServletResponse(wsctx.getMessageContext());
        System.out.println("HttpTransportUtils API used successfully.");
        return "HttpTransportUtils API used successfully";
    }
}

The important parts of the preceding example are as follows:

- Import the required JAX-RPC and Servlet classes:
  ```
  import javax.xml.rpc.server.ServiceLifecycle;
  import javax.xml.rpc.server.ServletEndpointContext;
  import javax.xml.rpc.ServiceException;
  import javax.servlet.http.HttpServletRequest;
  import javax.servlet.http.HttpServletResponse;
  ```

- Import the WebLogic HttpTransportUtils class:
  ```
  import weblogic.wsee.connection.transport.servlet.HttpTransportUtils;
  ```

- Because you will be querying the JAX-RPC message context, your JWS file must explicitly implement ServiceLifecycle:
  ```
  public class HttpTransportUtilsImpl implements ServiceLifecycle {
  ```

- Create a variable of data type ServletEndpointContext:
  ```
  private ServletEndpointContext wsctx = null;
  ```

- Because the JWS file implements ServiceLifecycle, you must also implement the init and destroy lifecycle methods:
  ```
  public void init(Object context) throws ServiceException {
      System.out.println("ServletEndpointContext inited...");
      wsctx = (ServletEndpointContext)context;
  }

  public void destroy() {
      System.out.println("ServletEndpointContext destroyed...");
      wsctx = null;
  }
  ```
Finally, in the method that implements the Web service operation, use the ServletEndpointContext object to get the HttpServletRequest and HttpServletResponse objects:

```java
HttpServletRequest request = HttpTransportUtils.getHttpServletRequest(wsctx.getMessageContext());
HttpServletResponse response = HttpTransportUtils.getHttpServletResponse(wsctx.getMessageContext());
```

### 4.10 JWS Programming Best Practices

The following list provides some best practices when programming the JWS file:

- When you create a document-literal-bare Web service, use the @WebParam JWS annotation to ensure that all input parameters for all operations of a given Web service have a unique name. Because of the nature of document-literal-bare Web services, if you do not explicitly use the @WebParam annotation to specify the name of the input parameters, WebLogic Server creates one for you and run the risk of duplicating the names of the parameters across a Web service.

- In general, document-literal-wrapped Web services are the most interoperable type of Web service.

- Use the @WebResult JWS annotation to explicitly set the name of the returned value of an operation, rather than always relying on the hard-coded name return, which is the default name of the returned value if you do not use the @WebResult annotation in your JWS file.

- Use SOAPFaultExceptions in your JWS file if you want to control the exception information that is passed back to a client application when an error is encountered while invoking a Web service.

- Even though it is not required, Oracle recommends you always specify the portName attribute of the WebLogic-specific @WLHttpTransport annotation in your JWS file. If you do not specify this attribute, the jwsc Ant task will generate a port name for you when generating the WSDL file, but this name might not be very user-friendly. A consequence of this is that the getXXX() method you use in your client applications to invoke the Web service will not be very well-named. To ensure that your client applications use the most user-friendly methods possible when invoking the Web service, specify a relevant name of the Web service port by using the portName attribute.
This chapter describes the data binding and the data types (both built-in and user-defined) that are supported for WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- **Section 5.1, "Overview of Data Binding"**
- **Section 5.2, "Supported Built-In Data Types"**
- **Section 5.3, "Supported User-Defined Data Types"**

### 5.1 Overview of Data Binding

With the emergence of XML as the standard for exchanging data across disparate systems, Web service applications need a way to access documents that are in XML format directly from the Java application. Specifically, the XML content needs to be converted to a format that is readable by the Java application. **Data binding** describes the conversion of data between its XML and Java representations.

As in previous releases, WebLogic Web services support a full set of built-in XML Schema, Java, and SOAP types, as specified by the JAX-RPC specification, described at [http://java.net/projects/jax-rpc/](http://java.net/projects/jax-rpc/), that you can use in your Web service operations without performing any additional programming steps. Built-in data types are those such as `integer`, `string`, and `time`.

Additionally, you can use a variety of user-defined XML and Java data types, including Apache XmlBeans (in package `org.apache.xmlbeans`), as input parameters and return values of your Web service. User-defined data types are those that you create from XML Schema or Java building blocks, such as `<xsd:complexType>` or JavaBeans. The WebLogic Web services Ant tasks, such as `jwsc` and `clientgen`, automatically generate the data binding artifacts needed to convert the user-defined data types between their XML and Java representations. The XML representation is used in the SOAP request and response messages, and the Java representation is used in the JWS that implements the Web service.
Supported Built-In Data Types

5.2 Supported Built-In Data Types

The following sections describe the built-in data types supported by WebLogic Web services and the mapping between their XML and Java representations. As long as the data types of the parameters and return values of the back-end components that implement your Web service are in the set of built-in data types, WebLogic Server automatically converts the data between XML and Java.

If, however, you use user-defined data types, then you must create the data binding artifacts that convert the data between XML and Java. WebLogic Server includes the jwsc and wsdlc Ant tasks that can automatically generate the data binding artifacts for most user-defined data types. See Section 5.3, "Supported User-Defined Data Types" for a list of supported XML and Java data types.

5.2.1 XML-to-Java Mapping for Built-in Data Types

The following table lists the supported XML Schema data types (target namespace http://www.w3.org/2001/XMLSchema) and their corresponding Java data types.

For a list of the supported user-defined XML data types, see Section 5.2.2, "Java-to-XML Mapping for Built-In Data Types."

Table 5–1 Mapping XML Schema Built-in Data Types to Java Data Types

<table>
<thead>
<tr>
<th>XML Schema Data Type</th>
<th>Equivalent Java Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>byte</td>
<td>byte</td>
</tr>
<tr>

<td>java.util.Calendar</td>
</tr>
<tr>
<td>base64Binary</td>
<td>byte[]</td>
</tr>
</tbody>
</table>

Note: As of WebLogic Server 9.1, using XMLBeans 1.x data types (in other words, extensions of com.bea.xml.XmlObject) as parameters or return types of a WebLogic Web service is deprecated. New applications should use XMLBeans 2.x data types.

If a Web service uses XMLBeans that are compiled with the -noupa option, then -Dweblogic.wsee.bind.setCompileNoUpaRule=true flag is required to be set in the WebLogic server startup script to ensure the Web service deploys successfully. Otherwise, deployment will fail with the following error: cos-nonambig: Content model violates the unique particle attribution rule.

<td>base64Binary</td>
</tr>
<tr>
<td>javax.xml.transform.Source</td>
<td>base64Binary</td>
</tr>
<tr>
<td>java.util.UUID</td>
<td>string</td>
</tr>
</tbody>
</table>
If your XML or Java data type is not listed in these tables, and it is not one of the built-in data types listed in Section 5.2, "Supported Built-In Data Types," then you must create the user-defined data type artifacts manually.

5.3.1 Supported XML User-Defined Data Types

The following table lists the XML Schema data types supported by the jwsc and wsdlc Ant tasks and their equivalent Java data type or mapping mechanism.

For details and examples of the data types, see the JAX-RPC specification at http://java.net/projects/jax-rpc/.

<table>
<thead>
<tr>
<th>XML Schema Data Type</th>
<th>Equivalent Java Data Type or Mapping Mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="">xsd:complexType</a> with elements of both simple and complex types.</td>
<td>JavaBean</td>
</tr>
<tr>
<td><a href="">xsd:complexType</a> with simple content.</td>

<tr>
<td>java.util.HashSet</td>
<td>Literal Array</td>
</tr>
</tbody>
</table>

**Note:** The following user-defined Java data type, used as a parameter or return value of a WebLogic Web service in Version 8.1, is no longer supported: JAX-RPC-style enumeration class.

Additionally, generics are not supported when used as a parameter or return value. For example, the following Java method cannot be exposed as a public operation:

```java
public ArrayList<String> echoGeneric(ArrayList<String> in) {
    return in;
}
```
This chapter describes how to invoke WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- Section 6.1, "Overview of Web Services Invocation"
- Section 6.2, "Invoking a Web Service from a Java SE Client"
- Section 6.3, "Invoking a Web Service from Another Web Service"
- Section 6.4, "Using a Stand-Alone Client JAR File When Invoking Web Services"
- Section 6.5, "Using a Proxy Server When Invoking a Web Service"
- Section 6.6, "Client Considerations When Redeploying a Web Service"
- Section 6.7, "WebLogic Web Services Stub Properties"
- Section 6.8, "Setting the Character Encoding For the Response SOAP Message"

**Note:** The following sections do not include information about invoking message-secured Web services; for that topic, see "Updating a Client Application to Invoke a Message-Secured Web Service" in *Oracle Fusion Middleware Securing WebLogic Web Services for Oracle WebLogic Server*.

### 6.1 Overview of Web Services Invocation

Invoking a Web service refers to the actions that a client application performs to use the Web service. Client applications that invoke Web services can be written using any technology: Java, Microsoft .NET, and so on.

There are two types of client applications:

- **Java SE client**—In its simplest form, a Java SE client is a Java program that has the `Main` public class that you invoke with the `java` command.

- **Java EE component deployed to WebLogic Server**—In this type of client application, the Web service runs inside a Java Platform, Enterprise Edition (Java EE) Version 5 component deployed to WebLogic Server, such as an EJB, servlet, or another Web service. This type of client application, therefore, runs inside a WebLogic Server container.

You can invoke a Web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for *stand-alone* Java applications that are running in an environment
where WebLogic Server libraries are not available, see Section 6.4, "Using a Stand-Alone Client JAR File When Invoking Web Services".

The sections that follow describe how to use Oracle's implementation of the JAX-RPC specification to invoke a Web service from a Java client application. You can use this implementation to invoke Web services running on any application server, both WebLogic and non-WebLogic. In addition, you can create a client that runs as part of a WebLogic Server, or a stand-alone client that runs in an environment where WebLogic Server libraries are not available.

In addition to the command-line tools described in this section, you can use an IDE, such as Oracle JDeveloper, for proxy generation and testing. For more information, see "Using Oracle IDEs to Build Web Services" in Oracle Fusion Middleware Introducing WebLogic Web Services for Oracle WebLogic Server.

---

**Note:** You cannot use a dynamic client to invoke a Web service operation that implements user-defined data types as parameters or return values. A dynamic client uses the JAX-RPC Call interface. Standard (static) clients use the Service and Stub JAX-RPC interfaces, which correctly invoke Web services that implement user-defined data types.

---

### 6.1.1 Invoking Web Services Using JAX-RPC

The Java API for XML based RPC (JAX-RPC) is a specification that defines the APIs used to invoke a Web service. WebLogic Server implements the JAX-RPC specification.

The following table briefly describes the core JAX-RPC interfaces and classes.

