Oracle® Fusion Middleware
Creating ADF Skins with Oracle ADF Skin Editor
12c (12.1.2)
E23163-01

June 2013
Documentation for Oracle Application Development Framework (Oracle ADF) developers and user interface designers that describes how to create and apply skins to an application using the ADF Skin Editor.

Welcome to Creating ADF Skins with Oracle ADF Skin Editor.

Audience

This document is intended for application developers and user interface designers who want to change the look and feel of their application by skinning ADF Faces Rich Client components.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

What's New in This Guide

The following topics introduce the new and changed features of the ADF Skin Editor and other significant changes that are described in this guide, and provides pointers to additional information. This book is the new edition of the formerly titled *Skin Editor User’s Guide for Oracle Application Development Framework*.

New and Changed Features for 12c (12.1.2)

The ADF Skin Editor 12c (12.1.2) includes the following new and changed features:

- **Design editor**, this new editor appears when you extend from the Skyros or Fusion Simple families of ADF skin. It can be used to change the most commonly styled parts of applications that use ADF Faces components and also to replace the default images in the ADF skins provided by Oracle ADF. You can preview the changes you make in the sample pages that the editor provides or in a browser that you invoke from the editor. Access the design editor by clicking the Design tab. See Section 3.2, "Working with the ADF Skin Design Editor."

- **Selectors editor**, now displays an interactive preview of the currently-selected component. Clicking the interactive parts of the preview navigates you to the pseudo-element where you configure properties to change the appearance of the component. See Section 3.3.2, "Interactive Preview in the Selectors Editor."

- **Extended Skins**, this list now displays the list of extended skins hierarchically and also displays imported skins. See Section 3.5, "Navigating ADF Skins."

- **Images editor**, now includes the Adjust Hue/Saturation/Brightness dialog that enables you to adjust the hue, saturation and brightness levels of the colors that your ADF skin uses. This editor only appears if your ADF skin extends from the Fusion Simple family of ADF skin. See Section 6.5, "Working with the Images Editor."

- **At-rules**, can now be created and modified using the selectors editor. See Chapter 10, "Working with At-Rules."

- Using Java Management Extensions (JMX), you can deploy ADF skins packaged in an ADF Library JAR to a Fusion web application without having to restart the application. See Section 11.5, "Applying an ADF Skin to a Running Web Application."

- **New ADF skins**, such as *skyros* and *fusionFx-v3*, are described. See Section 12.4, "ADF Skins Provided by Oracle ADF."

- The *fusion* and *fusionFx-simple* ADF skins are deprecated. See Section 12.4, "ADF Skins Provided by Oracle ADF."
Other Significant Changes in this Book

For 12c (12.1.2), this guide has been updated in several ways. Following are the sections that have been added or changed.

- Added section to describe how you can access reference information for ADF skin selectors and CSS properties from within the ADF Skin Editor. See Section 2.4, "Accessing Selector Information from Within the ADF Skin Editor."

- Added section to elaborate on how the ADF skinning framework determines what style property to apply when it overrides the value of a global selector alias from an ADF skin that is extended or within a local ADF skin. See Section 8.4.3, "What You May Need to Know About Applying a Global Selector Alias."

- Revised section to describe how you use an @agent rule to determine styles to apply to agents that are touch devices. See Section 10.2, "Creating an At-Rule."

- Revised section to elaborate on how an application chooses an ADF skin to use if you do not specify values in the trinidad-config.xml or trinidad-skins.xml files. See Section 12.5.2, "What Happens When You Version ADF Skins."

- Removed references to the previously-deprecated Blafplus family of ADF skin throughout the guide.
About Skinning a Web Application

This chapter introduces you to creating an ADF skin with the ADF Skin Editor. It provides an overview of the process of creating an ADF skin, takes a look at some of the changes that an ADF skin can implement, and describes the inheritance relationship of the ADF skins that Oracle ADF provides for you to extend.

This chapter includes the following sections:

- Section 1.1, "Introduction to Skinning a Web Application"
- Section 1.2, "Overview of Developing an ADF Skin"
- Section 1.3, "Taking a Look at an ADF Skin"
- Section 1.4, "Inheritance Relationship of the ADF Skins Provided by Oracle ADF"

1.1 Introduction to Skinning a Web Application

Skinning refers to the task of developing an ADF skin to apply to a web application that uses ADF Faces and ADF Data Visualization components in the user interface. An ADF skin uses the format, properties, and selectors of cascading style sheets (CSS) to allow you to customize the appearance of these components. Instead of providing a CSS file for each component, or inserting a style sheet on each page of the application, you create one ADF skin for the web application. Every component that renders in the user interface automatically uses the styles defined by the ADF skin. This means you do not have to make design-time changes to individual pages to change their appearance when you use an ADF skin.

Using an ADF skin also makes it easy for you to maintain a consistent appearance for all the pages that the application renders. Changes to the appearance of your application can easily be made should you decide to do so. You might decide, for example, to change colors to make your application adhere to your company’s corporate brand. Additionally, you may want to define a style property for a component to make your application more usable. For example, Figure 1–1 shows an ADF Faces inputText component.

Figure 1–1  Writable inputText Component

Enter a value: 

Figure 1–2 shows another ADF Faces inputText component where the background color is grayed out by the ADF skin to indicate to the end user that the inputText component is read only.
Other benefits of skinning include the ability to easily change the default text labels that ADF Faces components render at runtime. For example, the default text for the dialog component’s labels are **OK** and **Cancel** if you set the component’s `type` property to `okCancel`. You cannot modify the values of these labels by specifying properties for the `dialog` component. Instead, if you want to change **OK** to **Submit**, for example, you make changes in the ADF skin that references a resource bundle with the alternative string value. For more information, see Chapter 7, "Working With Text in an ADF Skin."

The previous examples illustrate some of the use cases for ADF skins plus the benefits of creating an ADF skin. Note that you do not have to define all the changes that you want for your application in one ADF skin. You can create different ADF skins to serve different purposes. For example, you might create ADF skins with different color schemes to adhere to the corporate brand of different companies. In addition, you can configure an application so that end users can dynamically change the ADF skin at runtime.

Note that this guide makes the following assumptions:

- You are familiar with the ADF Faces and ADF Data Visualization components that you can skin. The usage and functionality of these components is beyond the scope of this guide. For more information about these components, see *Developing Web User Interfaces with Oracle ADF Faces* (for the release that pertains to the application you are skinning).

- You are familiar with CSS. It is beyond the scope of this guide to explain CSS. For extensive information about CSS, including the official specification, visit the World Wide Web Consortium (W3C) web site at:

  http://www.w3.org/

### 1.2 Overview of Developing an ADF Skin

Developing an ADF skin is an iterative process. Before you proceed, familiarize yourself with the concepts of CSS plus the ADF Faces and ADF Data Visualization components. The high level steps to develop an ADF skin are:

1. Create a source file for the ADF skin.

   You create a source file where you write the declarations for the selectors that the ADF skinning framework exposes. When creating a source file using the editor in JDeveloper or the ADF Skin Editor, you must choose an existing ADF skin to extend from. If this ADF skin is the first ADF skin that you create, you choose from one of the ADF skins that Oracle ADF provides. For more information, see Section 12.4, "ADF Skins Provided by Oracle ADF." For information about the inheritance relationship between these ADF skins, see Section 1.4, "Inheritance Relationship of the ADF Skins Provided by Oracle ADF." If you create subsequent ADF skins, you can choose to extend from an ADF skin that you created previously.

   For more information about creating an ADF skin, see Section 4.3, "Creating an ADF Skin File."

2. Write declarations for the selectors, rules, and pseudo-elements in the ADF skin that you created.
The ADF Skin Editor provides a number of tabs that facilitate this task. Choose the appropriate tab. For example, the Design tab (if available) provides you with controls in a design editor where you can quickly change the most commonly styled parts of applications that use ADF Faces components. A number of sample pages in the lower part of the tab refresh to display the changes you make using the provided controls. In contrast, use the Selectors tab for more advanced changes as this latter tab displays a selectors editor for all the selectors exposed by the ADF skinning framework in a Selector Tree and provides a Properties window and a number of other controls where you can modify these selectors.

The design editor appears if you extend your ADF skin from the Skyros and Fusion Simple families of ADF skin. The selectors editor appears irrespective of the skin family that you extend from. For more information, see Section 3.2, "Working with the ADF Skin Design Editor" and Section 3.3, "Working with the ADF Skin Selectors Editor."

For a description of the different categories of selectors, rules, and pseudo-elements, see Chapter 2, "Working with ADF Skin Selectors."

3. If applicable, import images that you want your ADF skin to reference at runtime in the Fusion web application. For more information, see Chapter 6, "Working with Images and Color in Your ADF Skin."

   **Tip:** The design editor described in Step 2 provides controls that enable you to export and import all images that the ADF skin references. Once exported, you can edit the images using your preferred software program before you import them back into your ADF skin project. The same tab also provides controls to replace individual images. Finally, an Images tab appears if your ADF skin extends from the Fusion Simple family. This tab provides controls to edit images in your ADF skin. For more information about the images editor, see Section 6.5, "Working with the Images Editor."

4. If applicable, override the default text labels defined for the ADF Faces and ADF Data Visualization components by entering new values in a resource bundle. For more information, see Chapter 7, "Working With Text in an ADF Skin."

5. If applicable, edit or create themes in your ADF skin. Themes are a way of implementing a look and feel at a component level. For more information, see Section 5.6, "Applying Themes to ADF Faces Components."

6. Preview and test the changes that you made to the ADF skin to verify that the results are what you want. Modify the ADF skin as necessary. The design editor described in Step 2 provides a number of sample pages where you can view your changes within the ADF Skin Editor or within a browser by clicking the **Preview in Browser** icon, as described in Section 3.2, "Working with the ADF Skin Design Editor." For information about previewing and testing an ADF skin in a running Fusion web application, see Section 11.2, "Testing Changes in Your ADF Skin."

7. Once you complete development of the ADF skin, you may want to package it for distribution. For more information, see Section 11.3, "Packaging an ADF Skin into an ADF Library JAR."

8. Having completed the ADF skin and distributed it, you configure your Fusion web application so that it uses it. For more information, see Section 11.4, "Applying an ADF Skin to Your Web Application."
1.3 Taking a Look at an ADF Skin

An ADF skin is a type of cascading style sheet. It differs from a cascading style sheet in a number of ways. One way it differs is that you can specify properties for the selectors that the ADF skinning framework exposes in the source file for the ADF skin. A selector exposed by the ADF skinning framework is similar to a CSS selector in that it identifies the ADF Faces and ADF Data Visualization components for which you want to change the appearance and allows you to specify one or more style properties for the component.

A selector exposed by the ADF skinning framework differs from a CSS selector in that it allows you to set values both for CSS properties and ADF skin properties exposed by the ADF skinning framework. CSS properties are interpreted directly by the end user’s browser. ADF skin properties are prefaced by the characters -tr-. Some of these ADF skin properties are read and interpreted by the Fusion web application. These properties are also known as server-side properties. A component that renders in the user interface may read these properties before it decides what to render. Other types of ADF skin properties, for example -tr-rule-ref or -tr-property-ref, enhance the capabilities of the ADF skinning framework, as described in Section 2.3, "Properties in the ADF Skinning Framework."

Example 1–1 shows the selector for the gauge component that sets values for the ADF skin properties -tr-graphic-antialiasing and -tr-animation-indicators, plus the CSS properties background-color and font-family.

Example 1–1  Gauge Component's Selector with ADF Skin and CSS Properties

```css
af|dvt-gauge
{
  /** ADF skin properties */
  -tr-graphic-antialiasing: false;
  -tr-animation-indicators: none;
  /** CSS properties */
  font-family: Geneva, Arial, Helvetica, sans-serif;
  background-color: rgb(243,255,185);
}
```

As Example 1–1 demonstrates, you can set values for CSS properties and ADF skin properties within the declaration of a selector exposed by the ADF skinning framework. The ADF skinning framework exposes the ADF skin properties that you can define. In addition to ADF skin properties, the ADF skinning framework defines a number of pseudo classes and at-rules that you can specify in an ADF skin. Examples of supported at-rules and pseudo classes include @platform, @agent, @accessibility-profile, :rtl, and @locale. For more information, see Chapter 2, "Working with ADF Skin Selectors."

At runtime, the Fusion web application creates a browser-specific CSS file from the ADF skin. The application then references this browser-specific CSS file as it would any CSS file.

Figure 1–3 demonstrates the impact that an ADF skin can have on the appearance of an application's page. The page on the left renders using the skyros ADF skin. The page on the right renders using the simple ADF skin. Each ADF skin defines values for colors and fonts. The skyros ADF skin uses many more colors, in addition to referencing an image for the Oracle logo.
Oracle ADF provides a number of ADF skin families that you can use in your application or extend when you create an ADF skin. The ADF skins provided by Oracle ADF offer increasing levels of customization for the appearance rendered by ADF Faces and ADF Data Visualization components at runtime. Figure 1–4 illustrates the inheritance relationship between the different ADF skin families where, for example, the fusion-base ADF skin inherits the style properties defined in the simple ADF skin in addition to defining more style properties. All ADF Faces components use, at a minimum, styles defined in the simple ADF skin as this is the skin from which the others extend from. The simple ADF skin defines the minimum style properties that ADF Faces components require to render in an ADF application. If you want to create an ADF skin with a minimal amount of customization, you create an ADF skin that extends from the simple ADF skin. If you want an ADF skin with more customization than the simple ADF skin but one that is easier to modify relative to other ADF skin families, consider extending from the Skyros or Fusion Simple families. A design editor is available to you when you extend from these ADF skin families. This editor provides controls (for example, color pickers) to change your ADF skin and sample pages where you can view immediately view the effect of the changes you make.

Note: An ADF skin can affect the time it takes a client to render the user interface. The more styles that an ADF skin uses, the more the client has to load. This can affect performance in low bandwidth or high latency environments.
You can apply any of the ADF skins in Figure 1–4 (except for the fusion and fusion-simple skins) or an ADF skin that you create yourself to an application. For more information about applying an ADF skin to an application, see Section 11.4, “Applying an ADF Skin to Your Web Application.” The fusion and fusion-simple skins are deprecated.

For a more detailed description of the ADF skins that Oracle ADF provides, see Section 12.4, “ADF Skins Provided by Oracle ADF.”
This chapter describes the ADF skin selectors. These selectors along with pseudo-elements, pseudo-classes, ADF skin properties and ADF skinning framework rules allow you to customize the appearance of ADF Faces and ADF Data Visualization components.

This chapter includes the following sections:

- **Section 2.1, "About ADF Skin Selectors"**
- **Section 2.2, "Pseudo-Classes in the ADF Skinning Framework"**
- **Section 2.3, "Properties in the ADF Skinning Framework"**
- **Section 2.4, "Accessing Selector Information from Within the ADF Skin Editor"**

### 2.1 About ADF Skin Selectors

The ADF skinning framework provides a range of selectors that you can specify in an ADF skin to customize the appearance of ADF Faces and ADF Data Visualization components. There are two types of selectors: global selectors and component-specific selectors. A global selector defines style properties that you apply to one or more selectors. A component-specific selector defines style properties that apply to one component.

The ADF skins provided by Oracle ADF define many global selectors (Global Selector Aliases in the user interface of the selectors editor) that many ADF Faces components inherit. For example, many ADF Faces components use the .AFDefaultFontFamily:alias selector to specify the font family. If you create an ADF skin that overrides this selector by specifying a different font family, that change affects all the components that have included the .AFDefaultFontFamily:alias selector in their selector definition. Figure 2-1 shows the .AFDefaultFontFamily:alias selector in the source view and the design view. The View as list displays the current list of ADF Faces components that use the value defined in the .AFDefaultFontFamily:alias global selector alias to determine what font family to use.
An ADF skin that you create inherits the global selector aliases defined in the ADF skin that it extends from. You can also create new global selector aliases in your ADF skin files. For more information, see Chapter 8, “Working With Global Selector Aliases.”

Component-specific selectors are selectors that the ADF skinning framework exposes that allow you to identify the corresponding ADF Faces and ADF Data Visualization components for which you can define style properties. For example, Figure 2–2 shows the selector for the ADF Faces button component in the source editor and selectors editor. The value of the property that determines the color of the font to appear in the button has been changed to Red in the Properties window.
For more information about the component-specific selectors, see Chapter 5, "Working with Component-Specific Selectors." For more information about global selector aliases, see Chapter 8, "Working With Global Selector Aliases."

### 2.1.1 ADF Skin Selectors and Pseudo-Elements

Many ADF skin selectors expose pseudo-elements. A pseudo-element denotes a specific area of a component for which you can define style properties. Pseudo-elements are denoted by a double colon followed by the portion of the component the selector represents. For example, Figure 2–3 shows how the `week-header-row` pseudo-element exposed by the `af|chooseDate` selector allows you to configure style properties for the appearance of the calendar grid.
2.1.2 ADF Skin Selectors and Icon Images

ADF Faces components that render icons do so using a set of base icon images. No CSS code entries appear in the source file of the ADF skin for these icon images in contrast to, for example, the CSS code entries that appear in a source file when you specify an image as a value for the CSS `background-image` property. Instead, the ADF skinning framework registers the icon image for use with the renderer. For more information about the renderer and supported render kits, see Section 12.2, "ADF Skinning Framework and Supported Render Kits."

ADF skin selectors use two naming conventions for pseudo-elements that identify icon images that render in a component. The names of these pseudo-elements end in `-icon` or in `-icon-style`. Figure 2–4 shows the example of the Panel Accordion selector’s pseudo-elements. Pseudo-elements that end in `-icon-style` specify a background image, as shown in Figure 2–4. In contrast, pseudo-elements that end in `-icon` do not specify a background image, but can reference IMG elements or text, as in the following examples:

```html
af|panelAccordion::undisclosed-icon {content "X"}
af|panelAccordion::undisclosed-icon {content: url("http://server:port/img/img.png")}
```
In Figure 2–4, the undisclosed-icon-style pseudo-element styles the icon used for the undisclosed icon in the panelAccordion component. This pseudo-element specifies the icon as a background image. Use the :hover and :active pseudo-classes to customize the appearance. For example, write the following syntax to make the background red if the end user hovers the mouse over the icon:

```
af|panelAccordion::undisclosed-icon-style:hover {
    background-color: Red;
}
```

**Tip:** Many browsers do not render background images when in accessibility mode. The following example demonstrates how you can work around this behavior if you want your application to display an image when in accessibility mode.

If you want to use your own image rather than the icon specified as a background image, you need to first prevent the background image from rendering. Do this by specifying the -tr-inhibit ADF skin property for the component's selector pseudo-element as follows:

```
af|panelAccordion::undisclosed-icon-style
{
    -tr-inhibit: background-image;
}
```

Next you specify the text or image that you want to render as a value for the content property of the undisclosed-icon selector. For example, write syntax similar to the following to specify an alternative image:

```
af|panelAccordion::undisclosed-icon
{
    content:url('images/undisclosed.png');
    width: 10px;
    height: 10px;
}
```

The ADF skinning framework also defines a number of global selector aliases that specify icon images to use in different scenarios. These global selector aliases appear under the Icons node in the Selector Tree of the selectors editor, as shown in Figure 2–5. The .AFChangedIcon:alias shown in Figure 2–5 enables you to globally set the changed icon for all components using that icon.
These icons can also be viewed and changed using the Replace Icons dialog that you invoke from the design editor, as described in Section 6.2, "Changing Images and Colors in the ADF Skin Design Editor," if your ADF skin extends from the Skyros or Fusion Simple families of ADF skin. Figure 2–6 shows the dialog that appears for an ADF skin that extends from the Skyros family of ADF skins.

For more information, see Chapter 6, "Working with Images and Color in Your ADF Skin."

2.1.3 Grouped ADF Skin Selectors

You can group ADF skin selectors and global selector aliases to minimize the number of entries in the source file of the ADF skin. The selectors that you group render under the Grouped Selectors node in the Selector Tree, as shown in Figure 2–7. The View as list in the Preview Pane displays all the selectors that you grouped.

As the selectors editor does not provide a way to specify grouped selectors, you use the source editor to specify the selectors and/or global selector aliases that you want to put in a grouped selector. Separate each selector by a comma (,) to include in the grouped selector.
2.1.4 Descendant ADF Skin Selectors

A descendant selector is made up of two or more selectors separated by white space. You can configure descendant selectors for ADF skin selectors. These allows you to configure style properties for specific selectors when they render within another selector. When you configure a descendant selector, the selectors editor displays a Descendant Selectors node under the selector included in the descendant selector, as shown in Figure 2–8.
As the selectors editor does not provide a way to specify descendant selectors, you use the source editor to specify the selectors and/or global selector aliases that you want to specify in a descendant selector. Separate each selector by a white space.