<table>
<thead>
<tr>
<th>javax.xml.rpc Interface or Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>Main client interface.</td>
</tr>
<tr>
<td>ServiceFactory</td>
<td>Factory class for creating Service instances.</td>
</tr>
<tr>
<td>Stub</td>
<td>Base class of the client proxy used to invoke the operations of a Web service.</td>
</tr>
<tr>
<td>Call</td>
<td>Used to dynamically invoke a Web service.</td>
</tr>
<tr>
<td>JAXRPCException</td>
<td>Exception thrown if an error occurs while invoking a Web service.</td>
</tr>
</tbody>
</table>

### 6.1.2 Examples of Clients That Invoke Web Services

WebLogic Server includes examples of creating and invoking WebLogic Web services in the WL_HOME/samples/server/examples/src/examples/webservices directory, where WL_HOME refers to the main WebLogic Server directory. For detailed instructions on how to build and run the examples, open the WL_HOME/samples/server/docs/index.html Web page in your browser and expand the WebLogic Server Examples->Examples->API->Web Services node.
6.2 Invoking a Web Service from a Java SE Client

**Note:** As described in this section, you can invoke a Web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for stand-alone Java applications that are running in an environment where WebLogic Server libraries are not available, see Section 6.4, "Using a Stand-Alone Client JAR File When Invoking Web Services".

The following table summarizes the main steps to create a Java SE client that invokes a Web service.

**Note:** It is assumed that you use Ant in your development environment to build your client application, compile Java files, and so on, and that you have an existing `build.xml` file that you want to update with Web services client tasks. For general information about using Ant in your development environment, see Section 3.5, "Creating the Basic Ant `build.xml` File." For a full example of a `build.xml` file used in this section, see Section 6.2.5, "Sample Ant Build File for a Java Client."

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set up the environment.</td>
<td>Open a command window and execute the <code>setDomainEnv.cmd</code> (Windows) or <code>setDomainEnv.sh</code> (UNIX) command, located in the <code>bin</code> subdirectory of your domain directory. The default location of WebLogic Server domains is <code>MW_HOME/user_projects/domains/domainName</code>, where <code>MW_HOME</code> is the top-level installation directory of the Oracle products and <code>domainName</code> is the name of your domain.</td>
</tr>
<tr>
<td>2</td>
<td>Update your <code>build.xml</code> file to execute the <code>clientgen</code> Ant task to generate the needed client-side artifacts to invoke a Web service.</td>
<td>See Section 6.2.1, &quot;Using the clientgen Ant Task To Generate Client Artifacts.&quot;</td>
</tr>
<tr>
<td>3</td>
<td>Get information about the Web service, such as the signature of its operations and the name of the ports.</td>
<td>See Section 6.2.2, &quot;Getting Information About a Web Service.&quot;</td>

<td>Write the client application Java code that includes code for invoking the Web service operation.</td>
<td>See Section 6.2.3, &quot;Writing the Java Client Application Code to Invoke a Web Service.&quot;</td>
</tr>
<tr>
<td>5</td>
<td>Create a basic Ant build file, <code>build.xml</code>.</td>
<td>See Section 3.5, &quot;Creating the Basic Ant <code>build.xml</code> File.&quot;</td>
</tr>
<tr>
<td>6</td>
<td>Compile and run your Java client application.</td>
<td>See Section 6.2.4, &quot;Compiling and Running the Client Application.&quot;</td>
</tr>
</tbody>
</table>
6.2.1 Using the clientgen Ant Task To Generate Client Artifacts

The clientgen WebLogic Web services Ant task generates, from an existing WSDL file, the client artifacts that client applications use to invoke both WebLogic and non-WebLogic Web services. These artifacts include:

- The Java class for the JAX-RPC Stub and Service interface implementations for the particular Web service you want to invoke.
- The Java class for any user-defined XML Schema data types included in the WSDL file.
- The JAX-RPC mapping deployment descriptor file which contains information about the mapping between the Java user-defined data types and their corresponding XML Schema types in the WSDL file.
- A client-side copy of the WSDL file.

For additional information about the clientgen Ant task, such as all the available attributes, see "Ant Task Reference" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server.

Update your build.xml file, adding a call to the clientgen Ant task, as shown in the following example:

```xml
<taskdef name="clientgen"
  classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
<target name="build-client">
  <clientgen
    wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="clientclasses"
    packageName="examples.webservices.simple_client"
    type="JAXRPC"/>
</target>
```

Before you can execute the clientgen WebLogic Web service Ant task, you must specify its full Java classname using the standard taskdef Ant task.

You must include the wsdl and destDir attributes of the clientgen Ant task to specify the WSDL file from which you want to create client-side artifacts and the directory into which these artifacts should be generated. The packageName attribute is optional; if you do not specify it, the clientgen task uses a package name based on the targetNamespace of the WSDL. The type is also optional; if not specified, it defaults to JAXRPC.

In this example, the package name is set to the same package name as the client application, examples.webservices.simple_client. If you set the package name to one that is different from the client application, you would need to import the appropriate class files. For example, if you defined the package name as examples.webservices.complex, you would need to import the following class files in the client application:

```java
import examples.webservices.complex.BasicStruct;
import examples.webservices.complex.ComplexPortType;
import examples.webservices.complex.ComplexService;
```
If the WSDL file specifies that user-defined data types are used as input parameters or return values of Web service operations, `clientgen` automatically generates a JavaBean class that is the Java representation of the XML Schema data type defined in the WSDL. The JavaBean classes are generated into the `destDir` directory.

**Note:** The package of the Java user-defined data type is based on the XML Schema of the data type in the WSDL, which is different from the package name of the JAX-RPC stubs.

For a full sample build.xml file that contains additional targets from those described in this procedure, such as `clean`, see Section 6.2.5, "Sample Ant Build File for a Java Client."

To execute the `clientgen` Ant task, along with the other supporting Ant tasks, specify the `build-client` target at the command line:

```plaintext
prompt> ant build-client
```

See the `clientclasses` directory to view the files and artifacts generated by the `clientgen` Ant task.

### 6.2.2 Getting Information About a Web Service

You need to know the name of the Web service and the signature of its operations before you write your Java client application code to invoke an operation. There are a variety of ways to find this information.

The best way to get this information is to use the `clientgen` Ant task to generate the Web service-specific JAX-RPC stubs and look at the generated *.java files. These files are generated into the directory specified by the `destDir` attribute, with subdirectories corresponding to either the value of the `packageName` attribute, or, if this attribute is not specified, to a package based on the `targetNamespace` of the WSDL.

- The `serviceName.java` source file contains the `getPortName()` methods for getting the Web service port, where `serviceName` refers to the name of the Web service and `PortName` refers to the name of the port. If the Web service was implemented with a JWS file, the name of the Web service is the value of the `serviceName` attribute of the `@WebService` JWS annotation and the name of the port is the value of the `portName` attribute of the `@WLHttpTransport` annotation.

- The `PortType.java` file contains the method signatures that correspond to the public operations of the Web service, where `PortType` refers to the port type of the Web service. If the Web service was implemented with a JWS file, the port type is the value of the `name` attribute of the `@WebService` JWS annotation.

You can also examine the actual WSDL of the Web service; see Section 3.10, "Browsing to the WSDL of the Web Service" for details about the WSDL of a deployed WebLogic Web service. The name of the Web service is contained in the `<service>` element, as shown in the following excerpt of the `TraderService` WSDL:
The operations defined for this Web service are listed under the corresponding `<binding>` element. For example, the following WSDL excerpt shows that the TraderService Web service has two operations, buy and sell (for clarity, only relevant parts of the WSDL are shown):

```xml
<binding name="TraderServiceSoapBinding" ...
  <operation name="sell" ...
  <operation name="buy" ...
</binding>
```

### 6.2.3 Writing the Java Client Application Code to Invoke a Web Service

In the following code example, a Java application invokes a Web service operation. The client application takes a single argument: the WSDL of the Web service. The application then uses standard JAX-RPC API code and the Web service-specific implementation of the Service interface, generated by clientgen, to invoke an operation of the Web service.

The example also shows how to invoke an operation that has a user-defined data type (examples.webservices.complex.BasicStruct) as an input parameter and return value. The clientgen Ant task automatically generates the Java code for this user-defined data type.

```java
package examples.webservices.simple_client;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
// import the BasicStruct class, used as a param and return value of the // echoComplexType operation. The class is generated automatically by // the clientgen Ant task.
import examples.webservices.complex.BasicStruct;
/**
* This is a simple Java client application that invokes the * the echoComplexType operation of the ComplexService Web service.
*/
public class Main {
  public static void main(String[] args)
throws ServiceException, RemoteException {
    ComplexService service = new ComplexService_Impl (args[0] + "?WSDL" );
    ComplexPortType port = service.getComplexServicePort();
    BasicStruct in = new BasicStruct();
    in.setIntValue(999);
    in.setStringValue("Hello Struct");
    BasicStruct result = port.echoComplexType(in);
    System.out.println("echoComplexType called. Result: " + result.getIntValue()
+ ", " + result.getStringValue());
  }
}
```
In the preceding example:

- The following code shows how to create a `ComplexPortType` stub:

```java
ComplexService service = new ComplexService_Impl (args[0] + "?WSDL");
ComplexPortType port = service.getComplexServicePort();
```

The `ComplexService_Impl` stub factory implements the JAX-RPC `Service` interface. The constructor of `ComplexService_Impl` creates a stub based on the provided WSDL URI `(args[0] + "?WSDL")`. The `getComplexServicePort()` method is used to return an instance of the `ComplexPortType` stub implementation.

- The following code shows how to invoke the `echoComplexType` operation of the `ComplexService` Web service:

```java
BasicStruct result = port.echoComplexType(in);
```

The `echoComplexType` operation returns the user-defined data type called `BasicStruct`.

The method of your application that invokes the Web service operation must throw or catch `java.rmi.RemoteException` and `javax.xml.rpc.ServiceException`, both of which are thrown from the generated JAX-RPC stubs.

### 6.2.4 Compiling and Running the Client Application

Add `javac` tasks to the `build-client` target in the `build.xml` file to compile all the Java files (both of your client application and those generated by `clientgen`) into class files, as shown by the **bold** text in the following example:

```xml
<target name="build-client">
    <clientgen
        wsd1="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
        destDir="clientclasses"
        packageName="examples.webservices.simple_client"
        type="JAXRPC"/>
    <javac
        srcdir="clientclasses"
        destdir="clientclasses"
        includes="**/*.java"/>
    <javac
        srcdir="src"
        destdir="clientclasses"
        includes="examples/webservices/simple_client/*.java"/>
</target>
```

In the example, the first `javac` task compiles the Java files in the `clientclasses` directory that were generated by `clientgen`, and the second `javac` task compiles the Java files in the `examples/webservices/simple_client` subdirectory of the current directory, where it is assumed your Java client application source is located.

In the preceding example, the `clientgen`-generated Java source files and the resulting compiled classes end up in the same directory (`clientclasses`). Although this might be adequate for prototyping, it is often a best practice to keep source code (even generated code) in a different directory from the compiled classes. To do this, set the `destdir` for both `javac` tasks to a directory different from the `srcdir` directory. You must also copy the following `clientgen`-generated files from `clientgen`'s destination directory to `javac`'s destination directory, keeping the same subdirectory hierarchy in the destination:
Invoking a Web Service from a Java SE Client

packageName/ServiceName_internaldd.xml
packageName/ServiceName_java_wSDL_mapping.xml
packageName/ServiceName_saved_wSDL.wsdl

where packageName refers to the subdirectory hierarchy that corresponds to the package of the generated JAX-RPC stubs and ServiceName refers to the name of the Web service.