### 2.2 Pseudo-Classes in the ADF Skinning Framework

The CSS specification defines pseudo-classes, such as `:hover` and `:active`, which are used to define style properties for when a selector is in a particular state. You can apply these pseudo-classes to almost every ADF Faces component. In addition, the ADF skinning framework provides additional pseudo-classes for specialized functions. Examples include pseudo-classes to apply when a browser’s locale is a right-left language (`:rtl`) or for drag and drop operations (`:drag-target` and `:drag-source`). The syntax that appears in the source file of an ADF skin to denote a pseudo-class uses the following format(s):

```
adfskinselector:pseudo-class
adfskinselector::pseudo-element:pseudo-class
```

Figure 2-9 shows the syntax that you write in the source file of an ADF skin for the `:hover` pseudo-class so that a `panelList` component’s link renders orange when the end user hovers a cursor over the link in Figure 2-9.
Some components make more use of pseudo-classes than other components. The `panelBox` component’s selector, for example, makes extensive use of pseudo-classes to define its appearance when it is in various states (for example, active, disabled, or busy). Figure 2–10 shows the list of available pseudo-classes that renders when you select the `panelBox` component’s selector in the Selector Tree and click the Add Pseudo-Class icon to display the list of available pseudo-classes in an ADF skin that extends from the Skyros family of ADF skins.
Pseudo-classes can also be applied to pseudo-elements that selectors expose. The `panelBox` component selector’s pseudo elements are a good example. Figure 2–11 shows the list of pseudo-classes that the `center` pseudo-element exposed by the `panelBox` component selector accepts. Many of these pseudo-classes allow you to define the appearance for the `panelBox` component depending on the value that the application developer sets for its attributes. For example, the `core` and `highlight` pseudo-classes define the corresponding appearance when the application developer sets the `panelBox` component’s `ramp` attribute to `core` or `highlight`.

The following are common pseudo-classes used by ADF Faces selectors.

- **Drag and drop**: The two pseudo-classes available are `:drag-source` applied to the component initiating the drag and removed once the drag is over, and...
Properties in the ADF Skinning Framework

:drop-target applied to a component willing to accept the drop of the current drag.

- **Standard:** In CSS, pseudo-classes like :hover, :active, and :focus are considered states of the component. This same concept is used in applying skins to components. Components can have states like read-only or disabled. When states are combined in the same selector, the selector applies only when all states are satisfied.

- **Right-to-left:** Use this pseudo-class to set a style or icon definition when the browser is in a right-to-left language. Another typical use case is asymmetrical images. You will want the image to be flipped when setting skin selectors that use the image in a right-to-left reading direction. Be sure to append the :rtl pseudo-class to the very end of the selector and point it to a flipped image file. The skin editor's preview pane does not render changes that you make to a flipped image file. The following example from the Skyros skin shows the image that the calendar component's toolbar-day-hover-icon pseudo-element references when it renders in a browser that uses a right-to-left language:

  ```css
  af|calendar::toolbar-day-hover-icon:rtl {
    content: url(/afr/cal_day_ovr_rtl.png);
    width: 16px;
    height: 16px;
  }
  ```

  You can also use :rtl to apply to skin icons. For more information, see Chapter 6, "Working with Images and Color in Your ADF Skin."

- **Inline editing:** This pseudo-class is applied when the application activates a component subtree for editing in the browser. For example, :inline-selected is a pseudo-class applied to currently selected components in the active inline-editable subtree.

- **Message:** This pseudo-class is used to set component-level message styles using CSS pseudo-classes of :fatal, :error, :warning, :confirmation, and :info. For more information, see Section 5.5, "Configuring ADF Skin Properties to Apply to Messages."

  **Note:** The global selector aliases that appear in the Selector Tree are a special type of pseudo-class (:alias). For more information, see Chapter 8, "Working With Global Selector Aliases."

2.3 Properties in the ADF Skinning Framework

The ADF skinning framework defines a number of ADF skin properties. The Fusion web application, rather than the user's browser, interprets ADF skin properties. When configured, ADF skin properties enable you to do the following:

- **Reference styles from other selectors with the -tr-rule-ref property.**

  Create your own global selector alias and combine it with other selectors using the -tr-rule-ref property. For more information, see Section 8.2, "Creating a Global Selector Alias," Section 8.3, "Modifying a Global Selector Alias," and Section 8.4, "Applying a Global Selector Alias."

- **Suppress styles defined in an ADF skin with the -tr-inhibit skin property.**

  Suppress or reset CSS properties inherited from a base skin with the -tr-inhibit skin property. For example, the -tr-inhibit:padding property
removes any inherited padding. Remove (clear) all inherited properties with the
-tr-inhibit:all property. The suppressed property name must be matched
exactly with the property name in the base skin.

- Reference the value of a property defined in another selector using the
  -tr-property-ref property.
  
  For more information, see Section 8.5, "Referencing a Property Value from Another
  Selector."

- Configure the themes for child components with the -tr-children-theme
  property.
  
  For more information, see Section 5.6, "Applying Themes to ADF Faces
  Components."

- ADF skin selectors with style properties.
  
  Skin style properties allow you to customize the rendering of a component
  throughout the application. A CSS property is stored with a value in the Skin
  object and is available when the component is being rendered. For example, in
  af|breadCrumbs{-tr-show-last-item: false}
  
  the skin property
  -tr-show-last-item is set to hide the last item in the breadCrumbs
  component's navigation path.

  The ADF skinning framework also provides the + and - operators that allow you to
  set a selector's color or font properties relative to the value that you specify for the
  color or font properties of another selector. This is useful if you want to apply a range
  of colors to selectors or maintain a relative size between fonts.

  Example 2–1 demonstrates the syntax that you write to make use of this feature for a
  color property. A global selector alias defines the background color that two additional
  global selector aliases (.fooColorTestPlus and .fooColorTestMinus) apply
  using the + and - operators.

  Example 2–1 Using the + and - Operators to Apply Color

  .BaseBackgroundColor:alias { background-color: #0099ff; }
  .fooColorTestPlus {
    -tr-rule-ref: selector(".BaseBackgroundColor:alias");
    background-color: +#333333;
  }
  .fooColorTestMinus {
    -tr-rule-ref: selector(".BaseBackgroundColor:alias");
    background-color: -#333333;
  }

  Example 2–2 demonstrates the syntax that you write to make use of this feature for a
  font property. A global selector alias defines the font size and an additional global
  selector alias (.fooFontTest) increases this font size by 1pt using the + operator.

  Example 2–2 Using the + Operator to Increase Font Size

  .FontSizeTest:alias {font-size: 12pt;}
  .fooFontTest {
    -tr-rule-ref: selector(".FontSizeTest:alias");
    font-size:+1pt;
  }
2.4 Accessing Selector Information from Within the ADF Skin Editor

You can access reference information for the ADF skin selectors and CSS properties that you configure in your ADF skin in a number of ways within the ADF Skin Editor. The reference information that you can access includes the following reference documents for ADF skin selectors:

- **Tag Reference for Oracle ADF Faces Skin Selectors**
- **Oracle Fusion Middleware Data Visualization Tools Tag Reference for Oracle ADF Skin Selectors**

(for the release that pertains to the application you are skinning)

You can access these reference documents in the Oracle ADF Skin Editor Documentation Library or in a Help Center window if you click the link in the information text that appears when you hover over a selector in the Selector Tree, as shown in Figure 2–12.

![Figure 2–12 Reference Documentation for ADF Skin Selectors](image)

In addition to referencing information for the ADF skin selectors, you can access information for CSS selectors. You do this from the Source tab of the editor by selecting the CSS property and pressing Control + D or choosing **Show Quick Reference**, as illustrated in Figure 2–13.

![Figure 2–13 Quick Reference Documentation for CSS Properties](image)
This chapter describes the editors that the ADF Skin Editor provides to create ADF skins. Key features of these editors, such as the Selector Tree that you use to browse the selectors that you can configure in an ADF skin, the Properties window that you use to set properties, and how you navigate to an ADF skin that you extend, are also described.

This chapter includes the following sections:
- Section 3.1, "About the ADF Skin Editor"
- Section 3.2, "Working with the ADF Skin Design Editor"
- Section 3.3, "Working with the ADF Skin Selectors Editor"
- Section 3.4, "Working with the Properties Window"
- Section 3.5, "Navigating ADF Skins"
- Section 3.6, "Customizing the ADF Skin Editor"
- Section 3.7, "Searching the Source Files of ADF Skins"
- Section 3.8, "Working with Extensions"
- Section 3.9, "Adding External Tools to the ADF Skin Editor"
- Section 3.10, "Navigating the ADF Skin Editor"
- Section 3.11, "Working with the Resources Window"

### 3.1 About the ADF Skin Editor

The ADF Skin Editor is a tool that creates ADF skins for applications built using various releases of Oracle ADF. It provides a number of visual and source editors where you edit the selectors exposed by the ADF Faces framework, preview your changes, and package the final ADF skin into an ADF Library JAR.

Key features of the ADF Skin Editor include the:
- ADF Skin Design Editor (design editor) where you can declaratively modify an ADF skin that extends from the Skyros or Fusion Simple families of ADF skin using the provided controls.
- ADF Skin Selector Editor (selectors editor) where you can view all of the selectors exposed by the ADF Faces framework in the Selector Tree.
- Properties window where you can modify the properties of the selectors that you choose in the Selector Tree.
3.2 Working with the ADF Skin Design Editor

By default, the design editor opens when you create an ADF skin that extends from the Skyros or Fusion Simple families of ADF skin, as described in Section 4.3, "Creating an ADF Skin File." This editor provides a variety of controls to change the most commonly styled parts of applications.

The lower part of the design editor displays a number of sample pages that render a wide variety of the commonly used ADF Faces components, such as buttons, links, and panel accordions. These sample pages refresh to reflect the changes that you make using the various controls in the upper part of the editor. A Preview in Browser icon renders the sample page in a browser when clicked. In Figure 3–1, for example, clicking this icon renders the sample page in Internet Explorer. You can choose to render the sample page in another browser, as described in Section 3.2.1, "How to Change the Browser that Renders the Design Editor's Sample Pages."

The upper part of the design editor displays a variety of tabs that group together controls to modify the selectors for various areas of an application page, such as the branding area, the global area, buttons, links, and menus. Within each tab, user interface controls such as color pickers, input text components and links to invoke dialogs appear. Figure 3–1 shows the General tab in the design editor that appears when you extend an ADF skin from the Skyros ADF skin. This tab renders color pickers that you can invoke when you click the dropdown arrows beside the fields that display the current color values, dropdown lists where you can select different fonts and font size and links to invoke dialogs where you can replace the images that the ADF skin references for status icons, animations and components.

Figure 3–1  ADF Skin Design Editor

Any changes that you make using the controls in the design editor result in the generation of CSS syntax that appears in the source file of the ADF skin. The design editor is useful for changing the commonly styled parts of an application. For example, one click in the Branding Area tab invokes a dialog where you can select a new image to render as the logo in the branding area of your application's page. Consider using the selectors editor, described in Section 3.3, "Working with the ADF
Skin Selectors Editor,” when you need to go beyond changing the most commonly styled parts.

For more information about how you can use the design editor to change colors and images, see Section 6.2, “Changing Images and Colors in the ADF Skin Design Editor.”

3.2.1 How to Change the Browser that Renders the Design Editor’s Sample Pages

You can change the browser that renders the design editor’s sample pages when you click the Preview in Browser icon.

To change the browser that renders the design editor’s sample pages:
1. From the main menu, choose Tools > Preferences.
2. In the Preferences dialog, select the Web Browser and Proxy page.
3. Choose the browser that you want to use in the Web Browsers list.
4. Click OK.

3.3 Working with the ADF Skin Selectors Editor

Figure 3–2 shows the selectors editor. Each label number corresponds to a description in the list that follows Figure 3–2. The selectors editor opens by default if the ADF skin that you create extends from a skin family that is not Skyros or Fusion Simple. If your ADF skin extends one of these two skin families, you can access the selectors editor by clicking the Selectors tab.
1. The Projects node in the Applications window displays the source files for the ADF skins that you create. It also displays associated configuration and image files. By default, the ADF Skin Editor saves an ADF skin to a directory named skins. You can specify an alternative directory name to store the source files. For more information about creating ADF skins, see Chapter 4, "Creating the Source Files for an ADF Skin."

2. The Structure window lists the selectors, global selector aliases, style classes, and at-rules that you added to the ADF skin file.

3. Click the Hide/Show Divider icon to hide or show the Selector Tree.

4. Filter the selectors that appear in the Selector Tree.

   You can enter text in the input text field to filter the list of selectors that appear in the Selector Tree or you can use the filter icon to display:

   - **Available Selectors**: all selectors in the Selector Tree.
   - **Updated Selectors**: only those selectors that you modified in the ADF skin.
   - **Selectors with At-Rules**: only those selectors that have an associated at-rule.

5. The Extended Skins list displays the list of ADF skins from which the current ADF skin extends. It also identifies imported ADF skins.

   For more information, see Section 3.5, "Navigating ADF Skins."
6. Use the **Add** icon to create a new style class, alias selector, or at-rule.

   For information about creating a new style class, see Chapter 9, "Working with Style Classes." For information about creating an alias selector, see Chapter 8, "Working With Global Selector Aliases." For information about creating an at-rule, see Chapter 10, "Working with At-Rules."

7. Use the **Delete** icon to remove a selector that you added to the ADF skin.

8. Click the **Refresh** icon to update the Preview Pane after you make changes to the properties of a selector in the Properties window.

9. Click the **Add Pseudo-Class** icon to apply a pseudo-class to the item that you selected in the Selector Tree.

   For more information about pseudo-classes, see Section 2.2, "Pseudo-Classes in the ADF Skinning Framework."

10. Click the **Clear Property Settings** icon to undo any change that you made to the item selected in the Selector Tree.

11. Click the **Delete Pseudo-Class from Skin File** icon to delete any pseudo-classes that you specified in the ADF Skin.

12. The **View as** list allows you to preview how changes you make to a global selector alias in the Selector Tree affect the components that reference the global selector alias. The **View as** list displays all components that reference the global selector alias. The **View as** list also allows you to preview how changes you make to the properties of one component-specific selector impact all sub-types of that component. For example, Figure 3–3 shows the ADF Data Visualization component selector for the `graph` component (af|dvt-graph) that exposes a single set of component-specific selectors that apply changes to all graph types.

   Use the **View as** list to preview a change that you make to a selector in one of the other types of graph (for example, Bar, Funnel, Pareto, and so on).

   **Figure 3–3 View as List for a Component**

   ![View as List for a Component](image)

   For more information about global selector aliases, Chapter 8, "Working With Global Selector Aliases."
13. The Selector Tree displays the list of selectors, global selector aliases, style classes, and at-rules that you can configure values for in an ADF skin.

   For more information, see Section 3.3, "Working with the ADF Skin Selectors Editor."

14. The Preview Pane renders a preview of the changes that you make to a selector in an ADF skin after you click the Refresh icon (8).

15. You can also view the source of an ADF skin file.

   Tip: Select Split Document from a context menu that you can invoke from the Preview Pane to render the source and design views of an ADF skin side by side.

16. The Properties window identifies properties that you can configure for the ADF skin.

   For more information, see Section 3.4, "Working with the Properties Window."

17. The tabs for themes allow you to preview changes that you make for supported themes.

   For more information, see Section 5.6, "Applying Themes to ADF Faces Components."

18. The images editor helps you manage the images that you want to use with an ADF skin. This tab appears if the ADF skin you create extends from the Fusion Simple family of ADF skin.

   For more information, see Section 6.5, "Working with the Images Editor."

### 3.3.1 About the Selector Tree

The Selector Tree displays a list of the style classes, global selector aliases, and selectors for which you can configure properties to change the appearance of ADF Faces and ADF Data Visualization components.

Figure 3–4 shows the nodes that the Selector Tree exposes:

- **Style Classes**
  A style class defines one or more style properties that you can apply to specific instances of a component. The selectors editor categorizes the inherited style classes into style classes defined for general usage, note windows, and popups.
  For more information, see Chapter 9, "Working with Style Classes."

- **Global Selector Aliases**
  A global selector alias defines style properties that you apply to one or more selectors. The selectors editor categorizes the inherited global selector aliases into selector aliases defined for general usage, icons, and messages.
  For more information, see Chapter 8, "Working With Global Selector Aliases."

- **Grouped Selectors**
  Identifies style properties grouped into one declaration to apply to more than one selector. For example, Figure 3–4 shows a grouped selector for the button and link component’s selectors.

- **At-Rules**
At-rules are a way to define style properties for when an application’s page renders in a particular environment such as, for example, when using a specific browser. For more information, see Chapter 10, "Working with At-Rules."

- Faces Component Selector
  Selectors identify the ADF Faces components for which you can configure properties. The selectors editor displays subcategories for pseudo-elements, component selector aliases, and descendant selectors. For brevity, the ADF Faces components node is not expanded. For more information, see Chapter 5, "Working with Component-Specific Selectors."

- Data Visualizations Component Selectors
  Selectors identify the ADF Data Visualization components for which you can configure properties. The selectors editor displays subcategories for pseudo-elements, component selector aliases, and descendant selectors. For more information, see Chapter 5, "Working with Component-Specific Selectors."

**Figure 3–4 Selector Tree**

3.3.2 Interactive Preview in the Selectors Editor

The preview pane in the selectors editor displays an interactive preview of the component that is currently selected in the Selector Tree. Hover your mouse over this preview to view text that identifies the specific pseudo-element that you need to customize to change the appearance of the component. Clicking on parts of this preview navigates you to the location where you can configure properties to change the appearance of what you have just clicked on. You can also right-click a pseudo-element to invoke a context menu that displays a hierarchical list of the selector pseudo-elements that the current pseudo-element contains, as shown in Figure 3–5.
Clicking an entry in the context menu that appears or clicking a part of the calendar component that uses properties defined in the pseudo-element of another component selector navigates you to that pseudo-element in the Selector Tree. For example, if you click `af|button::link` in the context menu in Figure 3–5, the component preview navigates you to the location for the `button` component selector’s pseudo-element in the Selector Tree, as shown in Figure 3–6.

### Figure 3–6 Button Component’s link Pseudo-Element

#### 3.4 Working with the Properties Window

The Properties window serves a number of functions apart from its primary role of allowing you to set values for CSS properties and ADF skin properties for the selectors that the ADF skinning framework exposes. These functions are the ability to:

- Copy an image into the project where you develop the ADF skin.
For more information, see Chapter 6, "Working with Images and Color in Your ADF Skin."

- Identify the properties that inherit their values from an extended ADF (blue icon) skin and identify the properties that you configured (green icon) in the ADF skin, as shown in Figure 3–7.

- Identify the properties that are associated with at-rules, as shown in Figure 3–7. For more information about at-rules, see Chapter 10, "Working with At-Rules."

- Present ADF skin properties that you can configure for a selector. For more information, see Section 2.3, "Properties in the ADF Skinning Framework."

- Navigate to the selector in an extended ADF skin that defines an inherited property in your ADF skin (Go to Declaration). For more information, see Section 3.5, "Navigating ADF Skins."

- Invoke a dialog where you can define the colors for properties that support color value.

Figure 3–7 presents an overview of the various controls that the Properties window exposes when you edit an ADF skin.

**Figure 3–7 Controls in the Properties Window for ADF Skins**

- Blue icon indicates this property inherits its value.
- Icon indicates this property is associated with an at-rule.
- Green icon indicates the property has been modified.
- Properties prefixed by `t-c-` are ADF skin properties, not CSS properties.

Hover your mouse over the icons that indicate a property associated with an at-rule or a property that inherits its value in order to display an information tip, as shown in Figure 3–8. Clicking the hyperlink in this information tip navigates you to the source file of the ADF skin where the at-rule or inherited property value is defined.
3.5 Navigating ADF Skins

When you create an ADF skin, as described in Section 4.3, ”Creating an ADF Skin File,” you choose an ADF skin from which to extend. The ADF skin that you choose to extend from defines properties that your newly created ADF skin inherits. When you create your first ADF skin, you must choose one of the ADF skins that Oracle ADF provides.

Subsequent ADF skins that you create can extend an ADF skin that you created or one of the ADF skins provided by Oracle ADF. For example, you create your first ADF skin named skinA that extends the simple ADF skin provided by Oracle ADF. You then create a second ADF skin named skinB. When creating skinB, you have the choice of extending from skinA or from any of the ADF skins provided by Oracle ADF. If you choose to extend skinB from skinA, the inheritance relationship between the ADF skins is illustrated in Figure 3–9.