To run the client application, add a run target to the build.xml that includes a call to the java task, as shown below:

```xml
<path id="client.class.path">
  <pathelement path="clientclasses"/>
  <pathelement path="${java.class.path}"/>
</path>
<target name="run">
  <java
    fork="true"
    classname="examples.webServices.simple_client.Main"
    failonerror="true" >
    <classpath refid="client.class.path"/>
    <arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService" />
  </java>
</target>
```

The path task adds the clientclasses directory to the CLASSPATH. The run target invokes the Main application, passing it the URL of the deployed Web service as its single argument.

See Section 6.2.5, "Sample Ant Build File for a Java Client" for a full sample build.xml file that contains additional targets from those described in this procedure, such as clean.

Rerun the build-client target to regenerate the artifacts and recompile into classes, then execute the run target to invoke the echoStruct operation:

```bash
prompt> ant build-client run
```

You can use the build-client and run targets in the build.xml file to iteratively update, rebuild, and run the Java client application as part of your development process.

6.2.5 Sample Ant Build File for a Java Client

The following example shows a complete build.xml file for generating and compiling a Java client. See Section 6.2.1, "Using the clientgen Ant Task To Generate Client Artifacts" and Section 6.2.4, "Compiling and Running the Client Application" for explanations of the sections in bold.

```xml
<project name="webservices-simple_client" default="all">
  <!-- set global properties for this build -->
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="example-output" value="output" />
  <property name="clientclass-dir" value="${example-output}/clientclass" />
  <path id="client.class.path">
    <pathelement path="${clientclass-dir}"/>
    <pathelement path="${java.class.path}"/>
  </path>
  <taskdef name="clientgen"
    classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
  <target name="clean">
    <path id="client.class.path">
      <pathelement path="${clientclass-dir}"/>
      <pathelement path="${java.class.path}"/>
    </path>
  </target>
</project>
```
6.3 Invoking a Web Service from Another Web Service

Invoking a Web service from within a WebLogic Web service is similar to invoking one from another Java application, as described in Section 6.2, "Invoking a Web Service from a Java SE Client." However, instead of using the clientgen Ant task to generate the JAX-RPC stubs of the Web service to be invoked, you use the <clientgen> child element of the <jws> element, inside the jwsc Ant task that compiles the invoking Web service. In the JWS file that invokes the other Web service, however, you still use the same standard JAX-RPC APIs to get Service and PortType instances to invoke the Web service operations.

It is assumed that you have read and understood Section 6.2, "Invoking a Web Service from a Java SE Client." It is also assumed that you use Ant in your development environment to build your client application, compile Java files, and so on, and that you have an existing build.xml that builds a Web service that you want to update to invoke another Web service.

The following list describes the changes you must make to the build.xml file that builds your client Web service, which will invoke another Web service. See Section 6.3.1, "Sample build.xml File for a Web Service Client" for the full sample build.xml file:

- Add a <clientgen> child element to the <jws> element that specifies the JWS file that implements the Web service that invokes another Web service. Set the required wsdl attribute to the WSDL of the Web service to be invoked. Set the required packageName attribute to the package into which you want the JAX-RPC client stubs to be generated.

The following list describes the changes you must make to the JWS file that implements the client Web service; see Section 6.3.2, "Sample JWS File That Invokes a Web Service" for the full JWS file example.
Invoking a Web Service from Another Web Service

- Import the files generated by the `<clientgen>` child element of the `jwsc` Ant task. These include the JAX-RPC stubs of the invoked Web service, as well as the Java representation of any user-defined data types used as parameters or return values in the operations of the invoked Web service.

  **Note:** The user-defined data types are generated into a package based on the XML Schema of the data type in the WSDL, not in the package specified by `<clientgen>`. The JAX-RPC stubs, however, use the package name specified by the `packageName` attribute of the `<clientgen>` element.

- Update the method that contains the invoke of the Web service to either throw or catch both `java.rmi.RemoteException` and `javax.xml.rpc.ServiceException`.

- Get the `Service` and `PortType` JAX-RPC stubs implementation and invoke the operation on the port as usual; see Section 6.2.3, "Writing the Java Client Application Code to Invoke a Web Service" for details.

### 6.3.1 Sample build.xml File for a Web Service Client

The following sample `build.xml` file shows how to create a Web service that itself invokes another Web service; the relevant sections that differ from the `build.xml` for building a simple Web service that does not invoke another Web service are shown in **bold**.

The `build-service` target in this case is very similar to a target that builds a simple Web service; the only difference is that the `jwsc` Ant task that builds the invoking Web service also includes a `<clientgen>` child element of the `<jws>` element so that `jwsc` also generates the required JAX-RPC client stubs.

```xml
<project name="webservices-service_to_service" default="all">
  <!-- set global properties for this build -->
  <property name="wls.username" value="weblogic" />
  <property name="wls.password" value="weblogic" />
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="wls.server.name" value="myserver" />
  <property name="ear.deployed.name" value="ClientServiceEar" />
  <property name="example-output" value="output" />
  <property name="ear-dir" value="${example-output}/ClientServiceEar" />
  <property name="clientclass-dir" value="${example-output}/clientclasses" />
  <path id="client.class.path">
    <pathelement path="${clientclass-dir}"/>
    <pathelement path="${java.class.path}"/>
  </path>
  <taskdef name="jwsc" classname="weblogic.wsee.tools.anttasks.JwscTask" />
  <taskdef name="clientgen" classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
  <taskdef name="wldeploy" classname="weblogic.ant.taskdefs.management.WLDeploy"/>
  <target name="all" depends="clean,build-service,deploy,client" />
  <target name="clean" depends="undeploy">
    <delete dir="${example-output}"/>
  </target>
  <target name="build-service">
    <jwsc srcdir="src"/>
  </target>
</project>
```
6.3.2 Sample JWS File That Invokes a Web Service

The following sample JWS file, called ClientServiceImpl.java, implements a Web service called ClientService that has an operation that in turn invokes the echocomplexType operation of a Web service called ComplexService. This operation has a user-defined data type (BasicStruct) as both a parameter and a return value. The relevant code is shown in bold and described after the example.
package examples.webservices.service_to_service;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;
// Import the BasicStruct data type, generated by clientgen and used
// by the ComplexService Web Service
import examples.webservices.complex.BasicStruct;
// Import the JAX-RPC Stubs for invoking the ComplexService Web Service.
// Stubs generated by clientgen
import examples.webservices.service_to_service.ComplexPortType;
import examples.webservices.service_to_service.ComplexService_Impl;
import examples.webservices.service_to_service.ComplexService;
@WebService(name="ClientPortType", serviceName="ClientService",
targetNamespace="http://examples.org")
@WLHttpTransport(contextPath="ClientService", serviceUri="ClientService",
portName="ClientServicePort")
public class ClientServiceImpl {
    @WebMethod()
    public String callComplexService(BasicStruct input, String serviceUrl)
        throws ServiceException, RemoteException
    {
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePort();
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePortTypePort();
        // Invoke the echoComplexType operation of ComplexService
        BasicStruct result = port.echoComplexType(input);
        System.out.println("Invoked ComplexPortType.echoComplexType.");
        return "Invoke went okay!  Here's the result: '" + result.getIntValue() + ",
        " + result.getStringValue() + ";"
    }
}

Follow these guidelines when programming the JWS file that invokes another Web
service; code snippets of the guidelines are shown in bold in the preceding example:

- Import any user-defined data types that are used by the invoked Web service. In
  this example, the ComplexService uses the BasicStruct JavaBean:
    import examples.webservices.complex.BasicStruct;

- Import the JAX-RPC stubs of the ComplexService Web service; the stubs are
  generated by the <cliengen> child element of <jws>:
    import examples.webservices.service_to_service.ComplexPortType;
    import examples.webservices.service_to_service.ComplexService_Impl;
    import examples.webservices.service_to_service.ComplexService;

- Ensure that your client Web service throws or catches ServiceException and
  RemoteException:
    throws ServiceException, RemoteException

- Create the JAX-RPC Service and PortType instances for the ComplexService:
    ComplexService service = new
    ComplexService_Impl(serviceUrl + "?WSDL");
    ComplexPortType port = service.getComplexServicePortTypePort();
6.4 Using a Stand-Alone Client JAR File When Invoking Web Services

It is assumed in this document that, when you invoke a Web service using the client-side artifacts generated by the clientgen or wsdlc Ant tasks, you have the entire set of WebLogic Server classes in your CLASSPATH. If, however, your computer does not have WebLogic Server installed, you can still invoke a Web service by using the stand-alone WebLogic Web services client JAR file, as described in this section.

The standalone client JAR file supports basic client-side functionality, such as:

- Use with client-side artifacts created by both the clientgen Ant tasks
- Processing SOAP messages
- Using client-side SOAP message handlers
- Using MTOM
- Invoking JAX-RPC Web services
- Using SSL

The stand-alone client JAR file does not, however, support invoking Web services that use the following advanced features:

- Web services reliable SOAP messaging
- Message-level security (WS-Security)
- Conversations
- Asynchronous request-response
- Buffering
- JMS transport

To use the stand-alone WebLogic Web services client JAR file with your client application, follow these steps:

1. Copy the file WL_HOME/server/lib/wseeclient.zip from the computer hosting WebLogic Server to the client computer, where WL_HOME refers to the WebLogic Server installation directory, such as /Oracle/Middleware/wlserver_10.3.

2. Unzip the wseeclient.zip file into the appropriate directory. For example, you might unzip the file into a directory that contains other classes used by your client application.

3. Add the wseeclient.jar file (unzipped from the wseeclient.zip file) to your CLASSPATH.

---

**Note:** Also be sure that your CLASSPATH includes the JAR file that contains the Ant classes (ant.jar). This JAR file is typically located in the lib directory of the Ant distribution.
6.5 Using a Proxy Server When Invoking a Web Service

You can use a proxy server to proxy requests from a client application to an application server (either WebLogic or non-WebLogic) that hosts the invoked Web service. You typically use a proxy server when the application server is behind a firewall. There are two ways to specify the proxy server in your client application: programatically using the WebLogic HttpTransportInfo API or using system properties.

6.5.1 Using the HttpTransportInfo API to Specify the Proxy Server

You can programatically specify within the Java client application itself the details of the proxy server that will proxy the Web service invoke by using the standard java.net.* classes and the WebLogic-specific HttpTransportInfo API. You use the java.net classes to create a Proxy object that represents the proxy server, and then use the WebLogic API and properties to set the proxy server on the JAX-RPC stub, as shown in the following sample client that invokes the echo operation of the HttpProxySampleService Web service. The code in bold is described after the example:

```java
package dev2dev.proxy.client;
import java.net.Proxy;
import java.net.InetSocketAddress;
import weblogic.wsee.connection.transport.http.HttpTransportInfo;
/**
 * Sample client to invoke a service through a proxy server via
 * programmatic API
 */
public class HttpProxySampleClient {
    public static void main(String[] args) throws Throwable{
        assert args.length == 5;
        String endpoint = args[0];
        String proxyHost = args[1];
        String proxyPort = args[2];
        String user = args[3];
        String pass = args[4];
        //create service and port
        HttpProxySampleService service = new HttpProxySampleService_Impl();
        HttpProxySamplePortType port = service.getHttpProxySamplePortTypeSoapPort();
        //set endpoint address
        ((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, endpoint);
        //set proxy server info
        Proxy p = new Proxy(Proxy.Type.HTTP, new InetSocketAddress(proxyHost,
                            Integer.parseInt(proxyPort)));
        HttpTransportInfo info = new HttpTransportInfo();
        info.setProxy(p);
        ((Stub)port)._setProperty("weblogic.wsee.connection.transportinfo",info);
        //set proxy-authentication info
        ((Stub)port)._setProperty("weblogic.webservice.client.proxyusername",user);
        ((Stub)port)._setProperty("weblogic.webservice.client.proxypassword",pass);
        //invoke
        String s = port.echo("Hello World!");
        System.out.println("echo: " + s);
    }
}
```

The sections of the preceding example to note are as follows:

- Import the required java.net.* classes:
import java.net.Proxy;
import java.net.InetSocketAddress;

■ Import the WebLogic HttpTransportInfo API:
import weblogic.wsee.connection.transport.http.HttpTransportInfo;

■ Create a Proxy object that represents the proxy server:
Proxy p = new Proxy(Proxy.Type.HTTP, new InetSocketAddress(proxyHost, Integer.parseInt(proxyPort)));

The proxyHost and proxyPort arguments refer to the host computer and port of the proxy server.

■ Create an HttpTransportInfo object and use the setProxy() method to set the proxy server information:
HttpTransportInfo info = new HttpTransportInfo();
info.setProxy(p);

■ Use the weblogic.wsee.connection.transportinfo WebLogic stub property to set the HttpTransportInfo object on the JAX-RPC stub:
((Stub)port)._setProperty("weblogic.wsee.connection.transportinfo",info);

■ Use weblogic.webservice.client.proxyusername and weblogic.webservice.client.proxypassword WebLogic-specific stub properties to specify the username and password of a user who is authenticated to access the proxy server:
((Stub)port)._setProperty("weblogic.webservice.client.proxyusername",user);
((Stub)port)._setProperty("weblogic.webservice.client.proxypassword",pass);

Alternatively, you can use the setProxyUsername() and setProxyPassword() methods of the HttpTransportInfo API to set the proxy username and password, as shown in the following example:
info.setProxyUsername("juliet".getBytes());
info.setProxyPassword("secret".getBytes());

6.5.2 Using System Properties to Specify the Proxy Server
To use system properties to specify the proxy server, write your client application in the standard way, and then specify system properties when you execute the client application.

You have a choice of using standard Java system properties or historical WebLogic properties. If the proxySet system property is set to false (proxySet=false), proxy properties will be ignored and no proxy will be used.

The following table summarizes the Java system properties. In this case, the proxySet system property must not be set.
Using a Proxy Server When Invoking a Web Service

The following excerpt from an Ant build script shows an example of setting Java system properties when invoking a client application called `clients.InvokeMyService`:

```xml
<target name="run-client">
  <java fork="true"
    classname="clients.InvokeMyService"
    failonerror="true">
    <classpath refid="client.class.path"/>
    <arg line="${http-endpoint}"/>
    <jvmarg line="-Dhttp.proxyHost=${proxy-host}
      -Dhttp.proxyPort=${proxy-port}
      -Dhttp.nonProxyHosts=${mydomain}"/>
  </java>
</target>
```

The following table summarizes the WebLogic system properties. In this case, the `proxySet` system property must be set to `true`.

**Table 6–4 WebLogic System Properties Used to Specify the Proxy Server**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxySet=true</td>
<td>Flag that specifies that the historical WebLogic proxy properties should be used.</td>
</tr>
<tr>
<td>proxyHost=proxyHost</td>
<td>Name of the host computer on which the proxy server is running.</td>
</tr>
<tr>
<td>proxyPort=proxyPort</td>
<td>Port to which the proxy server is listening.</td>
</tr>
<tr>
<td>weblogic.webservice.client.proxyusername=USERNAME</td>
<td>Username used to access the proxy server.</td>
</tr>
<tr>
<td>weblogic.webservice.client.proxypassword=PASSWORD</td>
<td>Password used to access the proxy server.</td>
</tr>
</tbody>
</table>

The following excerpt from an Ant build script shows an example of setting WebLogic system properties when invoking a client application called `clients.InvokeMyService`:

```xml
<target name="run-client">
  <java fork="true"
    classname="clients.InvokeMyService"
    failonerror="true">
    <classpath refid="client.class.path"/>
    <arg line="${http-endpoint}"/>
    <jvmarg line=""/>
    <jvmarg line="-Dhttp.proxyHost=${proxy-host}
      -Dhttp.proxyPort=${proxy-port}
      -Dhttp.nonProxyHosts=${mydomain}"/>
  </java>
</target>
```
6.6 Client Considerations When Redeploying a Web Service

WebLogic Server supports production redeployment, which means that you can deploy a new version of an updated WebLogic Web service alongside an older version of the same Web service.

WebLogic Server automatically manages client connections so that only new client requests are directed to the new version. Clients already connected to the Web service during the redeployment continue to use the older version of the service until they complete their work, at which point WebLogic Server automatically retires the older Web service. If the client is connected to a conversational or reliable Web service, its work is considered complete when the existing conversation or reliable messaging sequence is explicitly ended by the client or because of a timeout.

You can continue using the old client application with the new version of the Web service, as long as the following Web service artifacts have not changed in the new version:

- WSDL that describes the Web service
- WS-Policy files attached to the Web service

If any of these artifacts have changed, you must regenerate the JAX-RPC stubs used by the client application by re-running the clientgen Ant task.

For example, if you change the signature of an operation in the new version of the Web service, then the WSDL file that describes the new version of the Web service will also change. In this case, you must regenerate the JAX-RPC stubs. If, however, you simply change the implementation of an operation, but do not change its public contract, then you can continue using the existing client application.

6.7 WebLogic Web Services Stub Properties

WebLogic Server provides a set of stub properties that you can set in the JAX-RPC Stub used to invoke a WebLogic Web service. Use the Stub._setProperty() method to set the properties, as shown in the following example:

```java
((Stub)port)._setProperty(WLStub.MARSHAL_FORCE_INCLUDE_XSI_TYPE,"true");
```

Most of the stub properties are defined in the WLStub class. See "weblogic.wsee.jaxrpc.WLStub" in the Oracle Fusion Middleware Oracle WebLogic Server API Reference for details.

The following table describes additional stub properties not defined in the WLStub class.
### Table 6–5  Additional Stub Properties

<table>
<thead>
<tr>
<th>Stub Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>weblogic.wsee.transport.connection.timeout</td>
<td>Specifies, in milliseconds, how long a client application that is attempting to invoke a Web service waits to make a connection. After the specified time elapses, if a connection hasn’t been made, the attempt times out.</td>
</tr>
<tr>
<td>weblogic.wsee.transport.read.timeout</td>
<td>Specifies, in milliseconds, how long a client application waits for a response from a Web service it is invoking. After the specified time elapses, if a response hasn’t arrived, the client times out.</td>
</tr>
<tr>
<td>weblogic.wsee.security.bst.serverVerifyCert</td>
<td>Specifies the certificate that the client application uses to validate the signed response from WebLogic Server. By default, WebLogic Server includes the certification used to validate in the response SOAP message itself; if this is not possible, then use this stub property to specify a different one. This stub property applies only to client applications that run inside of a WebLogic Server container, and not to stand-alone client applications. The value of the property is an object of data type java.security.cert.X509Certificate.</td>
</tr>
<tr>
<td>weblogic.wsee.security.bst.serverEncryptCert</td>
<td>Specifies the certificate that the client application uses to encrypt the request SOAP message sent to WebLogic Server. By default, the client application uses the public certificate published in the Web service’s WSDL; if this is not possible, then use this stub property to specify a different one. This stub property applies only to client applications that run inside of a WebLogic Server container, and not to stand-alone client applications. The value of the property is an object of data type java.security.cert.X509Certificate.</td>
</tr>
<tr>
<td>weblogic.wsee.marshal.forceIncludeXsiType</td>
<td>Specifies that the SOAP messages for a Web service operation invoke should include the XML Schema data type of each parameter. By default, the SOAP messages do not include the data type of each parameter. If you set this property to True, the elements in the SOAP messages that describe operation parameters will include an xsi:type attribute to specify the data type of the parameter, as shown in the following example: <a href="">soapenv:Envelope</a> ... &lt;maxResults xsi:type=&quot;xs:int&quot;&gt;10&lt;/maxResults&gt; ... By default (or if you set this property to False), the parameter element would look like the following example: <a href="">soapenv:Envelope</a> ... &lt;maxResults&gt;10&lt;/maxResults&gt; ... Valid values for this property are True and False; default value is False.</td>
</tr>
</tbody>
</table>
6.8 Setting the Character Encoding For the Response SOAP Message

Use the `weblogic.wsee.jaxrpc.WLStub.CHARACTER_SET_ENCODING` property to set the character encoding of the response (outbound) SOAP message. You can set it to the following two values:

- UTF-8
- UTF-16

The following code snippet from a client application shows how to set the character encoding to UTF-16:

```java
Simple port = service.getSimpleSoapPort();
((Stub) port)._setProperty(weblogic.wsee.jaxrpc.WLStub.CHARACTER_SET_ENCODING, 'UTF-16');
port.invokeMethod();
```

See "weblogic.wsee.jaxrpc.WLStub" in the Oracle Fusion Middleware Oracle WebLogic Server API Reference for additional WLStub properties you can set.
This chapter describes how to administer WebLogic Web services using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following topics:

- **Section 7.1, "Overview of WebLogic Web Services Administration Tasks"**
- **Section 7.2, "Administration Tools"**
- **Section 7.3, "Using the Administration Console"**
- **Section 7.4, "Using the Oracle Enterprise Manager Fusion Middleware Control"**
- **Section 7.5, "Using the WebLogic Scripting Tool"**
- **Section 7.6, "Using WebLogic Ant Tasks"**
- **Section 7.7, "Using the Java Management Extensions (JMX)"**
- **Section 7.8, "Using the Java EE Deployment API"**
- **Section 7.9, "Using Work Managers to Prioritize Web Services Work and Reduce Stuck Execute Threads"**

### 7.1 Overview of WebLogic Web Services Administration Tasks

When you use the jwsc Ant task to compile and package a WebLogic Web service, the task packages it as part of an Enterprise Application. The Web service itself is packaged inside the Enterprise application as a Web application WAR file, by default. However, if your JWS file implements a session bean then the Web service is packaged as an EJB JAR file. Therefore, basic administration of Web services is very similar to basic administration of standard Java Platform, Enterprise Edition (Java EE) Version 5 applications and modules. These standard tasks include:

- Installing the Enterprise application that contains the Web service.
- Starting and stopping the deployed Enterprise application.
- Configuring the Enterprise application and the archive file which implements the actual Web service. You can configure general characteristics of the Enterprise application, such as the deployment order, or module-specific characteristics, such as session time-out for Web applications or transaction type for EJBs.
- Creating and updating the Enterprise application’s deployment plan.
- Monitoring the Enterprise application.
- Testing the Enterprise application.