For more information about the ADF skins that Oracle ADF provides, see Section 1.4, ”Inheritance Relationship of the ADF Skins Provided by Oracle ADF,” and Section 12.4, ”ADF Skins Provided by Oracle ADF.”

The Extended Skins list in the selectors editor displays the list of ADF skins that the current ADF skin extends. The list also identifies if any of the ADF skins that your skin extends include imported skins. Figure 3–10 shows the list of ADF skins that appears if you implement the inheritance relationship described in Figure 3–9. You open an extended ADF skin that you want to view by clicking it in the Extended Skins list.
Navigating ADF Skins

Using the **Go to Declaration** menu that the Properties window exposes, you can navigate to the location in an extended ADF skin where the extended ADF skin declares style properties inherited by other ADF skins. For example, assume that the `skinA` ADF skin defines a background color of Red for the `af|button` selector’s `access-key` pseudo-element, as shown in Figure 3.5.

**Figure 3–11 Declaration of a Property Value**

The `skinB` ADF skin that extends from `skinA` ADF skin inherits the property values, as shown in Figure 3.5.

**Figure 3–12 Inheriting a Property Value from an Extended Skin**

To go to the declaration of a property:

1. Identify a property in your ADF skin that inherits its values from an extended ADF skin. A blue upward-pointing arrow, as shown in Figure 3–12, identifies these properties.

2. Click the icon that appears when you hover over the property field to invoke a context menu where you select **Go to Declaration**, as shown in Figure 3–13.

**Note:** You cannot edit the properties of the selectors in the ADF skins provided by Oracle ADF. You can only edit the properties of selectors in extended ADF skins that you created.
3.6 Customizing the ADF Skin Editor

You can alter the appearance and functionality of a variety of ADF Skin Editor features.

3.6.1 How to Change the Look and Feel of the ADF Skin Editor

You can alter the appearance of the ADF Skin Editor using pre-defined settings.

**To change the look and feel of the ADF Skin Editor:**

1. From the main menu, choose Tools > Preferences. For more information at any time, press F1 or click Help from within the Preferences dialog.
2. In the Preferences dialog, select the Environment node if it is not already selected.
3. On the Environment page, select a different look and feel from the Look and Feel list.
4. Click OK.
5. Restart the ADF Skin Editor.

**Note:** The key bindings in Motif are different from key bindings in Windows. Under Motif, the arrow keys do not change the selection. Instead they change the lead focus cell. You must press Ctrl + Space to select an item. This is expected behavior.
3.6.2 How to Customize the General Environment for the ADF Skin Editor

You can customize the default display options (for example, always display dockable windows on top), as well as other general behavior, such as whether the ADF Skin Editor will automatically reload externally modified files and whether output to the Log window is automatically saved to a file.

To change the general environment settings for the ADF Skin Editor:

1. From the main menu, choose **Tools > Preferences**. For more information at any time, press F1 or click **Help** from within the Preferences dialog.
2. In the Preferences dialog, select the **Environment** node if it is not already selected.
3. On the Environment page, select the options and set the fields as appropriate.
4. Click **OK**.
5. Restart the ADF Skin Editor.

For information about how to start the ADF Skin Editor, see *Installing Oracle ADF Skin Editor* (for the release that pertains to the application you are skinning).

3.7 Searching the Source Files of ADF Skins

The ADF Skin Editor provides a source editor where you can view, edit, and search the syntax that the design and selectors editors generate for an ADF skin.

3.7.1 How to Search the Source Files of ADF Skins

You can search the source files of an ADF skin in a number of ways.

**To search a source file currently open in the source editor, with the option to replace text:**

1. With the file open in the source editor, make sure that the editor has focus.
2. Optionally, if an instance of the text you want to search for is easily found, you can highlight it now.
3. From the main menu, choose **Search > Find**. Alternatively, press Ctrl+F.
4. In the Find Text Dialog, enter or select the text to locate.
   
   Text previously searched for in this session of the ADF Skin Editor appears in the **Text to Search For** list.
5. Select other search parameters accordingly.
   
   For more information, press F1 or click **Help** from within the dialog.
6. Click **OK**.

**To do a simple search in the open source file for a single text string:**

1. With the file open in the editor, ensure that the editor has focus.
2. Place the cursor in the file at the point you wish to search from.
3. From the main menu, choose **Search > Incremental Find Forward** or **Search > Incremental Find Backwards**.
4. In the dialog, enter the search text.
As you type, the cursor jumps to the next instance of the group of letters displayed.

Alternatively, enter the text string in the search box. As you type, the cursor jumps to the next instance of the group of letters displayed. Use the Previous or Next buttons to search up and down the file. Click in the search box to set Match Case, Whole Word, or Highlight Occurrences.

3.8 Working with Extensions

Extensions are components that are loaded and integrated with the ADF Skin Editor after it starts. Extensions can access the editor and perform many useful tasks. You can add existing extensions into the ADF Skin Editor.

This section contains information on finding and installing extensions. The simplest way to find and download extensions is through the Check for Updates wizard.

If you need additional capabilities, such as integration with a version control system or a special editor, you can add external tools to the ADF Skin Editor. For more information, see Section 3.9, "Adding External Tools to the ADF Skin Editor."

If you want to create a new extension, you can do so in JDeveloper using the Extension JDK from the Oracle Technology Network web page. You can download the completed extension to the ADF Skin Editor.

---

**Note:** Any time an extension is added or upgraded, the migration dialog appears at startup in case you need to migrate any previous settings related to that extension.

3.8.1 How to Install Extensions with Check for Updates

The easiest way to find and install extensions is to use the Check for Updates wizard.

**To install extensions using the Check for Updates wizard:**

1. From the Help menu, select Check for Updates.
2. Follow the steps in the wizard to browse, download, and install patches and extensions.

3.9 Adding External Tools to the ADF Skin Editor

External tools are custom ADF Skin Editor menu items and toolbar buttons that launch applications installed on your system, applications that are not packaged as part of the ADF Skin Editor.

3.9.1 How to Add External Tools to the ADF Skin Editor

You find and add available external tools to the ADF Skin Editor using the External Tools menu.

**To find all external programs that the ADF Skin Editor is preconfigured to support:**

1. From the main menu, choose Tools > External Tools.
2. In the External Tools dialog, click Find Tools.
To add access to an external program from the ADF Skin Editor:
1. From the main menu, choose Tools > External Tools.
2. In the External Tools dialog, click New. Follow the instructions in the wizard.

To change how an external program appears, or remove access to an external program from the ADF Skin Editor:
1. From the main menu, choose Tools > External Tools.
2. In the External Tools dialog, click Edit or Delete. If you are editing the options, display, integration or availability of an external tool from the ADF Skin Editor, select the corresponding tab and change the values. Click Help for help choosing valid values.
3. Click OK. Your changes are reflected immediately.

3.10 Navigating the ADF Skin Editor
You can accomplish any task in the ADF Skin Editor using the keyboard as you use the mouse.

3.10.1 How to Work With Shortcut Keys In the ADF Skin Editor
The ADF Skin Editor comes with several predefined keyboard schemes. You can choose to use one of these, or customize an existing set to suit your own coding style by changing which keyboard shortcuts map to which actions.

To load preset keyboard schemes:
1. From the main menu, choose Tools > Preferences.
2. In the Preferences dialog, select the Shortcut Keys node. For more information at any time, press F1 or click Help from within the Preferences dialog.
3. On the shortcut keys page, click More Actions and then select Load Keyboard Scheme. The Load Keyboard Scheme dialog appears, with the currently loaded keyboard scheme highlighted.
4. In the Load Keyboard Scheme dialog, select the scheme you wish to load and click OK.
5. On the Shortcut Keys page, if you have finished, click OK.

To view the ADF Skin Editor commands and their associated keyboard shortcuts (if assigned):
1. From the main menu, choose Tools > Preferences.
2. In the Preferences dialog, select the Shortcut Keys node.
3. On the Shortcut Keys page, under Available Commands, you can view the complete set of the ADF Skin Editor commands, and what keyboards shortcuts (if any) are assigned to each. If you are looking for a particular command or shortcut, or want to look at shortcuts for a particular category of commands only, enter a filtering expression in the Search field.
4. You can also define new shortcuts, or change existing ones.
To define a new keyboard shortcut for a command within a given keyboard scheme:

1. From the main menu, choose **Tools > Preferences**.

2. In the Preferences dialog, select the **Shortcut Keys** node. For more information at any time, press F1 or click **Help** from within the preferences dialog.

3. On the Shortcut Keys page, under **Available Commands**, select the command that you wish to define a new shortcut for.

4. To define a new shortcut for this action, place focus on the **New Shortcut** field, and then press the key combination on the keyboard.

   If this proposed shortcut already has a command associated with it, that command will now appear in the **Conflicts** field. Any conflicting shortcuts are overwritten when a new shortcut is assigned.

5. To assign this shortcut to the action selected, click **Assign**. If you want to delete an already-assigned shortcut, click the **Delete** button in the toolbar.

   If you want to assign more than one shortcut to a command, select the command and click the **Duplicate** button. Then, type the shortcut key in the **New Shortcut** field and click **Assign**.

6. When you are finished, click **OK**.

To import or export keyboard schemes:

1. From the main menu, select **Tools > Preferences** to open the Preferences dialog.

2. Click **More Actions > Export** or **Import**. Keyboard schemes are stored as XML files.

### 3.10.2 Keyboard Navigation In the ADF Skin Editor

For any action that can be accomplished with a mouse, including selection, there is a way to accomplish the action solely from the keyboard. You can accomplish any task in the ADF Skin Editor using the keyboard as you can using the mouse.

The shortcut keys defined in the Java Look and Feel guidelines provide the base set for the ADF Skin Editor. The various predefined keyboard schemes available in the ADF Skin Editor are then overlaid upon this base set. If the same shortcut key exists in both the look and feel guidelines and the ADF Skin Editor keyboard scheme, the ADF Skin Editor scheme prevails. If a shortcut key defined by the look and feel guidelines does not appear in the ADF Skin Editor scheme, then it is the original look and feel definition that remains in effect when the scheme in question is enabled.

At any given time, then, the shortcut keys enabled in the ADF Skin Editor depend upon the interaction of the currently enabled scheme with the Java look and feel guidelines. When you first open the ADF Skin Editor, the default scheme is enabled. You can change this scheme whenever you wish, and within each scheme, you can customize any of the shortcut key assignments that you would like. Note that any customized shortcuts you create in a scheme are not retained when another predefined keyboard scheme is activated (or even if the same scheme is reloaded).

To load predefined keyboard schemes, view current shortcut assignments within a scheme, and customize those assignments, you will need to open the preferences dialog. To open the dialog, choose **Tools > Preferences** (or on the keyboard, press Alt+T+P) from the main menu and then, using the arrow keys in the left-hand pane, navigate to the **Shortcut Keys** node. For details on working with the dialog, with the page displayed, click **Help** (or on the keyboard press H).
3.10.2.1 Common Navigation Keys
The following table describes the common methods of moving the cursor in the ADF Skin Editor:

<table>
<thead>
<tr>
<th>Key</th>
<th>Cursor Movement</th>
<th>Ctrl+cursor Movement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left Arrow</td>
<td>Left one unit (e.g., a single character)</td>
<td>Left one proportionally larger unit (e.g., a whole word)</td>
</tr>
<tr>
<td>Right Arrow</td>
<td>Right one unit</td>
<td>Right one proportionally larger unit</td>
</tr>
<tr>
<td>Up Arrow</td>
<td>Up one unit or line</td>
<td>Up one proportionally larger unit</td>
</tr>
<tr>
<td>Down Arrow</td>
<td>Down one unit or line</td>
<td>Down one proportionally larger unit</td>
</tr>
<tr>
<td>Home</td>
<td>Beginning of the line</td>
<td>To the beginning of the data (top-most position)</td>
</tr>
<tr>
<td>End</td>
<td>End of the line</td>
<td>To the end of the data (bottom-most position)</td>
</tr>
<tr>
<td>Tab</td>
<td>Next field or control, except when in a text area or field. In this case, press Ctrl+Tab to navigate out of the control. Where there are fields and controls ordered horizontally as well as vertically, pressing Tab moves the cursor first horizontally to the right, then at the end of the line, down to the left of the next line. To the next pane which may be a navigator, an editor, or a window, except when in a text area or field. In this case, press Ctrl+Tab to navigate out of the control</td>
<td></td>
</tr>
<tr>
<td>Shift+Tab</td>
<td>Previous field</td>
<td>To previous tab position. In property sheets, this moves the cursor to the next page</td>
</tr>
<tr>
<td>Enter</td>
<td>Selects and highlights the default button, except when in a combo box, shuttle button, or similar control. n/a</td>
<td></td>
</tr>
</tbody>
</table>

**Note**: The default button changes as you navigate through controls.

3.10.2.2 Navigation In Standard Components
This section describes keyboard navigation in the standard ADF Skin Editor components.

**Buttons**
The following table describes the keyboard actions to perform navigation tasks involving buttons.

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Navigate forward to or from button</td>
<td>Tab</td>
</tr>
<tr>
<td>Navigate backward to or from button</td>
<td>Shift+Tab</td>
</tr>
<tr>
<td>Activate the default button (when the focus is not on a button)</td>
<td>Enter</td>
</tr>
</tbody>
</table>
Navigating the ADF Skin Editor

Table 3–2  (Cont.) Keyboard Navigation for Buttons

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate any button while it has focus</td>
<td>Enter, Spacebar, or keyboard shortcut (if one has been defined)</td>
</tr>
<tr>
<td>Activate Cancel or Close buttons on a dialog</td>
<td>Esc</td>
</tr>
</tbody>
</table>

Checkboxes
The following table describes the keyboard actions to perform navigation tasks involving checkboxes.

Table 3–3 Keyboard Navigation for Checkboxes

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Navigate forward to or from checkbox</td>
<td>Tab</td>
</tr>
<tr>
<td>Navigate backward to or from checkbox</td>
<td>Shift+Tab</td>
</tr>
<tr>
<td>Select or deselect (when the focus is on the checkbox)</td>
<td>Spacebar or keyboard shortcut (if one has been defined)</td>
</tr>
<tr>
<td>Navigate to checkbox and select or deselect (when the focus is not on the checkbox)</td>
<td>Keyboard shortcut (if one has been defined)</td>
</tr>
</tbody>
</table>

Dropdown Lists And Combo Boxes
The following table describes the keyboard actions to perform navigation tasks involving dropdown lists and combo boxes.

Table 3–4 Keyboard Navigation for Dropdown Lists and Combo Boxes

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Navigate forward to or from a combo box or dropdown list</td>
<td>Tab or keyboard shortcut (if one has been defined)</td>
</tr>
<tr>
<td>Navigate backward to or from a combo box or dropdown list</td>
<td>Shift+Tab</td>
</tr>
<tr>
<td>Toggle list open and closed</td>
<td>Spacebar (the current selection receives the focus)</td>
</tr>
<tr>
<td>Open a list</td>
<td>Down Arrow to open (first item on list receives focus)</td>
</tr>
<tr>
<td>Move up or down within list</td>
<td>Up and Down Arrow keys (highlighted value has focus)</td>
</tr>
<tr>
<td>Move right and left within the initial entry on a combo box</td>
<td>Right and Left Arrow keys</td>
</tr>
<tr>
<td>Select list item</td>
<td>Enter</td>
</tr>
<tr>
<td>Note: The first time you press Enter, the item in the list is selected. The second time you press Enter, the default button is activated.</td>
<td></td>
</tr>
<tr>
<td>Close list (with the highlighted value selected)</td>
<td>Esc</td>
</tr>
</tbody>
</table>
**List Boxes**

The following table describes the keyboard actions to perform navigation tasks involving list boxes.

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Navigate forward into or out of a list</td>
<td>Tab</td>
</tr>
<tr>
<td>Navigate backward into or out of list</td>
<td>Shift+Tab</td>
</tr>
<tr>
<td>Make a selection</td>
<td>Up Arrow, Down Arrow, Spacebar, or Enter</td>
</tr>
<tr>
<td><strong>Note:</strong> The first time you press Enter, the highlighted item in the list is selected. The second time you press Enter, the default button is activated.</td>
<td></td>
</tr>
<tr>
<td>Move within list</td>
<td>Up Arrow or Down Arrow</td>
</tr>
<tr>
<td>Move to beginning of list</td>
<td>Home or Ctrl+Home</td>
</tr>
<tr>
<td>Move to end of list</td>
<td>End or Ctrl+End</td>
</tr>
<tr>
<td>Select all entries</td>
<td>Ctrl+A</td>
</tr>
<tr>
<td>Toggle (select or deselect) an item</td>
<td>Spacebar or Ctrl+Spacebar</td>
</tr>
<tr>
<td>Select next item up in list without deselecting item with current focus</td>
<td>Shift+Up Arrow Key</td>
</tr>
<tr>
<td>Select next item down in list without deselecting item with current focus</td>
<td>Shift+Down Arrow Key</td>
</tr>
<tr>
<td>Select current item and all items up to the top of the list</td>
<td>Shift+Home</td>
</tr>
<tr>
<td>Select current item and all items up to the bottom of the list</td>
<td>Shift+End</td>
</tr>
<tr>
<td>Select current item and all items visible above that item</td>
<td>Shift+Page Up</td>
</tr>
<tr>
<td>Select current item and all items visible below that item</td>
<td>Shift+Page Down</td>
</tr>
<tr>
<td>Select item with current focus without deselecting other items (to select items that are not adjacent)</td>
<td>Ctrl+Spacebar</td>
</tr>
<tr>
<td>Navigate through list without deselecting item with current focus</td>
<td>Ctrl+Up Arrow or Ctrl+Down Arrow</td>
</tr>
</tbody>
</table>
Radio Buttons

Table 3–6  Keyboard Navigation for Radio Buttons

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>

<td>Left Arrow or Esc</td>
</tr>
</tbody>
</table>

Panels

The following table describes the keyboard actions to perform navigation tasks involving panels.

Table 3–13 Keyboard Navigation for Panels

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Navigate in/out forward</td>
<td>Tab</td>
</tr>
<tr>
<td>Navigate in/out backward</td>
<td>Shift+Tab</td>
</tr>
</tbody>
</table>
Tables

Arrow keys move focus in the direction of the arrow, except when a web widget has focus; in that case, the down arrow or enter key initiates the widget control action, such as opening a choice list. tab moves the focus right, shift+tab moves the focus left.

The following table describes the keyboard actions to perform navigation tasks involving tables.

| Table 3–14  Keyboard Navigation for Tables |
|----------------|---------------------|
| **Navigation** | **Keys**            |
| Navigate forward in or out of table | Ctrl+Tab            |
| Navigate backward in or out of table | Shift+Ctrl+Tab      |
| Move to next cell (wrap to next row if in last cell) | Tab Arrow or Right Arrow |
| Move to previous cell (wrap to previous row if in first cell) | Shift+Tab or Left Arrow |
| Controls in cells open | Down Arrow or Enter |
| Block move left | Ctrl+Page Up        |
| Block move right | Ctrl+Page Down      |
| Block move up | Page Up             |
| Block move down | Page Down           |
| Move to first cell in row | Home                |
| Move to last cell in row | End                 |
| Move to first cell in table | Ctrl+Home           |
| Move to last cell in table | Ctrl+End            |
| Select all cells | Ctrl+A              |
| Deselect current selection (and select alternative) | Any navigation key |
| Extend selection on row | Shift+Up Arrow      |

Table 3–13 (Cont.) Keyboard Navigation for Panels

<table>
<thead>
<tr>
<th>Navigation</th>
<th>Keys</th>

### 3.11 Working with the Resources Window

The Resources window allows you to create connections to a number of different resources, such as application servers and file systems, from where you can use them in different applications and share them with other users.

When designing and building applications, you may need to find and use many software assets. You may know what you want to find, but you may not be certain where to find it or even what the artifact of interest is called. Even if you think you know where to find the artifact, and what it is called, you might not know how to establish a connection to it.

The Resources window lets you:

- Locate resources stored in a wide variety of underlying repositories through IDE connections
- Locate resources by browsing a hierarchical structure in catalogs
- Search for resources and save searches
- Filter resources to reduce the visible set when browsing
- Use a resource you have found in an application you are building
- Facilitate resource discovery and reuse by sharing catalog definitions

**To open the Resources window:**
In the main menu, choose **Window > Reset Windows to Factory Settings**.

By default, the Resources window is displayed to the right of the ADF Skin Editor window.