The following administrative tasks are specific to Web services:
7.2 Administration Tools

There are a variety of ways to administer Java EE modules and applications that run on WebLogic Server, including Web services; use the tool that best fits your needs:

- Section 7.3, "Using the Administration Console"
- Section 7.5, "Using the WebLogic Scripting Tool"
- Section 7.6, "Using WebLogic Ant Tasks"
- Section 7.7, "Using the Java Management Extensions (JMX)"
- Section 7.8, "Using the Java EE Deployment API"

7.3 Using the Administration Console

The WebLogic Server Administration Console is a Web browser-based, graphical user interface you use to manage a WebLogic Server domain, one or more WebLogic Server instances, clusters, and applications, including Web services, that are deployed to the server or cluster.

One instance of WebLogic Server in each domain is configured as an Administration Server. The Administration Server provides a central point for managing a WebLogic Server domain. All other WebLogic Server instances in a domain are called Managed Servers. In a domain with only a single WebLogic Server instance, that server functions both as Administration Server and Managed Server. The Administration Server hosts the Administration Console, which is a Web Application accessible from any supported Web browser with network access to the Administration Server.

You can use the System Administration Console to:

- "Install an Enterprise application"
- "Start and stop a deployed Enterprise application"
- "Configure an Enterprise application"
- "Configure Web applications"
- "Configure EJ Bs"
"Create a deployment plan"
"Update a deployment plan"
"Test the modules in an Enterprise application"
"Configure JMS resources for Web service reliable messaging"
"Associate the WS-Policy file with a Web service"
"View the SOAP message handlers of a Web service"
"View the WSDL of a Web service"
"Create a Web service security configuration"

7.3.1 Invoking the Administration Console

To invoke the Administration Console in your browser, enter the following URL:
http://host:port/console

where

- **host** refers to the computer on which the Administration Server is running.
- **port** refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001.

Click the **Help** button, located at the top right corner of the Administration Console, to invoke the Online Help for detailed instructions on using the Administration Console.

The following figure shows the main Administration Console window.

Figure 7–1  WebLogic Server Administration Console Main Window
7.3.2 How Web Services Are Displayed In the Administration Console

Web services are typically deployed to WebLogic Server as part of an Enterprise Application. The Enterprise Application can be either archived as an EAR, or be in exploded directory format. The Web service itself is almost always packaged as a Web Application; the only exception is if your JWS file implements a session bean in which case it is packaged as an EJB. The Web service can be in archived format (WAR or EJB JAR file, respectively) or as an exploded directory.

It is not required that a Web service be installed as part of an Enterprise application; it can be installed as just the Web Application or EJB. However, Oracle recommends that users install the Web service as part of an Enterprise application. The WebLogic Ant task used to create a Web service, jwsc, always packages the generated Web service into an Enterprise application.

To view and update the Web service-specific configuration information about a Web service using the Administration Console, click on the Deployments node in the left pane and, in the Deployments table that appears in the right pane, locate the Enterprise application in which the Web service is packaged. Expand the application by clicking the + node; the Web services in the application are listed under the Web services category. Click on the name of the Web service to view or update its configuration.

The following figure shows how the HelloWorldService Web service, packaged inside the helloWorldEar Enterprise application, is displayed in the Deployments table of the Administration Console.

![WebLogic Server Administration Console Main Window](image)

7.3.3 Creating a Web Services Security Configuration

When a deployed WebLogic Web service has been configured to use message-level security (encryption and digital signatures, as described by the WS-Security specification), the Web services run time determines whether a Web service security configuration is also associated with the service. This security configuration specifies
information such as whether to use an X.509 certificate for identity, whether to use password digests, the keystore to be used for encryption, and so on. A single security configuration can be associated with many Web services.

Because Web services security configurations are domain-wide, you create them from the `domainName > WebService Security` tab of the Administration Console, rather than the `Deployments` tab. The following figure shows the location of this tab.

![Web Service Security Configuration in Administration Console](image)

**Figure 7–3  Web Service Security Configuration in Administration Console**

### 7.3.4 Monitoring Web Services and Clients

You can monitor run-time information for Web service and client such as number of invocations, errors, faults, and so on from the Administration Console.

To monitor a Web service using the Administration Console, click on the `Deployments` node in the left pane and, in the Deployments table that appears in the right pane, locate the Enterprise application in which the Web service is packaged. Expand the application by clicking the `+` node; the Web services in the application are listed under the `Web Services` category. Click on the name of the Web service and click the `Monitoring` tab.

The following table lists the tabs that you can select to monitor Web service information. The pages aggregate the statistics of all the servers on which the Web service is running.

| Table 7–1  Monitoring Web Services |
|-------------------------------|----------------------------------|
| Click this tab . . . | To view . . . |
| Monitoring> General | General statistics about the Web services, including total error and invocations counts. |
| Monitoring> Invocations | Invocation statistics, such as dispatch and execution times and averages. |
| Monitoring> WS-Policy | Policies that are attached to the Web service, organized into the following categories: authentication, authorization, confidentiality, and integrity. |
To monitor a Web service client using the Administration Console, click on the **Deployments** node in the left pane and, in the Deployments table that appears in the right pane, locate the Enterprise application in which the Web service client is packaged. Expand the application by clicking the + node and click on the application module within which the Web service client is located. Click the **Monitoring** tab, then click the **Web Service Clients** tab. The table provides a summary of run-time information for each Web service client. Click the client name in the table to view more information.

**Table 7–2**

<table>
<thead>
<tr>
<th>Click this tab . . .</th>
<th>To view . . .</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitoring&gt; General</td>
<td>General statistics about the Web service clients, including total error and invocations counts. The page displays the Web service client name, its associated Enterprise application and application module, and context root. Error and invocations statistics are aggregated for all servers on which the Web service is running.</td>
</tr>
<tr>
<td>Monitoring&gt; Invocations</td>
<td>Invocation statistics, such as dispatch and execution times and averages.</td>
</tr>
<tr>
<td>Monitoring&gt; WS-Policy</td>
<td>Policies that are attached to the Web service client, organized into the following categories: authentication, authorization, confidentiality, and integrity.</td>
</tr>
<tr>
<td>Monitoring&gt; Servers</td>
<td>Table listing the server on which the client is currently running. Click the client name and then use the tabs in the following steps to view more information about the Web service client on that server.</td>
</tr>
</tbody>
</table>
The Oracle Enterprise Manager Fusion Middleware Control (Fusion Middleware Control) is a web browser-based, graphical user interface that you can use to monitor and administer a farm. A farm is a collection of components managed by Fusion Middleware Control. It can contain Oracle WebLogic Server domains, one or more Managed Servers and the Oracle Fusion Middleware system components that are installed, configured, and running in the domain.

Fusion Middleware Control organizes a wide variety of performance data and administrative functions into distinct, web-based home pages for the farm, Oracle WebLogic Server domain, components, and applications. The Fusion Middleware Control home pages make it easy to locate the most important monitoring data and the most commonly used administrative functions—all from your web browser.

The following figure shows Fusion Middleware Control.

### Table 7-2 (Cont.)

<table>
<thead>
<tr>
<th>Click this tab...</th>
<th>To view...</th>

<tr>
<td>Monitoring&gt; Servers &gt; Operations</td>
<td>List of operations for the Web service client. For each operation, run-time monitoring information is displayed, such as average response, execution, and dispatch times, response, invocation and error counts, and so on. You can customize the information that is shown in the table by clicking <strong>Customize this table</strong>. Click the name of an operation to view more information. <strong>Click the General or Invocations</strong> tab to display general statistics or invocation statistics, respectively, for the selected operation.</td>
</tr>
</tbody>
</table>
For more information about monitoring and testing Web services using the Enterprise Manager, see “Securing and Administering WebLogic Web Services” in Oracle Fusion Middleware Security and Administrator’s Guide for Web Services.

Fusion Middleware Control is available as part of the Oracle Fusion Middleware product; it is not available to you if you purchase the standalone version of Oracle WebLogic Server. For more information about Fusion Middleware Control, see "Getting Started Using Oracle Enterprise Manager Fusion Middleware Control" in Oracle Fusion Middleware Administrator’s Guide.

### 7.5 Using the WebLogic Scripting Tool

The WebLogic Scripting Tool (WLST) is a command-line scripting interface that you can use to interact with and configure WebLogic Server domains and instances, as well as deploy Java EE modules and applications (including Web services) to a particular WebLogic Server instance. Using WLST, system administrators and operators can initiate, manage, and persist WebLogic Server configuration changes.

Typically, the types of WLST commands you use to administer Web services fall under the Deployment category.

For more information on using WLST, see Oracle Fusion Middleware Oracle WebLogic Scripting Tool.

### 7.6 Using WebLogic Ant Tasks

WebLogic Server includes a variety of Ant tasks that you can use to centralize many of the configuration and administrative tasks into a single Ant build script. These Ant tasks can:
7.7 Using the Java Management Extensions (JMX)

A managed bean (MBean) is a Java bean that provides a Java Management Extensions (JMX) interface. JMX is the Java EE solution for monitoring and managing resources on a network. Like SNMP and other management standards, JMX is a public specification and many vendors of commonly used monitoring products support it.

WebLogic Server provides a set of MBeans that you can use to configure, monitor, and manage WebLogic Server resources through JMX. WebLogic Web services also have their own set of MBeans that you can use to perform some Web service administrative tasks.

There are two types of MBeans: run-time (for read-only monitoring information) and configuration (for configuring the Web service after it has been deployed).

The configuration Web services MBeans are:

- WebserviceSecurityConfigurationMBean
- WebserviceCredentialProviderMBean
- WebserviceSecurityMBean
- WebserviceSecurityTokenMBean
- WebserviceTimestampMBean
- WebserviceTokenHandlerMBean

The run-time Web services MBeans are:

- WseeRuntimeMBean
- WseeHandlerRuntimeMBean
- WseePortRuntimeMBean
- WseeOperationRuntimeMBean
- WseePolicyRuntimeMBean

For more information on JMX, see the Oracle Fusion Middleware Oracle WebLogic Server MBean Reference and the following sections in Oracle Fusion Middleware Developing Custom Management Utilities With JMX for Oracle WebLogic Server:

- "Understanding WebLogic Server MBeans"
- "Accessing WebLogic Server MBeans with JMX"
- "Managing a Domain’s Configuration with JMX"
7.8 Using the Java EE Deployment API

In Java EE 5, the Java EE Application Deployment specification (JSR-88), described at http://jcp.org/en/jsr/detail?id=88, defines a standard API that you can use to configure an application for deployment to a target application server environment.

The specification describes the Java EE Deployment architecture, which in turn defines the contracts that enable tools or application programmers to configure and deploy applications on any Java EE platform product. The contracts define a uniform model between tools and Java EE platform products for application deployment configuration and deployment. The Deployment architecture makes it easier to deploy applications: Deployers do not have to learn all the features of many different Java EE deployment tools in order to deploy an application on many different Java EE platform products.

See Oracle Fusion Middleware Deploying Applications to Oracle WebLogic Server for more information.

7.9 Using Work Managers to Prioritize Web Services Work and Reduce Stuck Execute Threads

After a connection has been established between a client application and a Web service, the interactions between the two are ideally smooth and quick, whereby the client makes requests and the service responds in a prompt and timely manner. Sometimes, however, a client application might take a long time to make a new request, during which the Web service waits to respond, possibly for the life of the WebLogic Server instance; this is often referred to as a stuck execute thread. If, at any given moment, WebLogic Server has a lot of stuck execute threads, the overall performance of the server might degrade.

If a particular Web service gets into this state fairly often, you can specify how the service prioritizes the execution of its work by configuring a Work Manager and applying it to the service. For example, you can configure a response time request class (a specific type of Work Manager component) that specifies a response time goal for the Web service.

The following shows an example of how to define a response time request class in a deployment descriptor:

```
<work-manager>
  <name>responsetime_workmanager</name>
  <response-time-request-class>
    <name>my_response_time</name>
    <goal-ms>2000</goal-ms>
  </response-time-request-class>
</work-manager>
```

You can configure the response time request class using the Administration Console, as described in "Work Manager: Response Time: Configuration" in the Oracle Fusion Middleware Oracle WebLogic Server Administration Console Help.

For more information about Work Managers in general and how to configure them for your Web service, see "Using Work Managers to Optimize Scheduled Work" in Oracle Fusion Middleware Configuring Server Environments for Oracle WebLogic Server.
This chapter describes how to upgrade a pre-10.3.x WebLogic Server Web service to run in the Oracle WebLogic Server 11g Release 1 (10.3.x) Web service run-time environment.

This chapter includes the following topics:

- Section 8.1, "Upgrading a 9.2 or 10.0 WebLogic Web Service to 10.3.x"
- Section 8.2, "Upgrading a 9.0 or 9.1 WebLogic Web Service to 10.3.x"
- Section 8.3, "Upgrading an 8.1 WebLogic Web Service to 10.3.x"

Note: 8.1 and 9.2 WebLogic Web services will continue to run, without any changes, on version 10.3.x of WebLogic Server because the associated Web services run time is still supported in this release, although it is deprecated and will be removed from the product in future releases. For this reason, Oracle highly recommends that you follow the instructions in this chapter to upgrade your 8.1 or 9.2 Web service to 10.3.x.

In order for 8.1 Web services to run on version 10.3.x of WebLogic Server, you need to update the following system property:

```java
System.setProperty('javax.xml.soap.SOAPFactory',
  'weblogic.webservice.core.soap.SOAPFactoryImpl');
```

To minimize the impact that this system property settings has on your 10.3.x Web service applications, it is recommended that you deploy the 8.1 Web services and clients on a server that is separate from the 10.3.x Web services and clients.

### 8.1 Upgrading a 9.2 or 10.0 WebLogic Web Service to 10.3.x

No steps are required to upgrade a 9.2 or 10.x WebLogic Web service to 10.3.x; you can redeploy the Web service to WebLogic Server 10.3.x without making any changes or recompiling.

### 8.2 Upgrading a 9.0 or 9.1 WebLogic Web Service to 10.3.x

If your 9.0/9.1 Web service used any of the following features, then you must recompile the Web service before you redeploy it to WebLogic Server 10.3.x:
8.3 Upgrading an 8.1 WebLogic Web Service to 10.3.x

This section describes how to upgrade an 8.1 WebLogic Web service to use the new Version 10.3.x Web services run-time environment. The 10.3.x run time is based on the Web Services for Java EE 1.2 specification at http://www.jcp.org/en/jsr/detail?id=109. The 10.3.x programming model uses standard JDK 1.5 metadata annotations, as specified by the Web Services Metadata for the Java Platform specification (JSR-181) at http://www.jcp.org/en/jsr/detail?id=181.

**Note:** 8.1 WebLogic Web services will continue to run, without any changes, on 10.3.x of WebLogic Server because the 8.1 Web services run time is still supported in 10.3.x, although it is deprecated and will be removed from the product in future releases. For this reason, Oracle highly recommends that you follow the instructions in this chapter to upgrade your 8.1 Web service to 10.3.x.

Upgrading your 8.1 Web service includes the following high-level tasks; the procedures in later sections go into more detail:

- Update the 8.1 Java source code of the Java class or stateless session EJB that implements the Web service so that the source code uses JWS annotations.

  In 10.3.x, WebLogic Web services are implemented using JWS files, which are Java files that contains JWS annotations. The jwsc Ant Task always implements the Web service as a plain Java file unless you explicitly implement javax.ejb.SessionBean in your JWS file. This latter case is not typical. This programming model differs from that of 8.1, where you were required to specify the type of back-end component (Java class or EJB).

- Update the Ant build script that builds the Web service to call the 10.3.x WebLogic Web service Ant task jwsc instead of the 8.1 servicegen task.

In the sections that follow it is assumed that:

- You previously used servicegen to generate your 8.1 Web service and that, more generally, you use Ant scripts in your development environment to iteratively develop Web services and other Java Platform, Enterprise Edition (Java EE) Version 5 artifacts that run on WebLogic Server. The procedures in this section direct you to update existing Ant build.xml files.

- You have access to the Java class or EJB source code for your 8.1 Web service.

This section does not discuss the following topics:

- Upgrading a JMS-implemented 8.1 Web service, because the 10.3.x WebLogic Web services run time does not support JMS-implemented services.
Upgrading Web services from versions previous to 8.1.

Upgrading a client application that invokes an 8.1 Web service to one that invokes a 10.3.x Web service. For details on how to write a client application that invokes a 10.3.x Web service, see Chapter 6, "Invoking Web Services."

8.3.1 Upgrading an 8.1 Java Class-Implemented WebLogic Web Service to 10.3.x: Main Steps

To upgrade an 8.1 Java class-implemented Web service to use the 10.3.x WebLogic Web services run time:

1. Open a command window and set your WebLogic Server 10.3.x environment by executing the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the `bin` subdirectory of your 10.3.x domain directory.
   
The default location of WebLogic Server domains is `MW_HOME/user_projects/domains/domainName`, where `MW_HOME` is the top-level installation directory of the Oracle products and `domainName` is the name of your domain.

2. Create a project directory:
   
   ```sh
   prompt> mkdir /myExamples/upgrade_pojo
   ```

3. Create a `src` directory under the project directory, as well as sub-directories that correspond to the package name of the new 10.3.x JWS file (shown later in this procedure) that corresponds to the old 8.1 Java class:
   
   ```sh
   prompt> cd /myExamples/upgrade_pojo
   prompt> mkdir src/examples/webservices/upgrade_pojo
   ```

4. Copy the old Java class that implements the 8.1 Web service to the `src/examples/webservices/upgrade_pojo` directory of the working directory. Rename the file, if desired.

5. Edit the Java file, as described in the following steps. See the old and new sample Java files in Section 8.3.1.1, "Example of an 8.1 Java File and the Corresponding 10.3.x JWS File" for specific examples.
   
a. If needed, change the package name and class name of the Java file to reflect the new 10.3.x source environment.

b. Add `import` statements to import both the standard and WebLogic-specific JWS annotations.

c. Add, at a minimum, the following JWS annotation:

   ```
   - The standard `@WebService` annotation at the Java class level to specify that the JWS file implements a Web service.
   
   Oracle recommends you also add the following annotations:
   
   - The standard `@SOAPBinding` annotation at the class-level to specify the type of Web service, such as document-literal-wrapped or RPC-encoded.
   
   - The WebLogic-specific `@WLHttpTransport` annotation at the class-level to specify the context and service URIs that are used in the URL that invokes the deployed Web service.
   
   - The standard `@WebMethod` annotation at the method-level for each method that is exposed as a Web service operation.
   ```
See Chapter 4, "Programming the JWS File" for general information about using JWS annotations in a Java file.

d. You might need to add additional annotations to your JWS file, depending on the 8.1 Web service features you want to carry forward to 10.3.x. In 8.1, many of these features were configured with attributes of servicegen. See Section 8.3.3, "Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes" for a table that lists equivalent JWS annotation, if available, for features you enabled in 8.1 using servicegen attributes.

6. Copy the old build.xml file that built the 8.1 Web service to the 10.3.x working directory.

7. Update your Ant build.xml file to execute the jwsc Ant task, along with other supporting tasks, instead of servicegen.

Oracle recommends that you create a new target, such as build-service, in your Ant build file and add the jwsc Ant task call to compile the new JWS file you created in the preceding steps. Once this target is working correctly, you can remove the old servicegen Ant task.

The following procedure lists the main steps to update your build.xml file; for details on the steps, see the standard iterative development process outlined in Chapter 3, "Developing WebLogic Web Services."

See Section 8.3.1.2, "Example of an 8.1 and Updated 10.3.x Ant Build File for Java Class-Implemented Web Services" for specific examples of the steps in the following procedure.

1. Add the jwsc taskdef to the build.xml file.

2. Create a build-service target and add the tasks needed to build the 10.3.x Web service, as described in the following steps.

3. Add the jwsc task to the build file. Set the srdir attribute to the src directory (/myExamples/upgrade_pojo/src, in this example) and the destdir attribute to the root Enterprise application directory you created in the preceding step.

   Set the file attribute of the <jws> child element to the name of the new JWS file, created earlier in this procedure.

   You may need to specify additional attributes to the jwsc task, depending on the 8.1 Web service features you want to carry forward to 10.3.x. In 8.1, many of these features were configured using attributes of servicegen. See Section 8.3.3, "Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes" for a table that describes if there is an equivalent jwsc attribute for features you enabled using servicegen attributes.

8. Execute the build-service Ant target. Assuming all the tasks complete successfully, the resulting Enterprise application contains your upgraded 10.3.x Web service.

See Section 3.9, "Deploying and Undeploying WebLogic Web Services" and Section 3.10, "Browsing to the WSDL of the Web Service" for additional information about deploying and testing your Web service.