**To refresh the Resources window:**
In the Resources window, click **New** and choose **Refresh**.

Alternatively, in the Resources Window choose **Refresh** from the context menu of an object in the My Catalogs panel or the IDE Connections panel.

### 3.11.1 Working with IDE Connections

When you create a connection in the ADF Skin Editor, you can create it as an IDE connection that can be reused in different applications, or shared between users, or as application connections.

IDE connections are globally defined connections available for reuse, and they are listed in the IDE Connections panel of the Resources window. You can copy IDE connections to the Applications window to use them within an application.
IDE connections are listed in the IDE Connections panel of the Resources window. In addition, some types of connections may appear in special connection-type windows. The different types of connections that can be made depend on the technologies and extensions available to you. To see what you can create a connection to, choose IDE Connection from the New button in the Resources window. The specific types of connection you can make depend on the technologies and extensions available to you. The file system location for Resources connection descriptor definition information is system-dir/jdeveloper/systeml2.1.2.n.nn.nn.nn/o.jdeveloper.rescat2.model/connections.xml

To create an IDE connection:
1. In the IDE Connections panel of the Resources window, choose IDE Connection from the New button.
2. Choose the type of connection you want to create, and enter the appropriate information in the Create Connection dialog. For more information at any time, press F1 or click Help from within the dialog.

Once you have created a connection in the Resources window, you can edit details of the connection, but you cannot change the connection name.

To edit an IDE connection:
1. In the IDE Connections panel of the Resources window, choose Properties from the context menu of a connection.
2. The Edit Connection dialog opens where you can change the connection details. For more information at any time, press F1 or click Help from within the Edit Connection dialog.

You can use connections in the Resources window in an application. The connection can be added to the application currently open in the ADF Skin Editor, and it is listed in the Application Resources pane of the Applications window, under the Connections node.

To add a connection to an application:
In the IDE Connections panel of the Resources window, choose Add to Application from the context menu of a connection.
Alternatively, drag the resource from the Resources window and drop it onto an application page.
Alternatively, drag the connection from IDE Connections in the Resources window and drop it onto the Application Resources pane in the Applications window.

3.11.2 How to Search the Resources Window

There are two ways of searching in the Resources window:
- Performing a simple search
- Performing an advanced search, where you enter parameters in a dialog

In addition, you can define a dynamic folder in a catalog where the content of the folder is defined by a query expression that is executed when the folder is opened.
The time the search takes depends on how many resources there are in the Resources window, and how long it takes to connect to them, and the results are displayed in the Search Results panel.

When you perform a simple search, the search is performed across all the contents of the Resources window, and it may take some time because the ADF Skin Editor connects to remote resources during the search.

**To perform a simple search:**

1. In the Resources window, click the Search Options button to choose whether the search is performed against the Name, Type or Description of the resource. For more information at any time, press F1 or click Help from within the Resources window.

2. Enter a search string in the field. For example, if you want to find every resource that contains `dep` in the name, choose Name in Step 1, and enter `dep`. Every resource that contains the string `dep` will be listed in the search results.

3. Click the **Start Search button** to start the search.

Alternatively, you can perform an advanced search where you specify a series of search criteria, and choose where to start the search from.

**To perform an advanced search:**

1. In the Resources window, choose Advanced Search from the context menu of an object in the My Catalogs panel or the IDE Connections panel. For more information at any time, press F1 or click Help from within the Advanced Search dialog.

2. Define where the search starts. Either select from Search in, or click Show Hierarchy which allows you choose within a hierarchical list of the Resources window contents.

3. Enter search criteria to return the resources you want, and click Search.

You can stop a search before it has completed by clicking the **Stop Search button**.

You can save a search and reuse it. There are two ways of saving a search in order to reuse it:

- As a dynamic folder, where the contents of the folder are created dynamically based on the search criteria when the folder is opened.
- As a static folder containing the results of the search.

Dynamic folders can also be created directly in a catalog.

**To save a search:**

1. In the Search Results panel of the Resources window, choose Save Search from the context menu.

2. In the Save Search dialog, choose:
   - **Save Search Criteria**, to create a dynamic folder.
   - **Save Search Results**, to create a static folder of results.

   For more information at any time, press F1 or click Help from within the Resources window.

3. Enter a name for the folder.
4. Choose the catalog to contain the folder, either from the dropdown list, or from the hierarchical list displayed when you click Show Hierarchy.

3.11.3 Filtering Resources Window Contents
Filters allow you fine-tune the contents of catalog folders.

To filter the contents of My Catalogs:
1. In the Resources window, choose Filter from the context menu of an object in the My Catalogs panel or the IDE Connections panel. For more information at any time, press F1 or click Help from within the Filter dialog.
2. Enter a string to define the filtering. Only entries in the folder that contain the string will be shown.

3.11.4 Importing and Exporting Catalogs and Connections
Catalogs and connections are shared by importing Resource catalog archive (.rcx) files that have been exported by another user.

To export a catalog:

Note: When you select a catalog to export, any connections in the catalog are also selected. If you deselect the catalog before exporting, you must be sure to also deselect the connections that are not wanted in the archive file.

1. In the Resources window, choose Export from the context menu of an object in the My Catalogs panel or the IDE Connections panel.
2. In the Export Catalog and Connections dialog, select the catalogs and connections to be exported, and decide how errors will be handled. For more information at any time, press F1 or click Help from within the Export Catalog and Connections dialog.

To import a catalog:
1. In the Resources window, choose Import from (New).
2. In the Import Catalog and Connections dialog, specify or browse to the path and name of the Resource catalog archive file (.rcx). For more information at any time, press F1 or click Help from within the Import Catalog and Connections dialog.
3. Choose the catalogs and connections you want to import, and determine how to handle errors.

3.11.5 Working with Resources Window Catalogs
A catalog is a user-defined construct for organizing resources from multiple underlying repositories. The contents of a catalog and its associated folder structure can be designed to be used by an individual developer, or they can be targeted towards specific groups of users such as the UI designers for a development project.

Catalog folders organize resources in a catalog. You use catalog folders in the same way you would to organize files in a file system or bookmarks in a Web browser. Each catalog folder can contain any combination of:
■ Folders.
■ Dynamic folders, which are populated using a query.
■ Filters, which are used to fine-tune the content of a folder or subtree.

3.11.5.1 Creating Catalogs
You can organize the information in the Resources window in catalogs.

To create a catalog:
1. In the Resources window, choose New Catalog from the New button.
2. In the Create Catalog dialog, specify a name for the catalog. For more information at any time, press F1 or click Help from within the Create Catalog dialog.
3. (Optional) Provide a description for the catalog, and the email of the catalog administrator.

3.11.5.2 Renaming Catalogs
You can rename catalogs.

To rename a catalog:
1. In the Resources window, right-click the catalog, and choose Rename from the context menu.
2. In the Rename dialog, specify a new name for the catalog. For more information at any time, press F1 or click Help from within the Rename dialog.

3.11.6 Working with Catalog Folders
You can create folders to organize the contents of catalogs.

3.11.6.1 How to Create Folders
You can organize the information within catalogs in folders.

To create a catalog folder:
1. In the Resources window, choose New Folder from the context menu of a catalog in the My Catalogs panel or the IDE Connections panel. For more information at any time, press F1 or click Help from within the Create Folder dialog.
2. Enter a name for the folder.

3.11.6.2 How to Create Dynamic Folders
Dynamic Folders provide a powerful way to dynamically populate a catalog folder with resources. The content of the folder is defined by a query expression that is executed when the folder is opened. The results of the query appear as the contents of the folder.

To create a dynamic folder:
1. In the Resources window, choose New Dynamic Folder from the context menu of a catalog in the My Catalogs panel or the IDE Connections panel. For more information at any time, press F1 or click Help from within the Create Dynamic Folder dialog.
2. Define the search criteria that will be used to populate this folder when it is opened.

3.11.6.3 How to Add Resources to a Catalog
You can add a connection from the IDE Connections panel or a resource from the Search panel in the Resources window to a catalog in My Catalogs.

To add a resource to a catalog:
1. In the Resources window, right click a connection in the IDE Connections panel, or the result of a search in the Search panel and choose Add to Catalog from the context menu.

2. The Add to Catalog dialog opens for you to specify the name for the resource in the catalog, and the catalog to add it to. For more information at any time, press F1 or click Help from within the Create Connection dialog.

Alternatively, you can drag an item from under IDE Connections and drop it on a catalog or catalog folder.

You can reorganize a catalog by selecting an item or folder in the catalog and dragging it to another folder in the same catalog, or to another catalog.
This chapter describes how to create the source files for an ADF skin in the ADF Skin Editor and in JDeveloper. Information on how to open an application or project in the ADF Skin Editor that was created in a prior release of JDeveloper and how to import an ADF skin from an ADF Library JAR file is also provided.

This chapter includes the following sections:

- Section 4.1, "About Creating an ADF Skin"
- Section 4.2, "Creating ADF Skin Applications and ADF Skin Projects"
- Section 4.3, "Creating an ADF Skin File"
- Section 4.4, "Importing One or More ADF Skins Into the Current ADF Skin"
- Section 4.5, "Importing ADF Skins from an ADF Library JAR"
- Section 4.6, "Opening an Application Created Outside of the ADF Skin Editor"

### 4.1 About Creating an ADF Skin

An ADF skin defines the properties for the selectors that ADF Faces and ADF Data Visualization components expose. Using the editor in JDeveloper or the ADF Skin Editor, you can create a source file for an ADF skin. As a source file for an ADF skin is a type of CSS file, you could create it without using an editor. However, when you use the editor, associated configuration files get created (the first time that you create an ADF skin) or modified (when you create subsequent ADF skins). For more information about these configuration files, see Section 12.3, "Configuration Files for an ADF Skin."

### 4.2 Creating ADF Skin Applications and ADF Skin Projects

New ADF skin applications and ADF skin projects can be created in the ADF Skin Editor.

#### 4.2.1 How to Create an ADF Skin Application

This section describes how to create an ADF skin application and a project within the application in the ADF Skin Editor.

**To create a new ADF skin application:**

1. From the main menu, choose File > New > ADF Skin Application.
2. In the Create ADF Skin Application dialog, enter application details like the name and directory. For help with the wizard, press F1.
3. Click Next to open the ADF Skin Project page where you specify the name of your ADF skin project and the directory to store it.

4. In the Target Application Release list, select the release of Oracle ADF that the application you want to skin uses.

The ADF Skin Editor configures your ADF skin project appropriately for the release you specify. For example, the ADF Skin Editor filters the list of ADF skins that you can extend from, as described in Section 4.3.1, "How to Create an ADF Skin in the ADF Skin Editor." The ADF Skin Editor also filters the list of skin selectors to display only those that the release you target supports. It will not display a skin selector introduced in a later release if you target your ADF skin project at an earlier release.

5. When you are done, click Finish.

4.2.2 How to Create a New ADF Skin Project

You use the Applications window to keep track of the ADF skin projects (collections of source files for ADF skins, images, and related files) you use while developing your ADF skin application.

You can create a new empty ADF skin project in an ADF skin application.

All ADF skin projects inherit the settings specified in the Default Project Properties dialog. As soon as you create the ADF skin project, it is added to the active ADF skin application.

To create a new ADF skin project:

1. In the Applications window, select the ADF skin application within which the project will appear.

2. Open the Create ADF Skin Project dialog by choosing File > New > ADF Skin Project.

3. In the Create ADF Skin Project dialog, enter project details like the name and directory.

4. In the Target Application Release list, select the release of Oracle ADF that the application you want to skin uses.

The ADF Skin Editor configures your ADF skin project appropriately for the release you specify. For example, the ADF Skin Editor filters the list of ADF skins that you can extend from, as described in Section 4.3.1, "How to Create an ADF Skin in the ADF Skin Editor." The ADF Skin Editor also filters the list of skin selectors to display only those that the release you target supports. It will not display a skin selector introduced in a later release if you target your ADF skin project at an earlier release.

5. When you are done, click Finish.

The new ADF skin project appears in the Applications window. It inherits whatever default properties you have already set. To alter project properties for this project, either double-click the project node or right-click and choose Project Properties.

4.3 Creating an ADF Skin File

You can create an ADF skin file in the ADF Skin Editor or in JDeveloper that defines how ADF Faces and ADF Data Visualization components render at runtime. The ADF skin that you create must extend either one of the ADF skins that Oracle ADF provides.
Creating an ADF Skin File

Creating the Source Files for an ADF Skin

or from an existing ADF skin that you created. The ADF skins that Oracle ADF provides vary in the level of customization that they define for ADF Faces and ADF Data Visualization components. For information about the inheritance relationship between the ADF skins that Oracle ADF provides, see Section 1.4, "Inheritance Relationship of the ADF Skins Provided by Oracle ADF." For information about the levels of customization in the ADF skins provided by Oracle ADF and for a recommendation about the ADF skin to extend, see Section 12.4, "ADF Skins Provided by Oracle ADF."

By default, the design and selectors editors in the ADF Skin Editor and in JDeveloper create ADF skins for the `org.apache.myfaces.trinidad.desktop` render kit. A render kit defines how ADF Faces components map to component tags that are appropriate for a particular client. You can create ADF skins for other render kits by using the source editor in JDeveloper and in the ADF Skin Editor. For example, if you create an ADF skin for an application that renders on handheld devices, you could create the ADF skin for the `org.apache.myfaces.trinidad.pda` render kit. For more information, see Section 12.2, "ADF Skinning Framework and Supported Render Kits."

After you create an ADF skin, you can use the design editor and the other provided editors to modify the values for the selectors that the ADF Faces and ADF Data Visualization components expose. Otherwise, the ADF skin that you create defines the same appearance as the ADF skin from which it extends. For more information, see Chapter 5, "Working with Component-Specific Selectors."

If you create an ADF skin that extends from the Skyros or Fusion Simple families of ADF skins, you enable the design editor. This tab provides an overview pane where you can use controls to set properties for many frequently-used selectors. If the ADF skin that you create extends from the Fusion Simple family of ADF skins, you enable the images editor in addition to the design editor. The images editor provides extra functionality to manage the images associated with the Fusion Simple family of ADF skins. The images editor does not appear if your ADF skin extends from the Skyros family of ADF skins. For more information about using the images editor, see Section 6.5, "Working with the Images Editor." For more information about using the design editor, see Section 3.2, "Working with the ADF Skin Design Editor."

### 4.3.1 How to Create an ADF Skin in the ADF Skin Editor

You can create an ADF skin in the ADF Skin Editor.

**To create an ADF skin in the ADF Skin Editor:**

1. In the Applications window, right-click the project where you want to create the new ADF skin and choose **New > ADF Skin File**.
2. In the Skin File page of the Create ADF Skin dialog, enter the following:
   - **File Name**: Enter a file name for the new ADF skin.
   - **Directory**: Enter the path to the directory where you store the CSS source file for the ADF skin or accept the default directory proposed by the editor.
   - **Family**: Enter a value for the family name of your skin.

You can define a new family or select an existing family by entering a value in the input field. A family groups together ADF skins for an application. You configure an application to use a particular family of ADF skin.

The value you enter must be unique. You can use an EL expression to select an ADF skin for your application at runtime by referencing this value.
Creating an ADF Skin File

3. In the Base Skin page of the Create ADF Skin dialog, specify the following:

- **Use as the default skin family for this project:** Deselect this checkbox if you do not want to make the ADF skin the default for your project immediately.

- **Show Latest Versions Only:** Clear this checkbox to show all available versions of ADF skins.

- **Available Skins:** Select the ADF skin that you want to extend. ADF Faces provides a number of ADF skins that you can extend. The list also includes any ADF skins that you created previously in this project. For more information and a recommendation on the ADF skin to extend, see Section 12.4, "ADF Skins Provided by Oracle ADF."

Note: The value you select for Target Application Release, as described in Section 4.2, "Creating ADF Skin Applications and ADF Skin Projects," determines the list of ADF skins from which you can extend.

- **Skin Id:** A read-only field that displays a concatenation of the value you enter in File Name and the ID of the render kit (desktop) for which you create your ADF skin. You select this value from the Extends list if you want to create another ADF skin that extends from this one.

  The ADF Skin Editor writes the value to the <id> element in the trinidad-skins.xml file.

4. Click Finish.

4.3.2 How to Create an ADF Skin in JDeveloper

You can create an ADF skin in JDeveloper.

**To create an ADF skin in JDeveloper:**

1. In the Applications window, right-click the project that contains the code for the user interface and choose New.

2. In the New Gallery, expand Web Tier, select JSF/Facelets and then ADF Skin, and click OK.

3. In the Skin File page of the Create ADF Skin dialog, enter the following:

- **File Name:** Enter a file name for the new ADF skin.

- **Directory:** Enter the path to the directory where you store the CSS source file for the ADF skin or accept the default directory proposed by the editor.

- **Family:** Enter a value for the family name of your skin.

  You can define a new family or select an existing family by entering a value in the input field. A family groups together ADF skins for an application. You configure an application to use a particular family of ADF skin.

  The value you enter must be unique. You can use an EL expression to select an ADF skin for your application at runtime by referencing this value.

- **Use as the default skin family for this project:** Deselect this checkbox if you do not want to make the ADF skin the default for your project immediately. If you select the checkbox, the trinidad-config.xml file is updated, as described in Section 4.3.3, "What Happens When You Create an ADF Skin."
4. In the Base Skin page of the Create ADF Skin dialog, specify the following:
   - **Show Latest Versions Only**: Clear this checkbox to show all available versions of ADF skins.
   - **Available Skins**: Select the ADF skin that you want to extend. ADF Faces provides a number of ADF skins that you can extend. The list also includes any ADF skins that you created previously in this project. For more information and a recommendation on the ADF skin to extend, see Section 12.4, "ADF Skins Provided by Oracle ADF."
   - **Skin Id**: A read-only field that displays a concatenation of the value you enter in **File Name** and the ID of the render kit (desktop) for which you create your ADF skin. You select this value from the **Extends** list if you want to create another ADF skin that extends from this one.
     
     JDeveloper writes the value to the `<id>` element in the `trinidad-skins.xml` file.

5. Click **Finish**.

### 4.3.3 What Happens When You Create an ADF Skin

If you accepted the default value proposed for the Directory field, a file with the extension `.css` is generated in a subdirectory of the `skins` directory in your project. An ADF skin that extends the Fusion Simple or Skyros family of ADF skins opens in the design editor, as illustrated in Figure 4–1.
An ADF skin that extends an ADF skin not from the Skyros or Fusion Simple families of ADF skin opens in the selectors editor, as illustrated in Figure 4–2. This selectors editor is also available if you create an ADF skin that extends from the Skyros or Fusion Simple family of ADF skin.
Creating an ADF Skin File

Creating the Source Files for an ADF Skin

Figure 4–2 Newly-Created ADF Skin in the Selectors Editor

The trinidad-skins.xml file is modified to include metadata for the ADF skin that you create, as illustrated in Example 4–1, which shows entries for an ADF skin that extends from the Skyros family of ADF skins. Example 4–1 also contains values that specify the render kit and the resource bundle associated with this ADF skin. For more information about resource bundles, see Chapter 7, "Working With Text in an ADF Skin," and for information about the supported render kits, see Section 12.2, "ADF Skinning Framework and Supported Render Kits."

Example 4–1 trinidad-skins.xml File

<?xml version="1.0" encoding="windows-1252"?>
<skins xmlns="http://myfaces.apache.org/trinidad/skin">
   ....
   <skin>
      <id>skin2.desktop</id>
      <family>skin2</family>
      <extends>skyros-v1.desktop</extends>
      <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
      <style-sheet-name>skins/skin2/skin2.css</style-sheet-name>
      <bundle-name>resources.skinBundle</bundle-name>
   </skin>
</skins>

If you select the Use as the default skin family for this project check box in the Create ADF Skin dialog, the trinidad-config.xml file is modified to make the new ADF skin the default skin for your application. This means that if you run the application from JDeveloper, the application uses the newly-created ADF skin. For more information, see Section 11.4, "Applying an ADF Skin to Your Web Application." Example 4–2 shows a trinidad-config.xml file that makes the ADF skin in Example 4–1 the default for an application.

Example 4–2 trinidad-config.xml File

<?xml version="1.0" encoding="windows-1252"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
   <skin-family>skin2</skin-family>
</trinidad-config>
The source file for the ADF skin contains a comment and namespace references, as illustrated in Example 4–3. These entries in the source file for the ADF skin distinguish the file from non-ADF skin files with the .css file extension. A source file for an ADF skin requires these entries in order to open in the design or selectors editors for the ADF skin.