Based on the sample Java code shown in the following sections, the URL to invoke the WSDL of the upgraded 10.3.x Web service is:

http://host:port/upgradePOJO/HelloWorld?WSDL
8.3.1.1 Example of an 8.1 Java File and the Corresponding 10.3.x JWS File

Assume that the following sample Java class implemented a 8.1 Web service:

```java
package examples.javaclass;
/**
 * Simple Java class that implements the HelloWorld Web service. It takes
 * as input an integer and a String, and returns a message that includes these
 * two parameters.
 */
public final class HelloWorld81 {
/**
 * Returns a text message that includes the integer and String input
 * parameters.
 */

public String sayHello(int num, String s) {
    System.out.println("sayHello operation has been invoked with arguments "+ s +
    " and "+ num);
    String returnValue = "This message brought to you by the letter "+s+" and the
    number "+num;
    return returnValue;
}
}
```

An equivalent JWS file for a 10.3.x Java class-implemented Web service is shown below, with the differences shown in bold. Note that some of the JWS annotation values are taken from attributes of the 8.1 servicegen Ant task shown in Section 8.3.1.2, "Example of an 8.1 and Updated 10.3.x Ant Build File for Java Class-Implemented Web Services."

```java
package examples.webservices.upgrade_pojo;
// Import standard JWS annotations
import javax.jws.WebService;
import javax.jws.WebMethod;
import javax.jws.soap.SOAPBinding;
// Import WebLogic JWS annotation
import weblogic.jws.WLHttpTransport;
/**
 * Simple Java class that implements the HelloWorld92 Web service. It takes
 * as input an integer and a String, and returns a message that includes these
 * two parameters.
 */
@WebService(name="HelloWorld92PortType", serviceName="HelloWorld",
targetNamespace="http://example.org")
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
use=SOAPBinding.Use.LITERAL,
    parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
@WLHttpTransport(contextPath="upgradePOJO", serviceUri="HelloWorld",
    portName="HelloWorld92Port")
public class HelloWorld92Impl {
/**
 * Returns a text message that includes the integer and String input
 * parameters.
 */

@WebMethod()
public String sayHello(int num, String s) {
    System.out.println("sayHello operation has been invoked with arguments "+ s +
    " and "+ num);
    String returnValue = "This message brought to you by the letter "+s+" and the
```
number " + num;
    return returnValue;
  }
}

### 8.3.1.2 Example of an 8.1 and Updated 10.3.x Ant Build File for Java Class-Implemented Web Services

The following simple `build.xml` file shows the 8.1 way to build a WebLogic Web service using the `servicegen` Ant task; in the example, the Java file that implements the 8.1 Web service has already been compiled into the `examples.javaclass.HelloWorld81` class:

```xml
<project name="javaclass-webservice" default="all" basedir=".">
  <!-- set global properties for this build -->
  <property name="source" value="./"/>
  <property name="build" value="${source}/build"/>
  <property name="war_file" value="HelloWorldWS.war"/>
  <property name="ear_file" value="HelloWorldApp.ear"/>
  <property name="namespace" value="http://examples.org"/>
  <target name="all" depends="clean, ear">
    <clean dir="${build}"/>
    <servicegen
      destEar="${build}/${ear_file}";
      warName="${war_file}">
      <service
        javaClassComponents="examples.javaclass.HelloWorld81"
        targetNamespace="${namespace}"
        serviceName="HelloWorld"
        serviceURI="/HelloWorld"
        generateTypes="True"
        expandMethods="True">
      </service>
    </servicegen>
  </target>
</project>
```

An equivalent `build.xml` file that calls the `jwsc` Ant task to build a 10.3.x Web service is shown below, with the relevant tasks discussed in this section in bold. In the example, the new JWS file that implements the 10.3.x Web service is called `HelloWorld92Impl.java`:

```xml
<project name="webservices-upgrade_pojo" default="all">
  <!-- set global properties for this build -->
  <property name="wls.username" value="weblogic"/>
  <property name="wls.password" value="weblogic"/>
  <property name="wls.hostname" value="localhost"/>
  <property name="wls.port" value="7001"/>
  <property name="wls.server.name" value="myserver"/>
  <property name="ear.deployed.name" value="upgradePOJOEar"/>
  <property name="example-output" value="output"/>
  <property name="ear-dir" value="${example-output}/upgradePOJOEar"/>
  <taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask"/>
  <taskdef name="wldeploy">
8.3.2 Upgrading an 8.1 EJB-Implemented WebLogic Web Service to 10.3.x: Main Steps

The following procedure describes how to upgrade an 8.1 EJB-implemented Web service to use the 10.3.x WebLogic Web services run time.

The 10.3.x Web services programming model is quite different from the 8.1 model in that it hides the underlying implementation of the Web service. Rather than specifying up front that you want the Web service to be implemented by a Java class or an EJB, the jwsc Ant task always picks a plain Java class implementation, unless you have explicitly implemented javax.ejb.SessionBean in the JWS file, which is not typical. For this reason, the following procedure does not show how to import EJB classes or use EJBGen, even though the 8.1 Web service was explicitly implemented with an EJB. Instead, the procedure shows how to create a standard JWS file that is the 10.3.x equivalent to the 8.1 EJB-implemented Web service.

1. Open a command window and set your 10.3.x WebLogic Server environment by executing the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your 10.3.x domain directory.

   The default location of WebLogic Server domains is $MW_HOME/user_projects/domains/domainName, where $MW_HOME is the top-level installation directory of the Oracle products and domainName is the name of your domain.

2. Create a project directory:

   prompt> mkdir /myExamples/upgrade_ejb

3. Create a src directory under the project directory, as well as sub-directories that correspond to the package name of the new 10.3.x JWS file (shown later on in this procedure) that corresponds to your 8.1 EJB implementation:

   prompt> cd /myExamples/upgrade_ejb
prompt> mkdir src/examples/webservices/upgrade_ejb

4. Copy the 8.1 EJB Bean file that implemented `javax.ejb.SessionBean` to the `src/examples/webservices/upgrade_ejb` directory of the working directory. Rename the file, if desired.

**Note:** You do not need to copy over the 8.1 Home and Remote EJB files.

5. Edit the EJB Bean file, as described in the following steps. See the old and new sample Java files in Section 8.3.2.1, "Example of 8.1 EJB Files and the Corresponding 10.3.x JWS File" for specific examples.

a. If needed, change the package name and class name of the Java file to reflect the new 10.3.x source environment.

b. Optionally remove the import statements that import the EJB classes (`javax.ejb.*`). These classes are no longer needed in the upgraded JWS file.

c. Add import statements to import both the standard and WebLogic-specific JWS annotations.

d. Ensure that the JWS file does not implement `javax.ejb.SessionBean` anymore by removing the implements `SessionBean` code from the class declaration.

e. Remove all the EJB-specific methods:
   - `ejbActivate()`
   - `ejbRemove()`
   - `ejbPassivate()`
   - `ejbCreate()`

f. Add, at a minimum, the following JWS annotation:
   - The standard `@WebService` annotation at the Java class level to specify that the JWS file implements a Web service.

   Oracle recommends you also add the following annotations:
   - The standard `@SOAPBinding` annotation at the class-level to specify the type of Web service, such as document-literal-wrapped or RPC-encoded.
   - The WebLogic-specific `@WLHttpTransport` annotation at the class-level to specify the context and service URIs that are used in the URL that invokes the deployed Web service.
   - The standard `@WebMethod` annotation at the method-level for each method that is exposed as a Web service operation.

   See Chapter 4, "Programming the JWS File" for general information about using JWS annotations in a Java file.

g. You might need to add additional annotations to your JWS file, depending on the 8.1 Web service features you want to carry forward to 10.3.x. In 8.1, many of these features were configured using attributes of `servicegen`. See Section 8.3.3, "Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes" for a table that lists equivalent JWS annotation, if available, for features you enabled in 8.1 using `servicegen` attributes.
6. Copy the old `build.xml` file that built the 8.1 Web service to the 10.3.x working directory.

7. Update your Ant `build.xml` file to execute the `jwsc` Ant task, along with other supporting tasks, instead of `servicegen`.

Oracle recommends that you create a new target, such as `build-service`, in your Ant build file and add the `jwsc` Ant task call to compile the new JWS file you created in the preceding steps. Once this target is working correctly, you can remove the old `servicegen` Ant task.

The following procedure lists the main steps to update your `build.xml` file; for details on the steps, see the standard iterative development process outlined in Section 8.3.2.2, "Example of an 8.1 and Updated 10.3.x Ant Build File for an 8.1 EJB-Implemented Web Service" for specific examples of the steps in the following procedure.

a. Add the jwsc taskdef to the `build.xml` file.

b. Create a `build-service` target and add the tasks needed to build the 10.3.x Web service, as described in the following steps.

c. Add the `jwsc` task to the build file. Set the `srdir` attribute to the src directory (`/myExamples/upgrade_ejb/src`, in this example) and the `destdir` attribute to the root Enterprise application directory you created in the preceding step.

Set the `file` attribute of the `<jws>` child element to the name of the new JWS file, created earlier in this procedure.

You may need to specify additional attributes to the `jwsc` task, depending on the 8.1 Web service features you want to carry forward to 10.3.x. In 8.1, many of these features were configured using attributes of `servicegen`. See Section 8.3.3, "Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes" for a table that indicates whether there is an equivalent `jwsc` attribute for features you enabled using `servicegen` attributes.

8. Execute the `build-service` Ant target. Assuming all tasks complete successfully, the resulting Enterprise application contains your upgraded 10.3.x Web service.

See Section 3.9, "Deploying and Undeploying WebLogic Web Services" and Section 3.10, "Browsing to the WSDL of the Web Service" for additional information about deploying and testing your Web service.

Based on the sample Java code shown in the following sections, the URL to invoke the WSDL of the upgraded 10.3.x Web service is:

```
http://host:port/upgradeEJB/HelloWorldService?WSDL
```

### 8.3.2.1 Example of 8.1 EJB Files and the Corresponding 10.3.x JWS File

Assume that the Bean, Home, and Remote classes and interfaces, shown in the next three sections, implemented the 8.1 stateless session EJB which in turn implemented an 8.1 Web service.

The equivalent 10.3.x JWS file is shown in Section 8.3.2.1.4, "Equivalent 10.3.x JWS File." The differences between the 8.1 and 10.3.x classes are shown in bold. Note that some of the JWS annotation values are taken from attributes of the 8.1 `servicegen` Ant task shown in Section 8.3.2.2, "Example of an 8.1 and Updated 10.3.x Ant Build File for an 8.1 EJB-Implemented Web Service."

#### 8.3.2.1.1 8.1 SessionBean Class