Example 4–3 Default Entries for a Newly-Created ADF Skin File

```/*ADFFaces_Skin_File / DO NOT REMOVE**/
@namespace af "http://xmlns.oracle.com/adf/faces/rich";
@namespace dvt "http://xmlns.oracle.com/dss/adf/faces";
```

The first time that you create an ADF skin in your project, a resource bundle file (skinBundle.properties) is generated, as illustrated in Figure 4–2. For more information about using resource bundles, see Chapter 7, "Working With Text in an ADF Skin."

### 4.4 Importing One or More ADF Skins Into the Current ADF Skin

You can import another ADF skin that is in your ADF skin project into your ADF skin using the @import rule. This makes the style properties defined in the latter ADF skin available to your ADF skin. The following examples demonstrate the valid syntax to import an ADF skin (skinA) into the current ADF skin:

```/** Use the following syntax if skinA.css is in the same directory **/
@import "skinA.css";
@import url("skinA.css");

/** Use the following syntax if skinA.css is in another directory **/
@import "./skinA/skinA.css";
@import url("./skinA/skinA.css");
```

The @import rule(s) must follow all @charset rules and precede all other at-rules and rule sets in an ADF skin, as shown in the following example that imports two ADF skins into the current ADF skin:

```@charset "UTF-8";
@import url("./skinA/skinA.css");
@import url("./skinB/skinB.css");

/**ADFFaces_Skin_File / DO NOT REMOVE**/
@namespace af "http://xmlns.oracle.com/adf/faces/rich";
@namespace dvt "http://xmlns.oracle.com/dss/adf/faces";
```

```af|inputText{
    background-color: Green;
}
...```

### 4.5 Importing ADF Skins from an ADF Library JAR

You can import ADF skins that have been packaged in a JAR file into your ADF skin project. When you import an ADF skin from a JAR file into your project, the imported ADF skin is available to extend from when you create a new ADF skin, as described in Section 4.3, "Creating an ADF Skin File."
The recommended type of JAR file to use to package an ADF skin is an ADF Library JAR file. For information about how to package an ADF skin into this type of JAR file, see Section 11.3, "Packaging an ADF Skin into an ADF Library JAR."

4.5.1 How to Import an ADF Skin from an ADF Library JAR

You can import ADF skins into your project that have been packaged in a JAR file.

To import an ADF skin from an ADF Library JAR:

1. From the main menu, choose Application > Project Properties.
2. In the Project Properties dialog, select the Libraries and Classpath page and click Add JAR/Directory.
3. In the Add Archive or Directory dialog, navigate to the JAR file that contains the ADF skin you want to import and click Select.

The JAR file appears in the Classpath Entries list.
4. When finished, click OK.

4.5.2 What Happens When You Import an ADF Skin from an ADF Library JAR

The ADF skin(s) that you import from the JAR file appear in the Extends list when you create a new ADF skin, as described in Section 4.3, "Creating an ADF Skin File." After you create a new ADF skin by extending an ADF skin that you imported from a JAR file, the Extended Skins list in the selectors editor's Preview Pane displays the name of the ADF skin that you imported. For example, in Figure 4–3 the skin2.css ADF skin has been created by extending the ADF skin, jarredskin.css, that was imported into the project from a JAR file.

Figure 4–3 Imported ADF Skin in the Extended Skins List

Properties that have been defined in the ADF skin that you imported appear with a blue upward pointing arrow in the Properties window. An information tip about the inheritance relationship displays when you hover the mouse over the property, as illustrated in Figure 4–4.

Figure 4–4 Property Inherited from an Imported ADF Skin
4.6 Opening an Application Created Outside of the ADF Skin Editor

When you open an application or project that was created in a prior release of JDeveloper, the ADF Skin Editor prompts you to migrate the project to JDeveloper 12c format. Depending on the content of the project, the ADF Skin Editor may display additional prompts to migrate some specific source files as well. Oracle recommends that you make a backup copy of your projects before you open them in the ADF Skin Editor or migrate them using the ADF Skin Editor.
This chapter describes how to change the appearance of ADF Faces and ADF Data Visualization components by specifying properties for the selectors that the ADF skinning framework exposes for these components. Features such as the ability to configure ADF skin properties to apply to messages, themes that you can apply to ADF Faces components, and how to configure an ADF skin for accessibility are also described.

This chapter includes the following sections:

- Section 5.1, "About Working with Component-Specific Selectors"
- Section 5.2, "Changing ADF Faces Components’ Selectors"
- Section 5.3, "Changing ADF Data Visualization Components’ Selectors"
- Section 5.4, "Changing a Component-Specific Selector"
- Section 5.5, "Configuring ADF Skin Properties to Apply to Messages"
- Section 5.6, "Applying Themes to ADF Faces Components"
- Section 5.7, "Configuring an ADF Skin for Accessibility"

### 5.1 About Working with Component-Specific Selectors

You customize the appearance of an ADF Faces component or ADF Data Visualization component by defining style properties for the selectors that the component exposes. To achieve the appearance you want, you need to become familiar with the component-specific selectors that the ADF Faces and ADF Data Visualization components expose, plus the global selector aliases and descendant selectors that a component-specific selector may reference. The ADF skins that you extend from when you create an ADF skin define many global selector aliases and descendant selectors. You also need to become familiar with the component itself and how it relates to other components. For example, customizing the appearance of the ADF Faces table component shown in Figure 5–1 requires you to define style properties for selectors exposed by the af:column component in addition to selectors exposed by the ADF Faces table component. You may also need to modify the style properties for one or more of the icon or message global selector aliases that the ADF skin you extend defines.
About Working with Component-Specific Selectors

Use the tools that the selectors editor for ADF skins provides to customize the appearance of the ADF Faces components and ADF Data Visualization components. For more information, see Chapter 3, "Working with the ADF Skin Editor."

Other sources of information that may help you as you change the selectors of ADF Faces and ADF Data Visualization components include the following:

- **Images**: An ADF skin can reference images that render icons and logos, for example, in a page. For more information about how to work with images in an ADF skin, see Chapter 6, "Working with Images and Color in Your ADF Skin."

- **Text**: An ADF skin does not include text strings that render in your page. However, you can specify a resource bundle that defines the text strings you want
Changing ADF Faces Components' Selectors

ADF Faces components render user interface controls, such as buttons, links and check boxes in your Fusion web application. ADF Faces components also include components that render calendars, panels to arrange other user interface controls and tables in your web application. For more information about ADF Faces components and the functionality that they provide, see Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

You can change the runtime appearance of ADF Faces components by editing the properties that each ADF Faces skin selector exposes. The number of selectors that an ADF Faces component exposes varies by component. For example, the ADF Faces components, af:image and af:popup, expose one selector each. In contrast, the ADF Faces component, af:panelHeader, exposes a variety of selectors that enable you to change the appearance of different parts of the user interface of that component. There are, for example, selectors that allow you to change the af:panelHeader component's instruction text, help icons, and titles.

The process to follow to change the runtime appearance of an ADF Faces component is the same for each component; the only difference is the number of selectors that each ADF Faces component exposes. Figure 5–2 and Figure 5–3 take the button component as an example and illustrate how you can customize the appearance of this component using pseudo-elements and the component's selector. Figure 5–2 shows the application of the skyros skin on the button component and the component icon.

Figure 5–2 Button Component Default Appearance with Skyros ADF Skin

![Button Component Default Appearance with Skyros ADF Skin](image)

Figure 5–3 shows the appearance of the component after you set values for the following pseudo-elements on the component's selector:

- **access-key**: The Color property is set to red
- **dropdown-icon-style**: The Border property is set to 2px solid black
Reference information about the selectors that ADF Faces components expose can be found in the Tag Reference for Oracle ADF Faces Skin Selectors (for the release that pertains to the application you are skinning).

5.3 Changing ADF Data Visualization Components' Selectors

The ADF Data Visualization components are a set of components that provide functionality to represent data in graphical and tabular formats. Examples of the ADF Data Visualization components include the following: graph, gantt, pivot table, and hierarchy viewer. For more information about ADF Data Visualization components and the functionality that they provide, see Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

You can change the runtime appearance of ADF Data Visualization components by editing the properties that each ADF Data Visualization component selector exposes. The number of selectors exposed by an ADF Data Visualization component varies by component.

Figure 5–4 shows an ADF skin with the nodes expanded to show the selectors that you can customize for the ADF Data Visualization gauge component.
You customize the appearance of ADF Data Visualization components by defining style properties for the selectors that each ADF Data Visualization component exposes. Using the tools provided by JDeveloper’s selectors editor for ADF skins or the ADF Skin Editor, you customize the appearance of the ADF Data Visualization components. For more information, see Chapter 3, "Working with the ADF Skin Editor."

To achieve the appearance you want, you need to become familiar with the selectors that the ADF Data Visualization component exposes, the global selector aliases that the component may reference and which are defined in the ADF skin that you extend when you create an ADF skin. You also need to become familiar with the component itself and how it relates to other components. For example, customizing the appearance of the ADF Data Visualization pivotTable component shown in Figure 5–5 requires you to define style properties for this selector’s pseudo-elements. You may also need to modify the style properties for one or more of the global selector aliases that the ADF skin you extend defines.

Many ADF Data Visualization component selectors, such as the selectors for the graph and hierarchyViewer components, expose pseudo-elements for which you configure ADF skin properties. These ADF skin properties modify the appearance of the area specified by the pseudo-element. The characters -tr- preface the names of ADF skin properties. For example, Figure 5–6 shows the properties of the hierarchy viewer’s lateral-navigation-button selector, all of which are prefaced by -tr-.
In contrast, the *gantt* component’s summary-task-left selector, shown in Figure 5–7, exposes only four ADF skin properties (-tr-rule-ref, -tr-inhibit-, and so on) as the majority of the properties that you configure for this selector are CSS properties.

For more information about ADF skin properties, see Section 2.3, "Properties in the ADF Skinning Framework."

Reference information about the selectors, pseudo-elements, and pseudo-classes that ADF Data Visualization components expose can be found in the Oracle Fusion...
Changing a Component-Specific Selector

The process to change a component-specific selector is the same for both the ADF Faces and ADF Data Visualization components. In the Selector Tree of the selectors editor, you expand the Faces Components Selectors or Data Visualization Selectors node to select the selector of the component you want to modify. You then set values for this selector using the Properties window. You can also set properties for any pseudo-elements, component style classes, component selector aliases, or descendant selectors that the selector you select references. In addition, you can add pseudo-classes that the component-specific supports. For more information about pseudo-classes, see Section 2.2, "Pseudo-Classes in the ADF Skinning Framework." Figure 5–8 shows a view of the skin selector for the ADF Faces table component in the Selector Tree with the different items that you can configure for this skin selector.

Figure 5–8 Selector for the table Component

Figure 5–9 shows a runtime view of an ADF Faces table component that renders data using the style properties provided by the ADF Faces simple skin.
5.4.1 How to Change a Component-Specific Selector

You change a component-specific selector by selecting the selector in the Selector Tree and setting values for the selector, its pseudo-elements, or descendant selectors in the Properties window. In addition, you can add a pseudo-class if the component-specific selector supports one.

To change a component-specific selector:

1. In the Selector Tree of the selectors editor, choose the appropriate option:
   - Expand the Faces Component Selectors node if you want to change a selector for an ADF Faces component.
   - Expand the Data Visualization Selectors node if you want to change a selector for an ADF Data Visualization component.

   For example, expand the Faces Component Selectors node, the Column node, the Pseudo-Elements node, and select the `column-header-cell` selector.

2. In the Properties window, specify values for the properties that the selector you selected in Step 1 supports.

   For example, in the Common section of the Properties window, specify values for the following attributes:
   - **Background Color**: Specify the background color that you want to appear in the header row of the table.
   - **Color**: Specify the color that you want to apply to text that appears in the header row of the table’s column.

3. In the Preview Pane, click the Add Pseudo-Class icon to choose a supported pseudo-class from the displayed list of supported pseudo-classes that appears.

5.4.2 What Happens When You Change a Component-Specific Selector

The selectors editor displays the changes that you make to the selector after you click the Refresh icon in the Preview Pane. If you add a pseudo-class to the selector, the Preview Pane also displays an entry for the selector with the added pseudo-class. For example, Figure 5–10 shows an entry for a selector with the :hover pseudo-class added.

**Note**: The Preview Pane for the `af|document` selector only displays one entry even if you add a pseudo-class to this selector.
Configuring ADF Skin Properties to Apply to Messages

Figure 5–10  Preview Pane with a Component Specific Selector and a Pseudo-Class

The selectors editor also writes the values that you specify for the selectors in the Properties window to the source file for the ADF skin. Example 5–1 shows the changes that appear in the source file after making some of the changes described in Section 5.4.1, "How to Change a Component-Specific Selector."

Example 5–1  Selector Values to Skin the Header Row in a Column

```af|column::column-header-cell
{
  color: Black;
  background-color: Olive;
  font-weight: bold;
}
```

When a web application uses an ADF skin that contains the values shown in Example 5–1, header rows in the columns of a table rendered by the ADF Faces table component appear as illustrated by Figure 5–11 where the table uses a skin that extends the simple skin.

Figure 5–11  ADF Faces table with a Header Row Skinned

<table>
<thead>
<tr>
<th>PersonID</th>
<th>PrincipalName</th>
<th>Title</th>
<th>FirstName</th>
<th>LastName</th>
</tr>
</thead>

</tbody>
</table>

5.5 Configuring ADF Skin Properties to Apply to Messages

You can apply styles to ADF Faces input components based on whether or not the input components have certain types of message associated with them. When a
message of a particular type is added to a component, the styles of that component are automatically modified to reflect the new status. If you do not define styles for the type of message in question, the component uses the default styles defined in the ADF skin.

The types of message property are:

- :fatal
- :error
- :warning
- :confirmation
- :info

Figure 5–12 shows an inputText component rendered using the simple ADF skin. In Figure 5–12, the simple ADF skin defines style values for the :warning message property to apply to the inputText component when an end user enters values that generate a warning.

Figure 5–13 shows the same inputText component as in Figure 5–12. In Figure 5–13, the end user entered a value that generated an error. As a result, the inputText component renders using the style properties configured for the :error message property.

The ADF skinning framework defines a number of global selector aliases that define style properties to apply to messages. Figure 5–14 shows a list of global selector aliases under the Message node in the Selector Tree. The Preview Pane, on the right of Figure 5–14, shows how the style properties defined for the global selector alias currently selected in the Selector Tree render the component selected from the View as list.
You can customize the global selector aliases that the ADF skinning framework provides for messages by defining style properties in your ADF skin. The style properties that you define for the global selector alias affect all ADF Faces components that reference the global selector alias. For example, if you change the border color for the global selector alias shown in Figure 5–14 to green, all the ADF Faces components shown in the View as list render with a border that is green. For more information about global selector aliases, see Chapter 8, "Working With Global Selector Aliases."

For more information about configuring messages for ADF Faces components, see the "Displaying Tips, Messages, and Help" chapter in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

5.5.1 How to Configure an ADF Skin Property to Apply to a Message

You add a pseudo-class to the component's selector for the message type that you want to configure. You then define style properties for the pseudo-class using the Properties window.

To configure an ADF skin property to apply to a message:

1. In the Selector Tree of the selectors editor, expand the Faces Component Selectors section and select the selector for the ADF Faces component for which you want to configure the style properties to apply to a message.
   
   For example, select the af inputText selector to configure the style properties to apply to the ADF Faces inputText component.
   
2. Click the Add Pseudo-Class icon to display a list of the available pseudo-classes for the selector that you selected in Step 1.
   
3. Select the pseudo-class that corresponds to the message for which you want to configure style properties. The following pseudo-classes are available for the ADF Faces components:
   
   - fatal
   - error
   - warning
   - confirmation
   - info
4. Configure the style properties that you want to apply to the component at runtime when the application displays a message with the component.

5.5.2 What Happens When You Configure ADF Skin Properties to Apply to Messages

The selectors editor writes the values that you specify for the selector’s pseudo-class in the Properties window to the source file for the ADF skin. For example, assume that you set the value of the Border Color property to Red for the af|inputText selector’s error pseudo-class. Figure 5–15 shows the change that appears in the source file and in the Preview Pane of the ADF skin.

*Figure 5–15  Style Properties for an inputText Component’s Error Message*

If you want to define style properties to appear when the component displays an error message, use the error pseudo class. For example, set the content pseudo element’s background color property for the af:inputText component’s to Red when an error occurs as follows:

```xml
af|inputText::content:error
{
  background-color: Red;
}
```

5.6 Applying Themes to ADF Faces Components

Themes are a way of implementing a look and feel at a component level. A theme’s purpose is to provides a consistent look and feel across multiple components for a
portion of a page. Common uses for themes are in JSF page templates to define a distinct look for certain areas or to create a layered layout in an application. For example, a page may have a branding area at the top with a dark background and light text, a navigation component with a lighter background, and a main content area with a light background.

A component that sets a theme exposes that theme to its child components and therefore the theme is inherited. Themes can be set (started or changed) by the af:document and af:decorativeBox components.

The Fusion ADF skins support the following themes:

- dark
- medium
- light
- None (default)

You can also create your own theme by entering syntax similar to the following in the source file of an ADF skin:

```xml
<af:document theme=UserCreated />
```

Figure 5–16 shows how the selectors editor renders tabs where you can configure style properties for each theme provided by the Fusion ADF skins in addition to a user-created theme.

![Tabs in the Selectors Editor for Themes](image)

Figure 5–16 Tabs in the Selectors Editor for Themes

Figure 5–17 shows how the different themes contrast to each other.

![Default Appearance of Themes](image)

Figure 5–17 Default Appearance of Themes

In addition to the themes listed previously, there is one other theme (contentBody) that the af:decorativeBox selector uses, as shown in Figure 5–18. The af:decorativeBox component is the only component that ever renders using the style properties defined for this theme.
In your application, you start the theme by specifying it as an attribute of the af:document component in the JSF page, as shown in the following example:

```xml
<af:document theme="dark">
    <af:panelTabbed>...</af:panelTabbed>
</af:document>
```

**Note:** You can also start a theme by specifying it as an attribute of the af:decorativeBox component.

You can prevent a component inheriting modifications made to a parent component. For example, you can prevent the af:panelTabbed child component inheriting the dark theme defined for the af:document parent component in the JSF page. For more information, see the Section 5.6.3, "How to Prevent a Component Inheriting a Theme from a Parent Component."

By default, themes are not set for components or their child components. Because themes are inherited, the following values are supported when a component has a theme attribute that is not set:

- **not given** - If no theme is given, the theme is inherited, as in
  ```xml
  <af:decorativeBox>...
  ```
- **#{null}** - The theme is inherited; same as not given.
- **inherit** - The theme is inherited; same as null.
- **default** - The theme is removed for the component and its child components.
- **empty string** - If the theme is set to a blank string, it has the same behavior as default. For example, `<af:decorativeBox theme=""/>` will remove the theme for the component and its child components.

Because the themes are added to every HTML element of a component that supports themes and that has style classes, there is no need for containment-style CSS selectors for themes. With the exception of :ltr and :rtl, all theme selectors should always appear on the last element of the selector. For example, the selector to apply a dark theme to each step of an af:breadCrumbs component is:

```css
af|breadCrumbs::step:disabled[theme='dark'] {
    color:#FFFFFF;
}
```

To do the same in a right-to-left environment, use the following selector:

```css
af|breadCrumbs::step:disabled[theme='dark']::rtl {
    color:#FFFFFF;
}
```
Color incompatibility may occur if a component sets its background color to a color that is not compatible with its encompassing theme color. For example, if a \texttt{panelHeader} component is placed in a dark theme, the CSS styles inside the \texttt{panelHeader} component will set its component background to a light color without changing its foreground color accordingly. The result is a component with a light foreground on a light background. Many other components also set their foreground color to a light color when placed in a dark theme.

If color incompatibility occurs, you can resolve color incompatibility between parent and child components by setting a value for the `-tr-children-theme` property. For components that do not have a parent-child relationship, you can manually set the component’s theme color to a color that is compatible with the surrounding theme color. You do this by inserting the \texttt{panelGroupLayout} or \texttt{panelStretchLayout} component inside the component and by setting the \texttt{panelGroupLayout} or \texttt{panelStretchLayout} theme to a compatible color.