```java
package examples.statelessSession;
```
import javax.ejb.CreateException;
import javax.ejb.SessionBean;
import javax.ejb.SessionContext;

/**
 * HelloWorldBean is a stateless session EJB. It has a single method,
 * sayHello(), that takes an integer and a String and returns a String.
 * <p>
 * The sayHello() method is the public operation of the Web service based on
 * this EJB.
 */
public class HelloWorldBean81 implements SessionBean {
    private static final boolean VERBOSE = true;
    private SessionContext ctx;
    // You might also consider using WebLogic's log service
    private void log(String s) {
        if (VERBOSE) System.out.println(s);
    }
    /**
     * Single EJB business method.
     */
    public String sayHello(int num, String s) {
        System.out.println("sayHello in the HelloWorld EJB has "+
            "been invoked with arguments " + s + " and " + num);
        String returnValue = "This message brought to you by the "+
            "letter " + s + " and the number " + num;
        return returnValue;
    }
    /**
     * This method is required by the EJB Specification,
     * but is not used by this example.
     * 
     */
    public void ejbActivate() {
        log("ejbActivate called");
    }
    /**
     * This method is required by the EJB Specification,
     * but is not used by this example.
     * 
     */
    public void ejbRemove() {
        log("ejbRemove called");
    }
    /**
     * This method is required by the EJB Specification,
     * but is not used by this example.
     * 
     */
    public void ejbPassivate() {
        log("ejbPassivate called");
    }
    /**
     * Sets the session context.
     * 
     * @param ctx SessionContext Context for session
     */
    public void setSessionContext(SessionContext ctx) {
        log("setSessionContext called");
        this.ctx = ctx;
    }
}
/**
  * This method is required by the EJB Specification,
  * but is not used by this example.
  */
public void ejbCreate () throws CreateException {
  log("ejbCreate called");
}

8.3.2.1.2 8.1 Remote Interface
package examples.statelessSession;
import java.rmi.RemoteException;
import javax.ejb.EJBObject;
/**
  * The methods in this interface are the public face of HelloWorld.
  * The signatures of the methods are identical to those of the EJBean, except
  * that these methods throw a java.rmi.RemoteException.
  */
public interface HelloWorld81 extends EJBObject {
  /**
   * Simply says hello from the EJB
   *
   * @param num               int number to return
   * @param s                 String string to return
   * @return                  String returnValue
   * @exception               RemoteException if there is
   *                          a communications or systems failure
   */
  String sayHello(int num, String s)
    throws RemoteException;
}

8.3.2.1.3 8.1 EJB Home Interface
package examples.statelessSession;
import java.rmi.RemoteException;
import javax.ejb.CreateException;
import javax.ejb.EJBHome;
/**
  * This interface is the Home interface of the HelloWorld stateless session EJB.
  */
public interface HelloWorldHome81 extends EJBHome {
  /**
    * This method corresponds to the ejbCreate method in the
    * HelloWorldBean81.java file.
    */
  HelloWorld81 create()
    throws CreateException, RemoteException;
}

8.3.2.1.4 Equivalent 10.3.x JWS File
The differences between the 8.1 and 10.3.x files are shown in bold. The value of some JWS annotations are taken from attributes of the 8.1 servicegen Ant task shown in Section 8.3.2.2, "Example of an 8.1 and Updated 10.3.x Ant Build File for an 8.1 EJB-Implemented Web Service."

package examples.webservices.upgrade_ejb;
// Import the standard JWS annotations
import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.soap.SOAPBinding;
// Import the WebLogic specific annotation
import weblogic.jws.WLHttpTransport;
// Class-level annotations
@WebService(name="HelloWorld92PortType", serviceName="HelloWorldService",
targetNamespace="http://example.org")
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
use=SOAPBinding.Use.LITERAL,
parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
@WLHttpTransport(contextPath="upgradeEJB", serviceUri="HelloWorldService",
portName="HelloWorld92Port")

/**
 * HelloWorld92Impl is the JWS equivalent of the HelloWorld81 EJB that
 * implemented the 8.1 Web Service. It has a single method,
 * sayHello(), that takes an integer and a String and returns a String.
 */
public class HelloWorld92Impl {
    /** the sayHello method will become the public operation of the Web
     * Service.
     */
    @WebMethod()
    public String sayHello(int num, String s) {
        System.out.println("sayHello in the HelloWorld92 Web Service has " +
                        "been invoked with arguments " + s + " and " + num);
        String returnValue = "This message brought to you by the " +
                            "letter " + s + " and the number " + num;
        return returnValue;
    }
}

8.3.2.2 Example of an 8.1 and Updated 10.3.x Ant Build File for an 8.1
EJB-Implemented Web Service

The following simple build.xml file shows the 8.1 way to build an EJB-implemented
WebLogic Web service using the servicegen Ant task. Following this example is an
equivalent build.xml file that calls the jwsc Ant task to build a 10.3.x Web service.

<project name="ejb-webservice" default="all" basedir=".">
    <!-- set global properties for this build -->
    <property name="source" value="."/>
    <property name="build" value="${source}/build"/>
    <property name="ejb_file" value="HelloWorldWS.jar" />
    <property name="war_file" value="HelloWorldWS.war" />
    <property name="ear_file" value="HelloWorldApp.ear" />
    <property name="namespace" value="http://examples.org" />
    <target name="all" depends="clean,ear">
        <!-- example of old 8.1 servicegen call to build Web Service -->
        <target name="ejb">
            <delete dir="${build}"/>
        </target>
    </target>
</project>
An equivalent build.xml file that calls the jwsc Ant task to build a 10.3.x Web service is shown below, with the relevant tasks discussed in this section in bold:

```xml
<project name="webservices-upgrade_ejb" default="all">
  <!-- set global properties for this build -->
  <property name="wls.username" value="weblogic" />
  <property name="wls.password" value="weblogic" />
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="wls.server.name" value="myserver" />
  <property name="ear.deployed.name" value="upgradeEJB" />
  <property name="example-output" value="output" />
  <property name="ear-dir" value="${example-output}/upgradeEJB" />

  <taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
  <taskdef name="wldeploy"
    classname="weblogic.ant.taskdefs.management.WLDeploy"/>
  <target name="all" depends="clean,build-service,deploy" />
  <target name="clean" depends="undeploy">
    <delete dir="${example-output}" />
  </target>
  <target name="build-service">
    <jwsc
      srcdir="src"
      destdir="${ear-dir}" />
    <jws file="examples/webservices/upgrade_ejb/HelloWorld92Impl.java" />
  </target>
  <target name="deploy">
    <wldeploy action="deploy" name="${ear.deployed.name}"
      source="${ear-dir}" user="${wls.username}"
      password="${wls.password}" verbose="true"
      adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
  </target>
  <target name="undeploy">
    <wldeploy action="undeploy" name="${ear.deployed.name}"
      failonerror="false"
      user="${wls.username}" password="${wls.password}" verbose="true"
      adminurl="t3://${wls.hostname}:${wls.port}" />
  </target>
</project>
```
Upgrading an 8.1 WebLogic Web Service to 10.3.x

```xml
  targets="$(wls.server.name)" />
</target>
</project>
```

### 8.3.3 Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes

The following table maps the attributes of the 8.1 servicegen Ant task to their equivalent 10.3.x JWS annotation or jwsc attribute.

The attributes listed in the first column are a mixture of attributes of the main servicegen Ant task and attributes of the four child elements of servicegen (service, client, handlerChain, and security).

See "JWS Annotation Reference" and "jwsc" in the Oracle Fusion Middleware WebLogic Web Services Reference for Oracle WebLogic Server for more information about the 10.3.x JWS annotations and jwsc Ant task.

<table>
<thead>
<tr>
<th>servicegen or Child Element of servicegen Attribute</th>
<th>Equivalent JWS Annotation or jwsc Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>contextURI</td>
<td><code>contextPath</code> attribute of the WebLogic-specific @WLHttpTransport annotation.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Because this is a WebLogic-specific annotation, you can use it to generate only a JAX-RPC Web service, and not a JAX-WS Web service.</td>
</tr>
<tr>
<td>destEAR</td>
<td><code>destdir</code> attribute of the jwsc Ant task.</td>
</tr>
<tr>
<td>keepGenerated</td>
<td><code>keepGenerated</code> attribute of the jwsc Ant task.</td>
</tr>
<tr>
<td>mergeWithExistingWS</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>overwrite</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>warName</td>
<td><code>name</code> attribute of the <code>&lt;jws&gt;</code> child element of the jwsc Ant task.</td>
</tr>
<tr>
<td><code>ejbJAR</code> (attribute of the service child element)</td>
<td>No direct equivalent, because the jwsc Ant task generates Web service artifacts from a JWS file, rather than a compiled EJB or Java class.</td>
</tr>
<tr>
<td></td>
<td>Indirect equivalent is the <code>file</code> attribute of the <code>&lt;jws&gt;</code> child element of the jwsc Ant task that specifies the name of the JWS file.</td>
</tr>
<tr>
<td><code>excludeEJBs</code> (attribute of the service child element)</td>
<td>No equivalent.</td>

<tr>
<td><code>expandMethods</code> (attribute of the service child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td><code>generateTypes</code> (attribute of the service child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td><code>ignoreAuthHeader</code> (attribute of the service child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td><code>includeEJBs</code> (attribute of the service child element)</td>
<td>No equivalent.</td>
</tr>
</tbody>
</table>
Table 8–1 (Cont.) Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes

<table>
<thead>
<tr>
<th>servicegen or Child Element of servicegen Attribute</th>
<th>Equivalent JWS Annotation or jwsc Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>javaClassComponents (attribute of the service child element)</td>
<td>No direct equivalent, because the jwsc Ant task generates Web service artifacts from a JWS file, rather than a compiled EJB or Java class. Indirect equivalent is the file attribute of the &lt;jws&gt; child element of the jwsc Ant task that specifies the name of the JWS file.</td>
</tr>
<tr>
<td>JMSAction (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
<tr>
<td>JMSConnectionFactory (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
<tr>
<td>JMSDestination (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
<tr>
<td>JMSDestinationType (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
<tr>
<td>JMSMessageType (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
<tr>
<td>JMSOperationName (attribute of the service child element)</td>
<td>No equivalent because JMS-implemented Web services are not supported in the 10.3.x release.</td>
</tr>
</tbody>
</table>
| protocol (attribute of the service child element) | One of the following WebLogic-specific annotations:  
  - @WLHttpTransport  
  - @WLJmsTransport  
  **Note:** Because these are WebLogic-specific annotations, you can use them to generate only a JAX-RPC Web service, and not a JAX-WS Web service. |
| serviceName (attribute of the service child element) | serviceName attribute of the standard @WebService annotation. |
| serviceURI (attribute of the service child element) | serviceUri attribute of the WebLogic-specific @WLHttpTransport or @WLJmsTransport annotations.  
  **Note:** Because these are WebLogic-specific annotations, you can use them to generate only a JAX-RPC Web service, and not a JAX-WS Web service. |
| style (attribute of service child element) | style attribute of the standard @SOAPBinding annotation. |
| typeMappingFile (attribute of the service child element) | No equivalent. |
| targetNamespace (attribute of the service child element) | targetNamespace attribute of the standard @WebService annotation. |
| userSOAP12 (attribute of the service child element) | value attribute of the WebLogic-specific @weblogic.jws.Binding JWS annotation  
  **Note:** Because this is a WebLogic-specific annotation, you can use it to generate only a JAX-RPC Web service, and not a JAX-WS Web service. |
### Table 8–1 (Cont.) Mapping of servicegen Attributes to JWS Annotations or jwsc Attributes

<table>
<thead>
<tr>
<th>servicegen or Child Element of servicegen Attribute</th>
<th>Equivalent JWS Annotation or jwsc Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>clientJarName (attribute of client child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>packageName (attribute of the client child element)</td>
<td>No direct equivalent.</td>
</tr>
<tr>
<td>saveWSDL (attribute of the client child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>userServerTypes (attribute of the client child element)</td>
<td>No equivalent.</td>
</tr>
<tr>
<td>handlers (attribute of the handlerChain child element)</td>
<td>Standard @HandlerChain or @SOAPMessageHandlers annotation.</td>
</tr>
<tr>
<td>name (attribute of the handlerChain child element)</td>
<td>Standard @HandlerChain or @SOAPMessageHandlers annotation.</td>
</tr>
<tr>
<td>duplicateElimination (attribute of the reliability child element)</td>
<td>No direct equivalent.</td>
</tr>
<tr>
<td>persistDuration (attribute of the reliability child element)</td>
<td>Use WebLogic-specific @Policy attribute to specify a WS-Policy file that contains Web service reliable messaging policy assertions.</td>
</tr>
<tr>
<td>enablePasswordAuth (attribute of the security child element)</td>
<td>Use WebLogic-specific @Policy attribute to specify a WS-Policy file that contains message-level security policy assertions.</td>
</tr>
<tr>
<td>encryptKeyName (attribute of the security child element)</td>
<td>Use WebLogic-specific @Policy attribute to specify a WS-Policy file that contains message-level security policy assertions.</td>
</tr>
</tbody>
</table>

*Note:* Because this is a WebLogic-specific annotation, you can use it to generate only a JAX-RPC Web service, and not a JAX-WS Web service.

### Table 8–1 (Cont.) Mapping of `servicegen` Attributes to JWS Annotations or `jwsc` Attributes