```xml
<af:panelHeader text="Header Level 0">
  <af:panelGroupLayout layout="vertical" theme="default">
    ...
  </af:panelGroupLayout>
</af:panelHeader>
```

### 5.6.1 How to Enable Themes for Components

You enable themes on a per-component basis in an ADF skin. Enabling themes on a per-component basis means that you do not generate unnecessary HTML attributes that the ADF skin will not use.

**To enable themes for components:**
- In the source editor, enter syntax for the component’s selector to enable themes for the component in the ADF skin. For example, to enable theme support in an ADF skin for the \texttt{outputLabel} component, enter the following:

  ```xml
  af|outputLabel {
    -tr-enable-themes: true;
  }
  ```

### 5.6.2 How to Set Theme Properties for a Component in an ADF Skin

You set theme properties for a component using the tab in the selectors editor that corresponds to the theme you want to configure.

**To set theme properties for a component in an ADF skin:**
1. In the Selector Tree of the selectors editor, expand the appropriate node for which you want to set theme properties.

   You can configure items under the Style Classes, Faces Component Selectors, and Data Visualization Component Selectors nodes.

2. Click the tab that corresponds to the theme for which you want to set properties.

   For example, if you want to set a property for the dark theme, click \textbf{Dark Theme}, as shown in Figure 5–19.
3. In the Properties window, set values for the properties that you want to configure for the selected theme.

Example 5–2 shows the entry that appears in the source file of an ADF skin if you set the background-color property of the af:panelTabbed component’s dark theme to Red.

Example 5–2  Defining a Theme for a Component in an ADF Skin

```css
af|panelTabbed[theme="dark"] { 
  background-color: Red;
}
```

5.6.3 How to Prevent a Component Inheriting a Theme from a Parent Component

If you do not want a child component to inherit modifications made to a parent component in a JSF page, set a value for the -tr-children-theme property in the source file of the ADF skin. For example, you do not want the af:panelTabbed child component to inherit the dark theme defined for the af:document parent component in the JSF page. Set the -tr-children-theme property in the source file for the ADF skin as shown in Example 5–3.

Note that if you do not want a component to inherit modifications for a specific theme, you must specify the themed version. In Example 5–3, this is the dark theme. If you wanted to prevent the inheritance of modifications for the medium theme, you also set the -tr-children-theme property in the source file for the medium theme.

Example 5–3  Child Component Preventing Inheritance of a Theme from a Parent Component

```css
af|panelTabbed[theme="dark"] { 
  -tr-children-theme: default;
}
```

5.7 Configuring an ADF Skin for Accessibility

Oracle ADF provides application accessibility support to make applications developed using ADF Faces components usable for persons with disabilities. You can define style properties in your ADF skin specifically for persons with disabilities as part of efforts to make your application accessible. You preface these style properties with the @accessibility-profile rule.

The @accessibility-profile rule allows you to define style properties for the high-contrast and large-fonts accessibility profile settings that you can specify
Configuring an ADF Skin for Accessibility

in the trinidad-config.xml file. For more information about the trinidad-config.xml file, see Section 12.3, "Configuration Files for an ADF Skin."

Define style properties for the high-contrast accessibility profile where you want background and foreground colors to contrast highly with each other. Define style properties for the large-fonts accessibility profile for cases where the user must be allowed to increase or decrease the text scaling setting in the web browser. Defining large-fonts does not mean that the fonts are large, but rather that they are scalable fonts or dimensions instead of fixed pixel sizes.

Example 5–4 shows style properties that get applied to the af|column::sort-ascending-icon pseudo-element when an application renders using the high-contrast accessibility profile.

Example 5–4 Style Properties Defined Using the @accessibility-profile

@accessibility-profile high-contrast {
  af|column::sort-ascending-icon {
    content: url("/afr/fusion/sort_asc_ena.png");
  }
  af|column::sort-ascending-icon:hover {
    content: url("/afr/fusion/sort_asc_ovr.png");
  }
  af|column::sort-ascending-icon:active {
    content: url("/afr/fusion/sort_asc_selected.png");
  }
  af|column::sort-descending-icon {
    content: url("/afr/fusion/sort_des_ena.png");
  }
  af|column::sort-descending-icon:hover {
    content: url("/afr/fusion/sort_des_ovr.png");
  }
  af|column::sort-descending-icon:active {
    content: url("/afr/fusion/sort_des_selected.png");
  }
  af|column::sorted-ascending-icon {
    content: url("/afr/fusion/sort_asc_selected.png");
  }
  af|column::sorted-descending-icon {
    content: url("/afr/fusion/sort_des_selected.png");
  }
}

For more information about developing accessible ADF Faces pages and accessibility profiles, see the "Developing Accessible ADF Faces Pages" chapter in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

5.7.1 How to Configure an ADF Skin for Accessibility

You define style properties for the selector or selector’s pseudo-elements that you want to configure and preface these style properties with the @accessibility-profile rule.

To configure an ADF skin for accessibility:

1. Define style properties for the selectors and selectors’ pseudo-elements that you want to configure, as described in Section 5.4, "Changing a Component-Specific Selector."
2. In the source file for the ADF skin, preface the skinning keys that you configured with the `@accessibility-profile` rule, as illustrated in Example 5-4.
This chapter describes how to work with images and color in an ADF skin. Features, such as how you change images using the provided editors, are described in addition to how to work with the color categories in a Skyros-extended skin to quickly change the color palette that your ADF skin defines.

This chapter includes the following sections:

- Section 6.1, "About Working with Images and Color in Your ADF Skin"
- Section 6.2, "Changing Images and Colors in the ADF Skin Design Editor"
- Section 6.3, "Working with Color in a Skyros-Extended ADF Skin"
- Section 6.4, "Changing an Image for a Component Selector"
- Section 6.5, "Working with the Images Editor"
- Section 6.6, "Providing a Simple Border Style for ADF Skins"

### 6.1 About Working with Images and Color in Your ADF Skin

Apart from the simple skin which contains only minimal formatting, the ADF skins provided by Oracle ADF define color schemes and reference images to provide a colorful look and feel for applications. Changing these colors and the images that your ADF skin references is a task that will make a significant difference to the appearance of the application that uses your ADF skin. Figure 6–1 illustrates this point by showing the same page from an application that renders using two different ADF skins (skyros and simple).
Among the selectors in the ADF skins provided by Oracle ADF that reference images are those in the following list. A short description of the role that the referenced images performs in skinning the Fusion web application also appears.

- `af|document::splash-screen-icon`
  This component-specific selector specifies the icon that appears within a splash screen when a Fusion web application loads in a browser.

- `af|column::sorted-descending-icon-style`
  This component-specific selector specifies the icon that renders for the sorted descending indicator in a column.

- `.AFFatalIcon:alias`
  This global selector alias specifies the icon to appear if a fatal error occurs on a page.

Examples of colors that the ADF skins provided by Oracle ADF define include the `.AFBrightBackground:alias` (used only by Fusion Simple skins) and `.APHoverPrimaryColor:alias` (used only by Skyros skins) global selector aliases. These global selector aliases define the background color when, for example, a user hovers a cursor over a button component. Another example is the `.APBackgroundColor:alias` global selector alias used by Skyros skins to define the background color used for the main content area of your page.

The ADF Skin Editor provides features to help change the colors and images that your ADF skin uses. The availability of some or all of these features depends on the family of ADF skin that you extend, as described in the following list:

- If your ADF skin extends the Skyros or Fusion Simple families of skin
  The ADF Skin Editor enables the design editor where you can use various color pickers and other controls to change some of the more frequently used colors and images in an ADF skin. For more information, see Section 6.2, "Changing Images and Colors in the ADF Skin Design Editor."

- If your ADF skin extends from the Fusion Simple family of skin
The ADF Skin Editor enables the images editor that provides additional tools to manage colors and images. For more information, see Section 6.5, "Working with the Images Editor."

■ If your ADF Skin extends from the Fusion or Simple families of skin

Use the selectors editor to change images, as described in Section 6.4, "Changing an Image for a Component Selector."

### 6.2 Changing Images and Colors in the ADF Skin Design Editor

The design editor appears when you create an ADF skin that extends from the Skyros or Fusion Simple families of ADF skins. You access it by clicking the Design tab of the open ADF skin. For an overview of the design editor, see Section 3.2, "Working with the ADF Skin Design Editor."

Examples of tasks that you can carry out using this editor include the following:

■ Change the default text color in ADF skins that extend from Skyros

■ Change the background color that appears to highlight when you hover over components such as the button component

■ Replace icons

You can change all or individual icons for components, status, and animation icons using the Replace Icons dialog that you invoke when you click one of the Status Icon, Animations, or Component buttons in the Images area of the General tab. For more information, click Help on the Replace Icons dialog.

**Note:** The Component button and the associated dialog to replace component icons does not appear if your ADF skin extends from the Fusion Simple family.

*Figure 6-2* shows an ADF skin that extends from the Skyros family of ADF skin where the following changes have been made:

■ In the General tab

**Note:** Red rectangles in *Figure 6-2* identify the controls used to make the changes in the General tab. Red arrows point to a corresponding result in the sample page.

- Change the main default text color to Fuchsia

  This changes the color value of the AFTextColor global selector alias which is an anchor color. This change also affects the global selector aliases (for example, AFTextPrimaryColor and AFTextSecondaryColor) that set color properties which derive their hue value from the AFTextColor global selector alias. For more information about this relationship, see Section 6.3, "Working with Color in a Skyros-Extended ADF Skin."

- Change the primary accent color to Black

  This changes the color that renders when a cursor hovers over a component such as a button component. The global selector aliases that sets this color property are AFHoverPrimaryColor and AFButtonGradientStartHoverColor. Other global selector aliases use
Working with Color in a Skyros-Extended ADF Skin

the AFButtonGradientStartHoverColor global selector alias to derive the hue value of the color properties that they set. Examples of global selector aliases that derive their color property from the AFButtonGradientStartHoverColor global selector alias include AFButtonBorderBottomHoverColor and AFButtonBorderHoverColor. For more information about this relationship, see Section 6.3, "Working with Color in a Skyros-Extended ADF Skin."

- Change one of the animated icons that indicate connection status

In this example, the animation icon referenced by the af|statusIndicator::idle-icon was changed.

In the Branding Area tab

- Change the color property that determines the background color for the branding area (AFBrandingBackgroundColor global selector alias) to transparent.
- Change the image file that is used to render the logo in the branding area.

Figure 6–2 Changing Colors and Icons in ADF Skin Design Editor

6.3 Working with Color in a Skyros-Extended ADF Skin

An ADF skin that extends from the Skyros family of ADF skin defines global selector aliases that group colors into one of three categories, as illustrated in Figure 6–3. Changing the value of color properties for global selector aliases categorized as anchor colors can help you to quickly change the color palette that your ADF skin defines.
Working with Color in a Skyros-Extended ADF Skin

6-5

Figure 6–3  Color Categories Skyros’s Global Selector Aliases

- **Anchor Color:** These global selector aliases define the base colors for your ADF skin. For example, the `AFButtonGradientStartActiveColor` global selector alias defines the start gradient background color for buttons that have an active state.

- **Derivative Color:** These global selector aliases derive the hue value for their color properties from anchor colors. The global selector aliases in Example 6–1 all derive their hue value from the `AFButtonGradientStartActiveColor` global selector alias. The ADF Skin Editor propagates any change that you make to the anchor color to the derivative color. The derivative colors inherit any change that you make to an anchor color using the ADF Skin Editor.

- **Speciality Color:** These global selector aliases define color properties that do not derive their hue value from anchor colors and are not anchor colors for other colors. For example, the `AFCarouselFocusBorderColor` global selector alias that defines the border color when the carousel component has focus.

Figure 6–4 shows the result of changing the default value of the `AFButtonGradientStartActiveColor` global selector alias. The ADF Skin Editor also updates the values of the derivative colors that derive their hue value from the anchor color.
If you change the color property of a derivative color and later make a change to the associated anchor color, the ADF Skin Editor displays a dialog to warn you that the change you make to the anchor color will override the change that you made to the derivative color, as illustrated in Figure 6–5. Click OK to make the change to the anchor color and to override the already-defined value for the derivative color.
Example 6–1 shows entries from the Skyros ADF skin (skyros-v1-desktop.css) that define the default values for the AFWButtonGradientStartActiveColor global selector alias and its associated derivative colors. These global selector aliases share the same hue value (209) but specify different values for the saturation and lightness values.

Example 6–1  Global Selector Aliases with Anchor and Derivative Colors in Skyros

/* Anchor, hsl(209, 56%, 63%), #6AA1D5 */
.AFWButtonGradientStartActiveColor:alias {
    color: #6AA1D5;
}

/* Derivative of AFWButtonGradientStartActiveColor, hsl(209, 32%, 54%), #648BAF */
.AFWButtonBorderTopActiveColor:alias {
    color: #648BAF;
}

/* Derivative of AFWButtonGradientStartActiveColor, hsl(209, 39%, 62%), #789FC4 */
.AFWButtonBorderActiveColor:alias {
    color: #789FC4;
}

/* Derivative of AFWButtonGradientStartActiveColor, hsl(209, 54%, 79%), #ACCAE6 */
Example 6–2 shows the same global selector aliases referenced in Example 6–1. In Example 6–2, an ADF skin extends from Skyros and changes the value of the color property of the AFButtonGradientStartActiveColor global selector alias to #6CD5A1. The ADF Skin Editor modifies the color properties of the global selector aliases that derive their color value from the anchor color.

### Example 6–2 Modified Anchor and Derivative Colors
```
.AFButtonGradientStartActiveColor:alias {
  color: #6CD5A1;
}
.AFButtonBorderTopActiveColor:alias {
  color: #64AF8A;
}
.AFButtonGradientEndActiveColor:alias {
  color: #ADE6CA;
}
.AFButtonBorderActiveColor:alias {
  color: #79C39E;
}
```

#### 6.4 Changing an Image for a Component Selector

Many ADF Faces and ADF Data Visualization components reference images using selectors. These images display in the background of the component or render as icons or controls on the component. When you create an ADF skin, the ADF skin that you extend from provides the values for these selectors, such as the relative path to an image and the sizes for height and width.

Figure 6–6 shows a runtime view of the table component rendering a control that sorts the data in a table column in ascending order. The image that renders this control is referenced by the ADF Faces column component's sort-ascending-icon-style selector.

**Figure 6–6 Image Referenced by the sort-ascending-icon-style Selector**

<table>
<thead>
<tr>
<th>Basic table</th>
<th>Export All Rows to Excel</th>
<th>Export Selected Rows to Excel</th>
<th>Print Splitter Content</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Number</strong></td>
<td><strong>Name</strong></td>
<td><strong>Size of the file in kilo</strong></td>
<td><strong>Number</strong></td>
</tr>
<tr>
<td>0</td>
<td></td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td></td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>admin.jar</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>3</td>
<td>applib</td>
<td>0</td>
<td>3</td>
</tr>
</tbody>
</table>

Figure 6–7 shows a design-time view where an ADF skin inherits values for the column component's sort-descending-icon-style selector from the extended ADF skin. The values inherited include the file name for the image used as an icon (colSort_asc_ena.png), the height, and the width for the image.
Other examples of ADF Faces and ADF Data Visualization components that expose selectors which reference images associated with the component include the following:

- ADF Faces `progressIndicator` component exposes the `determinate-empty-icon-style` selector.
- ADF Faces `panelAccordion` component exposes the `disclosed-icon-style` selector.
- ADF Data Visualization `mapToolbar` component exposes the `zoomin-enable-icon` selector.

If you decide that you want to modify the image that is associated with a component selector, you need to modify the selector in your ADF skin and copy the image into the project for your ADF skin. You can copy images individually using the procedure in Section 6.4.1, "How to Copy an Image into the Project."

After you import an image into your project, the selector that references the image uses a URL in the source file of the ADF skin to refer to this image. Note that this URL is updated when you deploy your ADF skin (and associated files) in an ADF Library JAR, as described in Section 11.3, "Packaging an ADF Skin into an ADF Library JAR."

Tip: Associate an image with a global selector alias. If multiple component selectors reference the global selector alias, you only need to make one change if you want to use a different image at a later time (change the image associated with the global selector alias). For more information about global selector aliases, see Section 8.2, "Creating a Global Selector Alias."

If your ADF skin extends the Skyros or Fusion Simple families of ADF skin, you can change some of the more frequently used images in the design editor, as described in Section 6.2, "Changing Images and Colors in the ADF Skin Design Editor." If your ADF skin extends the Fusion Simple family of ADF skins, you can change multiple images using the images editor, as described in Section 6.5, "Working with the Images Editor."

### 6.4.1 How to Copy an Image into the Project

You use a context menu to copy an image that an extended ADF skin references into a directory of the project for your ADF skin. You then make the changes that you want to the image.

**To copy an ADF skin image into your project:**

1. In the Selector Tree of the selectors editor, select the selector that references the image you want to change.
For example, select the ADF Faces column component's sort-descending-icon-style selector to change the sort ascending icon, as shown in Figure 6–8.

Figure 6–8  Column Component's sort-descending-icon-style Selector

2. In the Properties window, expand the Common section and select Copy Image from the Background Image list, as shown in Figure 6–9.

Figure 6–9  Copy Image Menu to Import an Image into ADF Skin Project

This copies the image into the project for your ADF skin.

6.4.2 What Happens When You Copy an Image into the Project

The image is copied into a subdirectory that is generated in the project of your ADF skin. For example, if you decided to copy the image that the ADF Faces column component's sort-ascending-icon-style selector references, the colSort_asc_ena.png file is copied to the following directory:

/public_html/skins/skin1/images/af_column

where af_column refers to the ADF Faces column component.

The relative URL value of the property in the Properties window is modified to reference the new location of the image. Figure 6–10 shows an example.

In addition, the Properties window indicates that the selector no longer inherits the image from the extended ADF skin by displaying a green icon to the left of the property label. Figure 6–10 shows the Properties window after importing the colSort_asc_ena.png file into the project for the ADF skin. Note that the ADF skin still inherits the values for the Height and Width properties from the extended ADF skin.
Finally, CSS syntax appears in the source file of your ADF skin. Example 6-3 shows the CSS syntax that corresponds to the values shown in Figure 6-10.

**Example 6-3  CSS Syntax in Source File of ADF Skin After Importing an Image**

```
af|column::sorted-ascending-icon-style
{
  background-image: url("images/af_column/colSort_des_ena.png");
}
```

### 6.5 Working with the Images Editor

The images editor helps you manage the images that you want to use with an ADF skin that extends from the Fusion Simple family of ADF skins. You access it by clicking the **Images** tab of an open ADF skin.

**Note:** Your ADF skin must extend the Fusion Simple family of ADF skins if you want to use the functionality in the images editor. You cannot use the images editor if you extend your ADF skin from other skin families such as, for example, the Skyros family of ADF skins.

Figure 6-11 shows the images editor that appears when you first click the Images tab in your ADF skin. The **Generate Images Using** dropdown menu displays the following options:

- **Current Skin Aliases**: Select to start with a colorized version using the global selector aliases that appear in the Color category of the current ADF skin. Choosing this option displays the Alias Color list where you can modify the values of these global selector aliases.
- **Desaturated Fusion Simple Colors**: Select to start with a desaturated version of the set of images for the Fusion Simple skin.
- **Fusion Simple Colors**: Select to start with a set of images for the Fusion Simple skin.

**Tip:** Selecting **Desaturated Fusion Simple Colors** from the **Generate Images Using** dropdown menu and clicking **Apply to Skin** is a useful method to retrieve all the current images if you want to modify them manually in another tool.

The Generated Images list displays the available images that you can apply to your ADF skin by clicking the **Apply to Skin** button. When you click the **Apply to Skin**
button, the selected images in the Generated Images list are imported into an images directory that is a subdirectory of the directory in your project where you store your ADF skin.

Figure 6–11 Images Editor for an ADF Skin

The Alias Colors list that appears when you select Current Skin Aliases in the Generate Images Using dropdown menu displays the color aliases that impact the color of layout and icon images. These color aliases are a subset of the available color aliases. Changing the color aliases in this subset can have a significant impact on the appearance of your application. Figure 6–12 shows a page from an application where the parts of a page that use these color aliases are labeled. For example, Bookmarkable Link uses the .AFLightVisitedLinkForeground color alias after a user clicks the link.
Figure 6–13 shows another example where the usage of color aliases is labeled.

For more information about the Color category of global selector aliases, see Section 8.1, "About Global Selector Aliases."

The Oracle Technology Network (OTN) web site provides an online demonstration that shows you how to change the color aliases in the Color Alias list as part of the
process of developing an ADF skin. For more information, navigate to http://www.oracle.com/technetwork/developer-tools/adf/overview/index.html.

6.5.1 How to Generate Images Using the Images Editor

You generate images using the images editor by choosing one of the supported methods and using it to apply changes to your ADF skin.

To generate images using the images editor:

1. Create an ADF skin that extends the Fusion Simple family of ADF skins.
   
   For more information about creating an ADF skin, see Section 4.3, "Creating an ADF Skin File." For more information about the Fusion Simple family of ADF skins, see Section 12.4, "ADF Skins Provided by Oracle ADF."

2. Click the Images tab for the newly-created ADF skin.

3. Choose the method that you want to use to generate the images from the Generate Images Using list.

4. Choose the appropriate option for the image types that you want to include:

   ■ Layout Slices: select this checkbox to include this type of image in your ADF skin.

   ■ Icons: select this checkbox to include this type of image in your ADF skin.

5. (Optional) If you selected Current Skin Aliases from the Generate Images Using dropdown menu, modify the values for the entries in the Alias Color list.

You can do this in a number of ways:

   ■ Enter a Hex code directly in the input field for the global selector alias that you want to modify

   ■ Invoke the Adjust Hue/Saturation/Brightness dialog by clicking Adjust Hue/Saturation/Brightness. This dialog enables you to adjust the hue, saturation and brightness levels of all the colors that your ADF skin uses.

   **Tip:** The changes you make using this dialog apply to all the colors that your ADF skin uses so using this dialog is a quick way to apply a new color hue to your application.

   ■ Invoke a color picker by clicking the dropdown menu beside the input field. You can also invoke the Select Custom Color dialog by clicking the Custom button in the color picker or reset the value of the global selector alias using the Default button. Figure 6–14 shows these buttons and the dropdown menu that initially displays the buttons.
6. (Optional) If you selected Current Skin Aliases from the Generate Images Using dropdown menu, you can click the Exclude Color icon to inhibit the usage of a color alias when you generate images. The Exclude Color icon appears when you move your mouse over a color alias, as shown in Figure 6–15.

Figure 6–14 Editing Options for Color Aliases

6.5.2 What Happens When You Generate Images Using the Images Editor

The image files that you selected in the Generated Images list are imported into the project. Entries appear for each image that you generate in the source file of the ADF skin. Entries also appear for each global selector alias that you modify in the Alias Colors list if you chose to generate the images using the Current Skin Aliases option. Example 6–4 shows some entries that appear in the source file of an ADF skin where images were generated using the Current Skin Aliases option with values modified for the APDarkestNeutralBackground and AFSkyLightBackground global selector aliases.

7. In the Generated Images list, select the images that you want to apply to the ADF skin. Use the checkboxes on the Generated Images list to select or deselect all the images or to select one or more images. By default, the selected images are those that have been modified as a result of changes to the color aliases.

Note: Scroll to the bottom of the Generated Images list to verify that all the images that you want to apply to the skin are selected.

8. Click Apply to Skin.
Providing a Simple Border Style for ADF Skins

You can specify a simple border style for ADF skins that extend the simple skin. This reduces the number of selectors that components, such as the decorativeBox component and panel components (for example, panelBox and panelAccordion), render at runtime and, as a result, simplifies the DOM structure.

This capability is available in Release 11.1.1.7.0 or later and 12.1.2 or later of Oracle ADF. By default, the Skyros skin and ADF skins that extend from Skyros specify a simple border style. If your ADF skin extends from one of the other ADF skins provided by Oracle ADF, as described in Section 12.4, "ADF Skins Provided by Oracle ADF," you need to configure the trinidad-skins.xml file.

You configure the <feature> element of the trinidad-skins.xml file where you register your ADF skin. Example 6–5 demonstrates how to enable a simple border style for the mySkin ADF skin in the trinidad-skins.xml file.

Example 6–5  Enabling a Simple Border Style in the trinidad-skins.xml File

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<skins xmlns="http://myfaces.apache.org/trinidad/skin">
  <skin>
    <id>mySkin.desktop</id>
    <family>mySkin</family>
    <extends>simple.desktop</extends>
    <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
    <style-sheet-name>skins/mySkin/mySkin.css</style-sheet-name>
  </skin>
</skins>
```

6.6 Providing a Simple Border Style for ADF Skins

Example 6–4  Entries in the Source File of an ADF Skin after Generating Images

```css
af|column::sort-descending-icon-style {
   background-image: url("images/generated/META-INF/adf/images/fusion/sort_des_ena.png");
}

af|dvt-map::overview-window-maximize-active-icon {
   content: url("images/generated/bi/images/geoMap/panel_close_dwn.png");
}

.AFDarkestNeutralBackground:alias
{
   background-color: #00ff00;
}
.AFVeryLightBackground:alias
{
   background-color: #00ff00;
}
```
<feature name="BORDER_STYLE">simple</feature>
</features>
</skin>
</skins>
This chapter describes how to work with text in an ADF skin. Key concepts, such as how the resource strings that ADF Faces components render at runtime are stored in resource bundles, are described in addition to how you can specify additional resource bundles with different resource strings.

This chapter includes the following sections:

- Section 7.1, "About Working with Text in an ADF Skin"
- Section 7.2, "Using Text From Your Own Resource Bundle"

### 7.1 About Working with Text in an ADF Skin

The source file for an ADF skin does not store any text that ADF Faces components render in the user interface of your application. Applications that render ADF Faces components abstract the text that these components render as resource strings and store the resource strings in resource bundles. For example, Figure 7–1 shows an ADF Faces dialog component that renders buttons with **OK** and **Cancel** labels.

![ADF Faces dialog Component](image)

The text that appears as the labels for these buttons (**OK** and **Cancel**) is defined in a resource bundle and referenced by a resource string. If you want to change the text that appears in the button labels, you create a resource bundle where you define the values that you want to appear by specifying alternative text for the following resource strings:
In addition to the resource strings that define the text to appear in the user interface for specific components, there are a range of resource strings that define text to appear that is not specific to any particular component. These resource strings are referred to as **global resource strings**. For more information about the resource strings for ADF Faces components and global resource strings, see the Tag Reference for Oracle ADF Faces Skin Selectors (for the release that pertains to the application you are skinning).

ADF Faces components provide automatic translation. The resource bundle used for the ADF Faces components' skin is translated into 28 languages. If, for example, an end user sets the browser to use the German (Germany) language, any text contained within the components automatically displays in German. For this reason, if you create a resource bundle for a new ADF skin, you must also create localized versions of that resource bundle for any other languages your web application supports.

For more information about creating resource bundles, resource strings, and localizing ADF Faces components, see the “Internationalizing and Localizing Pages” chapter in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

### 7.2 Using Text From Your Own Resource Bundle

If you enter alternative text in a resource bundle to override the default text values that render in the user interface of the ADF Faces components in your application, you need to specify this resource bundle for your application. At runtime, the application renders the alternative text in your resource bundle for the resource strings that you override. For resource strings that you do not override, the application renders the text defined in the base resource bundle. For example, Figure 7–4 shows an ADF Faces dialog component where the application developer overrides the default value for the af_dialog.LABEL_OK resource string from OK to **Yay** while the default value for the af_dialog.LABEL_CANCEL resource string remains unchanged. That is, the application developer did not define a value for the af_dialog.LABEL_CANCEL resource string in a resource bundle; the application references the base resource bundle for this resource string’s value.

*Figure 7–2 Overridden and Default Values Resource Strings*

For more information about how to create a resource bundle and how to define string key values, see the "Internationalizing and Localizing Pages" chapter in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).
7.2.1 How to Specify an Additional Resource Bundle for an ADF Skin

You specify a resource bundle for your ADF skin by adding its name and location as a value to the `bundle-name` property in the `trinidad-skins.xml` file.

To specify an additional resource bundle for an ADF skin:

1. In the Applications window, double-click the `trinidad-skins.xml` file for your application. By default, this is under the Web Content/WEB-INF node.

2. In the Structure window, right-click the skin node for which you want to add an additional resource bundle and choose Insert inside skin > bundle-name.

3. In the Properties window, specify the name and location for your resource bundle as a value for the `bundle-name` property.

For example, the resource bundle that is created by default after you create the first ADF skin in your project, as illustrated in Figure 7–3, specifies the following value for the `<bundle-name>` element:

```
<bundle-name>resources.skinBundle</bundle-name>
```

Figure 7–3 Default Resource Bundle for an ADF Skin

7.2.2 What Happens When You Specify an Additional Resource Bundle for an ADF Skin

The `trinidad-skins.xml` file references the resource bundle that you specified as a value for the `bundle-name` property, as shown in Example 7–1.

Example 7–1 Specifying an Additional Resource Bundle in `trinidad-skins.xml`

```
<skin>
    <id>skin1.desktop</id>
    <family>skin1</family>
    <extends>skyros-v1.desktop</extends>
    <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
    <style-sheet-name>skins/skin1/skin1.css</style-sheet-name>
    <bundle-name>resources.skinBundle</bundle-name>
</skin>
```

At runtime, the application renders text values that you specified in your resource bundle to override the default text values. For example, assume that you defined a resource bundle where you specified `Yeah` as the value for the `af_dialog.LABEL_OK` resource string and `Oops` as the value for the `af_dialog.LABEL_CANCEL`. Example 7–4 shows a dialog component that renders labels using these values.
Figure 7–4  Dialog Rendering Labels Defined in a Custom Resource Bundle
This chapter describes how to work with global selector aliases. Information on how to create, modify, and apply a global selector alias is provided in addition to describing how to reference a property value from another selector.

This chapter includes the following sections:

- Section 8.1, "About Global Selector Aliases"
- Section 8.2, "Creating a Global Selector Alias"
- Section 8.3, "Modifying a Global Selector Alias"
- Section 8.4, "Applying a Global Selector Alias"
- Section 8.5, "Referencing a Property Value from Another Selector"

### 8.1 About Global Selector Aliases

A **global selector alias** defines style properties in one location in the ADF skin that you can apply to multiple ADF Faces and ADF Data Visualization components. A global selector alias may also be referred to as a **selector alias**, or simply a **selector**. The ADF skins provided by Oracle ADF, described in Section 1.4, "Inheritance Relationship of the ADF Skins Provided by Oracle ADF" and Section 12.4, "ADF Skins Provided by Oracle ADF" make extensive use of global selector aliases to define common style properties for text, messages, icons, colors and different groups of components. Many component-specific selectors inherit the styles defined for these global selector aliases. For example, the .APDefaultFontFamily:alias global selector alias defines a default font family for all ADF Faces components in your application that display text. Any ADF skin that you create by extending from one of the ADF skins provided by Oracle ADF inherits the properties defined in the .APDefaultFontFamily:alias global selector alias. **Figure 8–1** shows how the selectors editor displays that the af|button selector inherits the value for font family from the .APDefaultFontFamily:alias global selector alias.
Figure 8–1 also shows the different categories of global selector aliases. Each category groups global selector aliases according to their purpose:

- **Color**: Defines colors used by the ADF skins provided by Oracle ADF. Many global selector aliases that you may want to override appear in this category because they determine most of the colors that appear in a Fusion web application. Changes that you make to these global selector aliases have the most effect if you extend the Fusion Simple or Skyros family of ADF skins described in Section 12.4, "ADF Skins Provided by Oracle ADF." In particular, an ADF skin that extends from the Skyros family of ADF skin can have the color palette that it defines changed relatively quickly by changing the global selector aliases that are categorized as anchor colors. For more information, see Section 6.3, "Working with Color in a Skyros-Extended ADF Skin."
Tip: As with other global selector aliases, you can view which component-specific selectors inherit the values defined in a specific global selector using the View as list.

- **Component Group: Button**: Defines style properties inherited by selectors for many of the ADF Faces components that render buttons. For example, the .AFButtonAccessKeyStyle:alias global selector alias defines style properties for the access key rendered by the ADF Faces button and dialog components among others.

- **Component Group: Form Controls**: Defines style properties for form controls.

- **Component Group: Link**: Defines style properties for many of the components that render links.

- **Component Group: PanelBox and Region**: Defines style properties for the panelBox and region components.

- **Component Group: Tabs**: Defines style properties for many of the ADF Faces components that render tabs. For example, the .AFFormAccessKeyStyle:alias global selector alias defines the style properties for access keys that render in the ADF Faces panelTabbed and navigationPane components.

- **Font**: Defines style properties for fonts. For example, the .AFDefaultFontFamily:alias global selector alias defines the style properties inherited by many of the ADF Faces component selectors.

- **Icons**: Defines the style properties that apply to icons that render in multiple components.

- **Message Selectors**: Defines style properties for messages that ADF Faces input components display when they render different types of messages. For more information, see Section 5.5, "Configuring ADF Skin Properties to Apply to Messages."

- **Miscellaneous**: Defines global selector aliases that do not fit in the other categories. For example, the .AFDynamicHelpIconStyle:alias global selector alias defines the style to use for the dynamic help icon.

- **Text**: Defines style properties to use for text.

For detailed descriptions of the global selector aliases, see the *Tag Reference for Oracle ADF Faces Skin Selectors* (for the release that pertains to the application you are skinning). Global selector aliases that you define appear under the Global Selector Aliases node, as shown by the entry for the .UserDefined:alias in Figure 8–1.

The View as list displays the list of components that reference a global selector alias when you select a global selector alias in the Selector Tree. In Figure 8–2, the user selected Panel Window from the list because the panelWindow component references the global selector alias.
About Global Selector Aliases

Note: Sometimes components appear in the View as list for which the style properties defined in the global selector alias do not render in the component. This may be because the component initially referenced the global selector alias in an extended ADF skin and your ADF skin overrides the global selector alias for that component. Alternatively, it may be because the component itself overrides the global selector alias using one of its style-related attributes (styleClass or inlineStyle).

In Figure 8–2, the user has changed the inherited value for the .AFDefaultFontFamily:alias global selector alias and viewed the resulting change as it applies to the panelWindow component. All selectors that inherit the value of the .AFDefaultFontFamily:alias global selector alias will render at runtime using the font family defined in the ADF skin. For example, both the dialog and panelWindow components render using this font family.

Figure 8–2 ADF Skin Changing a Global Selector Alias

In addition to the global selector aliases already described, a number of component selectors define selector aliases that are specific to these components only. These selector aliases appear under the nodes for the component selectors in the Selector Tree. Figure 8–3 shows examples from a number of the component selectors that expose these types of selector aliases.
8.2 Creating a Global Selector Alias

You can create a global selector alias to define in one location the style properties that you want a number of selectors to reference. You enter the name of the new global selector alias in the Create Alias Selector dialog. The ADF Skin Editor appends the keyword :alias and prepends . to the name that you enter in the dialog. For example, if you enter myGlobalSelector as the name in the dialog, the resulting name that appears in the user interface and in the source file of the ADF skin is:

.myGlobalSelector:alias

The keyword :alias identifies your global selector alias as a CSS pseudo-class and serves as a syntax aid to organize the CSS code in the source file of your ADF skin.

After you create a global selector alias, you modify it to define the style properties that you want it to contain. For more information, see Section 8.3, "Modifying a Global Selector Alias."

8.2.1 How to Create a Global Selector Alias

You can create a global selector alias that defines the style properties that you want a number of user interface components to use.

To create a global selector alias:

1. In the Selector Tree of the selectors editor, select New Alias Selector from the dropdown list, as illustrated in Figure 8–4.

2. Enter a name for the global selector alias in the Alias Selector Name field.
8.2.2 What Happens When You Create a Global Selector Alias

The global selector alias appears under the Global Selector Aliases node in the Selector Tree and a visual representation as it applies to a component appears in the Preview Pane, as illustrated in Figure 8–5.

Figure 8–5 Newly-Created Global Selector Alias

CSS syntax for the global selector alias that you create appears in the source file of the ADF skin. Example 8–1 shows the entries that appear in the source file of the ADF skin in Figure 8–5.

Example 8–1 CSS Syntax for a Newly-Created Global Selector Alias

```
.MyLinkHoverColor:alias
{
}
```

8.3 Modifying a Global Selector Alias

You can modify any of the categories of global selector alias described in Section 8.1, "About Global Selector Aliases." Modifying a global selector alias that appears under the Global Selector Aliases node in the Selector Tree when you first create the ADF skin means that you override the inherited style properties defined in the parent ADF skin of your ADF skin. The parent ADF skin is the ADF skin from which your ADF skin extends. You chose the ADF skin from which to extend when you created an ADF skin, as described in Section 4.3, "Creating an ADF Skin File." After you modify a global selector alias, the component-specific selectors that inherit the style properties defined in the global selector alias use the modified values.
Modifying a global selector alias that you create in your ADF skin does not override any style properties inherited from the parent ADF skin.

### 8.3.1 How to Modify a Global Selector Alias

You modify a global selector alias by setting values for it in the Properties window. You then verify that the changes you make apply to the component-specific selectors as you intend.

**To modify a global selector alias:**

1. In the Selector Tree of the selectors editor, select the global selector alias that you want to modify.

   For example, if you want to modify the global selector alias that defines the default font family, select it as illustrated in Figure 8–6.

   ![Figure 8–6 Modifying a Global Selector Alias](image)

2. In the Properties window, set values for the properties that you want to modify.

3. In the selectors editor, click the View as list to select a component-specific selector that inherits the property values defined in the global selector alias that you have just modified.

4. In the selectors editor, verify that the changes render for the component-specific selector as you intend. Repeat Steps 1 to 3 until you achieve the changes you want for the component-specific selectors that inherit from the global selector alias.

### 8.4 Applying a Global Selector Alias

After you create a global selector alias in your ADF skin, you need to specify the ADF Faces and ADF Data Visualization components that you want to render at runtime using the style properties that you defined in the global selector alias.

Applying a global selector alias to an ADF Faces or ADF Data Visualization component requires you to:

- Select the selector, pseudo-element, or pseudo-class for each component that you want to apply the style properties defined in the global selector alias. If you want
to apply the style properties defined in your global selector alias to another global selector alias, select the target global selector alias.

- Set the global selector alias as a value for the `-tr-rule-ref-` ADF skin property.

### 8.4.1 How to Apply a Global Selector Alias

You apply a global selector alias by specifying it as a value for the `-tr-rule-ref-` ADF skin property.

**To apply a global selector alias:**

1. In the Selector Tree of the selectors editor, select the item to which you want to apply the global selector alias.
   
   For example, select the `inputText` component's `content` pseudo-element if you want to apply the style properties defined in your global selector alias to the label for that component, as shown in Figure 8–7.

2. In the Properties window, expand the `Common` section and then click the Add icon next to the `-tr-rule-ref-` field.

3. Enter the name of the global selector alias. Enter the name between quotes that you preface with the `selector` keyword in the `Value` field.
   
   For example, if the name of the global selector alias is `.MyBackgroundColor:alias`, enter `selector(".MyBackgroundColor:alias")`, as illustrated in Figure 8–7.

   **Figure 8–7  inputText Component's content Pseudo-Element**

4. Click the Refresh icon in the Preview Pane to view the changes.

### 8.4.2 What Happens When You Apply a Global Selector Alias

The selector to which you applied the global selector alias inherits the style properties defined in the global selector alias. Figure 8–8 shows the `content` pseudo-element for the `inputText` component's selector that inherits the style properties defined in the `.MyBackgroundColor:alias` global selector alias. The properties that inherit their values from a global selector alias when you specify the global selector alias as a value for the `-tr-rule-ref-` ADF skin property update to use the inheritance icon, as shown for the `Background Color` and `Color` fields in Figure 8–8.

At runtime, the `inputText` component's content area renders using the style properties defined in the global selector alias.
8.4.3 What You May Need to Know About Applying a Global Selector Alias

If you override a global selector alias in an extended ADF skin, component selectors that used the -tr-rule-ref ADF skin property to determine the value of a style property in the parent ADF skin use the overridden value of the global selector alias. **Example 8–2** shows ADF skin B that extends ADF skin A. At runtime, the top of a decorativeBox component renders red for the background-color CSS property because the global selector alias in ADF skin B overrides ADF skin A.

**Example 8–2  Overriding an Inherited Global Selector Alias**

```html
/** Skin A **/
/** ---------------------------------- **/
.MyBackColor:alias
{
  background-color: blue
}

af|decorativeBox::top
{
  -tr-rule-ref: selector(".MyBackColor:alias");
}

/** Skin B **/
/** ---------------------------------- **/
.MyBackColor:alias
{
  background-color: Red
}
```

If you specify a style property value in an extended ADF skin where the parent ADF skin also specifies a value for the style property, the ADF skinning framework applies the value in the extended ADF skin. **Example 8–3** shows ADF skin C where the .myClass style class specifies Red as the value for the background-color CSS property.
property. If an application uses ADF skin D (that extends ADF skin C), components that apply the .myClass style class apply Lime for the background-color CSS property. This is because the ADF skinning framework calculates the values of statements that include values in an ADF skin (like -tr-rule-ref) first. The ADF skinning framework then calculates specific properties (for example, background-color) next. As a result, the value for the background-color CSS property in ADF skin D (Lime) overrides the value for the -tr-rule-ref ADF skin property (Blue) or inherited values from ADF skin C (Red).

**Note:** If you subsequently override the .myClass style class as follows in ADF skin D, the value that the ADF skinning framework applies for the background-color CSS property is Blue:

```
.myClass {-tr-rule-ref: selector(".MyBlueColor:alias")}
```

---

**Example 8–3 Overriding a Local Global Selector Alias**

```*/* ADF skin C */*/
/* ----------------------------- */
.myClass {
  background-color: Red
}

/* ADF skin D */*/
/* ----------------------------- */
.MyBackColor:alias {
  background-color: Blue;
}

.myClass {
  background-color: Lime;
  -tr-rule-ref: selector(".MyBackColor:alias")
}
```

Consider using tools, such as Firebug for the Mozilla Firefox browser (or similar for your browser), when you run your application to determine what style property value the ADF skinning framework applies to a component selector at runtime. For more information, see Section 11.2, “Testing Changes in Your ADF Skin.”

### 8.5 Referencing a Property Value from Another Selector

Rather than set a specific style property for each selector to which you want to apply the style property, you can reference the value of a property using the -tr-property-ref ADF skin property. You can configure this ADF skin property for global selector aliases and component-specific selectors. For example, you could define a value for the background-color property in a global selector alias and reference this value from multiple other selectors. If you decide at a later time to change the value of the background-color property, you change the value in the global selector alias. All selectors that reference the background-color property using the -tr-property-ref ADF skin property update to use the change you make. The -tr-property-ref ADF skin property can also be used with compact CSS properties like, for example, border.
8.5.1 How to Reference a Property Value from Another Selector

You reference the property value that you want to use for a selector using the -tr-property-ref ADF skin property.

To reference a property value from another selector:

1. In the Selector Tree of the selectors editor, select the selector that you want to reference a property value from another selector.

   For example, if you want the content area of the panelWindow component to reference a style property defined in another selector, select content under the Pseudo-Elements node of the panelWindow component, as illustrated in Figure 8–9.

   **Figure 8–9  Panel Window Component’s content Pseudo-Element**

2. In the Properties window, specify the property value that you want to reference as a value for the selector’s property using the -tr-property-ref ADF skin property.

   For example, assume that you created the following global selector alias:

   ```css
   .MyColor:alias {
     color: rgb(255,181,99);
     font-weight: bold;
   }
   ```

   and that you want to reference the color property from this global selector alias for the background-color property of the content pseudo-element that you selected in Step 1. In this scenario, enter the following value for the background-color property of the content pseudo-element,

   `-tr-property-ref(".MyColor:alias", ‘color’);

   If you want to use the -tr-property-ref in compact values, enter syntax similar to the following:

   ```css
   border: 10px solid -tr-property-ref(".AFDefaultColor:alias", ‘color’);
   ```

8.5.2 What Happens When You Reference a Property Value from Another Selector

The Properties window shows that the property for which you set a value using the -tr-property-ref ADF skin property to reference a value from another selector inherits its value, as illustrated in Figure 8–10.
Referencing a Property Value from Another Selector

Figure 8-10  Selector Property Referencing a Property Value from Another Selector

Syntax similar to Example 8-4 appears in the source file of the ADF skin.

**Example 8-4  -tr-property-ref ADF Skin Property**

```html
@charset "UTF-8";
/**ADFFaces_Skin_File / DO NOT REMOVE**/
@namespace af "http://xmlns.oracle.com/adf/faces/rich";
@namespace dvt "http://xmlns.oracle.com/dss/adf/faces";

.MyColor:alias {
  color: rgb(255, 181, 99);
  font-weight: bold;
}

.AFDefaultColor:alias {
  color: Red;
}

af|panelWindow::content {
  background-color: -tr-property-ref(".MyColor:alias", "color");
  border: 10px solid -tr-property-ref(".AFDefaultColor:alias", "color");
}
```
Referencing a Property Value from Another Selector
This chapter describes how to work with style classes. Information on how to create, modify, and apply a style class is provided in addition to describing how to configure a style class for a specific instance of a component.

This chapter includes the following sections:

- Section 9.1, "About Style Classes"
- Section 9.2, "Creating a Style Class"
- Section 9.3, "Modifying a Style Class"
- Section 9.4, "Configuring a Style Class for a Specific Instance of a Component"

9.1 About Style Classes

A style class allows you to specify a number of style properties in one location in an ADF skin that you want to apply to specific instances of ADF Faces or ADF Data Visualization components. The style properties that you define for a style class take precedence over the style properties that you define for the component's selectors. Application developers can specify a style class as a value for the `styleClass` and `inlineStyle` attributes that many ADF Faces components expose. At runtime, the style properties that you defined in the style class get applied to the ADF Faces component rather than other style properties defined in the ADF skin. Style classes differ from the global selector aliases, described in Chapter 8, "Working With Global Selector Aliases," which enable you to define style properties that you want to apply to multiple ADF Faces components.

Figure 9–1 shows an ADF skin with the nodes expanded for the different categories of style classes.

Figure 9–1 Categories of Style Class

![Figure 9–1 Categories of Style Class](image)
Each category of style class serves a purpose:

- **Miscellaneous**: Miscellaneous style classes inherited from the extended ADF skins. For example, this category includes the .AFBrandingBar style class that can be used for a branding bar containers.

- **Note Window Selectors**: Style classes inherited from the extended ADF skins that affect the noteWindow component.

- **Popup**: Style classes inherited from the extended ADF skins that affect the popup component.

- **Text**: Style classes inherited from the extended ADF skins that determine the appearance of various types of text (for example, address fields and instruction text).

Style classes that you or other users define appear under the Style Classes node as shown by the entry for the .UserDefined style class in Figure 9–1. For detailed descriptions of the style classes in the ADF skins that Oracle ADF provides, see the Tag Reference for Oracle ADF Faces Skin Selectors (for the release that pertains to the application you are skinning).

### 9.2 Creating a Style Class

You can create a new style class in your ADF skin or override a style class that your ADF skin inherits from the ADF skin that it extends.

After you create a style class, you modify it to define the style properties that you want it to contain. For more information, see Section 9.3, "Modifying a Style Class."

#### 9.2.1 How to Create a Style Class

You can create a style class that defines the style properties you want an application developer to apply to an ADF Faces or ADF Data Visualization component using the component's styleClass or inlineStyle attribute.

**To create a style class:**

1. In the Selector Tree of the selectors editor, select **New Style Class** from the dropdown list, as shown in Figure 9–2.

   **Figure 9–2 New Style Class Option in the Selector Tree**

   The Create Style Class dialog opens.

2. Choose the appropriate option:

   - Enter a new name if you want to create a new style class that does not inherit style properties from an ADF skin that your ADF skin extends.

   **Tip:** Enter a name for the style class that indicates the purpose it serves.
Enter the name of a style class that inherits style properties from an ADF skin that your ADF skin extends and for which you want to override style properties in your ADF skin.

3. Click OK.

9.2.2 What Happens When You Create a Style Class

The style class appears under the Style Classes node in the Selector Tree and a visual representation as it applies to a component appears in the Preview Pane, as shown in Figure 9–3.

Figure 9–3 Newly-Created Style Class

CSS syntax for the style class that you create appears in the source file of the ADF skin. Example 9–1 shows the entries that appear in the source file for the ADF skin in Figure 9–3.

Example 9–1 CSS Syntax for a Newly-Created Style Class

```
.OrderOverdue
{
}
```

9.3 Modifying a Style Class

The process to modify a style class is the same for the different categories of style class that appear in the selectors editor. You select the style class in the Selector Tree and use the menus in the Preview Pane to add or remove pseudo-classes to the style class or use the Properties window to set or override style properties for the style class.

9.3.1 How to Modify a Style Class

You select the style class under the Style Classes node in the Selector Tree and modify its properties using the Properties window.

To modify a style class:

1. In the Selector Tree, navigate to the style class that you want to modify.
2. In the Properties window, make changes to the properties that you want to configure for the style class.
3. Click the Refresh icon to update the Preview Pane after you make changes to the style class.
9.4 Configuring a Style Class for a Specific Instance of a Component

You can define a style class where you define style properties to apply to a specific instance of a component. Consider, for example, a panelBox component that application developers use to show or hide content on a page. One page can render multiple instances of a panelBox component. You decide to make fuchsia the default background color for the header text that panelBox components render, as shown in Figure 9–4.

![Figure 9–4 Setting Background Color for a panelBox Component](image)

However, you decide that you want to render one or more instances of the panelBox component without the disclosure link control that allows end users to show and hide the content in the component. Additionally, you decide that you want the header text of these instances of the panelBox component to render with the background color set to red. To achieve this, you define style properties for a style class in the ADF skin. You then specify the style class as the value for the styleClass attribute for each instance of the panelBox component that you want to render using these style properties. Example 9–2 shows the syntax that appears in the source file of the ADF skin to achieve the outcome just described.

### Example 9–2 Syntax for a Style Class in an ADF Skin

```
.panelBoxInstanceClass af|panelBox::disclosure-link{display:none;}
.panelBoxInstanceClass af|panelBox::header-text {background-color: Red;}
```

### 9.4.1 How to Configure a Style Class for a Specific Instance of a Component

You specify the style class as the value for the styleClass attribute for each instance of a component that you want to render using the style class.

**To configure a style class for a specific instance of a component:**

1. Create a style class, as described in Section 9.2, "Creating a Style Class."
2. In JDeveloper, set the component's styleClass attribute to the name of the style class you created in step 1.

For more information about setting the component's styleClass attribute, see Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).
9.4.2 What Happens When You Configure a Style Class for a Specific Instance of a Component

At runtime, instances of the component for which you do not specify instance-specific style properties using a style class render using the style properties defined in the component-specific selectors and global selector aliases. In Figure 9–5, this is the panelBox component labeled First Panel Box. Instances of the component for which you specify a style class as a value for the styleClass attribute render using the style properties defined in this style class. In Figure 9–5, this is the panelBox component labeled Second Panel Box.

Figure 9–5 Component Rendering with Style Properties Defined in Style Class

First Panel Box

Second Panel Box
This chapter describes how to work with at-rules. Information on how to create, modify, and apply an at-rule is provided in addition to describing the various types of at-rule that the ADF skinning framework defines.

This chapter includes the following sections:

- Section 10.1, "About At-Rules"
- Section 10.2, "Creating an At-Rule"

10.1 About At-Rules

CSS at-rules (at-rules) are a way to define style properties for when an application's page renders in a particular environment such as, for example, a browser, platform, or locale. The ADF skinning framework defines a number of at-rules that allow you to define properties for selectors that you want to apply to a particular environment.

For example, you may need to add some padding in Internet Explorer that you do not need on any other browser or maybe you want a font style to be different on a Linux platform than it is on other platforms. To style a selector for a particular user environment, put that skinning information inside an at-rule.

The selectors editor in the ADF Skin Editor and in JDeveloper supports the creation of at-rules in your ADF skin, as described in Section 10.2, "Creating an At-Rule." At-rules defined in the ADF skins that your ADF skin extends or at-rules that you define in your ADF skin appear in the Selector Tree under the At-Rules node, as illustrated in Figure 10–4
Apart from the at-rules described in this chapter, you can also use the `@import` at-rule to import another ADF skin into your ADF skin. For more information, see Section 4.4, "Importing One or More ADF Skins Into the Current ADF Skin."

### 10.2 Creating an At-Rule

You can create a new at-rule in your ADF skin or override an at-rule that your ADF skin inherits from the ADF skin that it extends. After you create an at-rule, you modify it to define the style properties that you want it to contain.

Table 10–1 lists a number of the at-rules that the ADF skinning framework supports. Apart from the rules listed in Table 10–1, one of the most frequently used at-rules is the `@agent` at-rule that enables you to define styles to apply to one or more browsers.

The supported values to set a browser agent-specific style are:

- `blackberry`
- `email`
- `gecko`
- `genericDesktop`
- `genericpda`
- `googlebot`
- `ie`
- `konqueror`
- `mozilla`
- `msnbot`
- `nokia_s60`
- `opera`
Creating an At-Rule

Using the @agent at-rule, you can:

- Specify styles for any version of Internet Explorer:
  
  ```
  @agent ie
  ```

  Optionally, specify a specific version of the agent using the and keyword. For example, to specify version 9 of Internet Explorer:

  ```
  @agent ie and (version: 9)
  ```

- Use comma-separated rules to specify styles for a number of agents. For example, use the following rule to specify styles for Internet Explorer 8.x, Internet Explorer 9.x, or Gecko 1.9:

  ```
  @agent ie and (version: 8), ie and (version: 9), gecko and (version: 1.9)
  ```

- Note that the following two syntax examples specify the same rule:

  ```
  @agent ie and (version: 8.*)
  @agent ie and (version: 8)
  ```

  To specify a rule for styles to apply only to Internet Explorer 8.0.x, write the following:

  ```
  @agent ie and (version: 8.0.x)
  ```

- Use the max-version and min-version keywords to specify a range of versions. For example, you can rewrite the following rule:

  ```
  @agent ie and (version: 8), ie and (version: 9)
  ```

  as:

  ```
  @agent ie and (min-version: 8) and (max-version: 9)
  ```

  to apply styles that you define to all versions of Internet Explorer 8 and 9.

You can also use the @agent rule to determine styles to apply to agents that are touch devices. The following examples show the syntax that you write in an ADF skin file to configure this capability.

```java
@agent (touchScreen) {
    /* Touchscreen specific styles for all touch devices: both single and multiple touch. */
}
```

```java
@agent (touchScreen:single) {
    /* Styles specific for a touch device with single touch. */
}
```

```java
@agent (touchScreen:multiple) {
    /* Styles specific for a touch device with multiple touch. */
}
```

Use the @agent (touchScreen:none) at-rule to specify styles that you do not want to render on a touch device. For example, the Fusion Simple family of ADF skin (fusionFx-simple-v1.2 and later) applies this at-rule to selectors configured to use the :hover pseudo-class. This is because the :hover pseudo-class is not
appropriate for use on a touch device. The `@agent (touchScreen:none)` at-rule wraps selectors that use the `:hover` pseudo-class, as in the following example:

```css
@agent (touchScreen:none){
  af|breadCrumbs:step:hover{
    text-decoration:underline;
  }
}
```

Figure 10–2 shows how the Selector Tree displays selectors to which the `@agent (touchScreen:none)` at-rule is applied.

For more information about creating applications to render in touch devices, see the "Creating Web Applications for Touch Devices Using ADF Faces" appendix in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).
10.2.1 How to Create an At-Rule

You can create an at-rule to specify that style properties for one or more selectors render in a particular way when a condition specified by the at-rule is met.

**To create an at-rule:**

1. In the Selector Tree of the selectors editor, select New Selector with At-Rule from the dropdown list, as illustrated in Figure 10–3.

**Tip:** If you know the name of the selector for which you want to configure an at-rule, right-click it in the Selector Tree and, from the context menu, choose New Selector with At-Rule. This populates the Selector field in the Create At-Rule Declaration dialog with the name of the selector that you right-clicked.

Table 10–1  At-Rules for ADF Skins

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| @accessibility-profile | Defines styles for high-contrast and large-fonts accessibility profile settings when enabled in the trinidad-config.xml file.  
For more information about the @accessibility-profile rule, see Section 5.7, "Configuring an ADF Skin for Accessibility.” |
| @locale            | Specify a locale to define styles only for a particular language and country. You can specify either only the language or both the language and the country.  
Example 10–1 demonstrates how you can set the color of text rendered by the af:commandMenuItem component on a menu bar when the locale is German (de).  
Note that the ADF skinning framework does not support the :lang pseudo class. |
| @mode              | Defines styles for when a page renders in a particular mode. This at-rule supports the following values:  
- quirks  
- standards |
| @platform          | Define platform styles. Supported values are:  
- android  
- blackberry  
- genericpda  
- iphone  
- linux  
- macos  
- nokia_s60  
- ppc (Pocket PC)  
- solaris  
- unix  
- windows |

Figure 10–3  New Selector with At-Rule Menu in the Selector Tree
2. In the Create At-Rule Declaration dialog, select the at-rule that you want to configure from the Rule dropdown list.

For more information about the supported at-rules, see Section 10.2, "Creating an At-Rule."

3. Click OK.

4. In the Selector Tree, select the newly-created at-rule and, in the Properties window, configure the properties that you want this at-rule to apply.

10.2.2 What Happens When You Create an At-Rule

The at-rule appears under the At-Rules node in the Selector Tree and a visual representation as it applies to a component appears in the Preview Pane, as shown in Figure 10–4. CSS syntax for the at-rule that you create and any properties that you modified also appear in the source file of the ADF skin, as shown in Figure 10–4.

Figure 10–4  At-Rule in the Selector Tree and Source Editor

In the Properties window for the selector property on which you set an at-rule, an icon appears to indicate that an at-rule is set, as illustrated in Figure 10–5.
10.2.3 What You May Need to Know About At-Rules

At runtime, the ADF skinning framework picks the styles with at-rules based on the HTTP request information, such as agent and platform, and merges them with the styles without rules. Those style properties that match the rules get merged with those outside of any rules. The most specific rules that match a user’s environment take precedence.

Example 10–1 shows several selectors in the source file of an ADF skin that will be merged together to provide the final style.

Example 10–1  Merging of Style Selectors in an ADF Skin

```/** For IE and Gecko on Windows, Linux and Solaris, make the color pink. **/ @platform windows,linux,solaris{ @agent ie, gecko
  { af|inputText::content {background-color:pink}
    }
}

/** Define default properties for the af|panelFormLayout selector. **/
af|panelFormLayout {
  color: red;
  width: 10px;
  padding: 4px
}

/** Define at-rule for af|panelFormLayout on Internet Explorer (IE). We need to increase the width, so we override the width. We still want the color and padding; this gets merged in. We want to add height in IE. */ @agent ie{
  af|panelFormLayout {width: 25px; height: 10px}
}

/** For IE 8 and 9, we also need some margins.*/ @agent ie{ version:8}and{ version:9} {
  af|panelFormLayout {margin: 5px;}
}

/** For Firefox 3 (Gecko 1.9) use a smaller margin.*/ @agent gecko{ version:1.9}{
```
af|panelFormLayout {margin: 4px;}
}

10-8  Creating ADF Skins with Oracle ADF Skin Editor
Applying the Finished ADF Skin to Your Web Application

This chapter describes how to complete tasks that you need to do once you finish your ADF skin. Information is provided on how to test your ADF skin, package the completed ADF skin in an ADF Library JAR, and configure an ADF application so that it uses the completed ADF skin.

This chapter includes the following sections:

- Section 11.1, "About Applying a Finalized ADF Skin to an Application"
- Section 11.2, "Testing Changes in Your ADF Skin"
- Section 11.3, "Packaging an ADF Skin into an ADF Library JAR"
- Section 11.4, "Applying an ADF Skin to Your Web Application"
- Section 11.5, "Applying an ADF Skin to a Running Web Application"

11.1 About Applying a Finalized ADF Skin to an Application

After you create an ADF skin where you define style properties for one or more ADF skin selectors, you may want to test the changes that you make in the ADF skin. Once you complete testing the changes in your ADF skin and are satisfied with the final ADF skin, you can package the ADF skin and associated files (images, resource bundles, and configuration files) into an ADF Library JAR to distribute for inclusion to the application projects that use the final ADF skin. Once you have distributed the final ADF skin, you configure the application to apply the ADF skin to it.

11.2 Testing Changes in Your ADF Skin

Once you have created an ADF skin and defined style properties that you want for one or more selectors, you may want to test how these style properties render at runtime in a browser. To do this, you apply the ADF skin to your application and run a page that renders the ADF Faces component which exposed the selector.

Consider using tools, such as Firebug for the Mozilla Firefox browser (or similar for your particular browser), when you run your application. These tools provide useful information that can help you as you iteratively develop your ADF skin. For example, in addition to inspecting changes that you have already made, these tools can help you identify the ADF skin selectors that correspond to a particular DOM element.

You can also configure context initialization parameters in the web.xml file of your application that allow you to:

- View changes in an ADF skin without having to restart the application
Testing Changes in Your ADF Skin

Set the value of the following context initialization parameter to true:

```
org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION
```

- Display the full uncompressed CSS style class name at runtime
  
  Set the value of the following context initialization parameter to true:

  ``
  org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION
  ```

Note that not all changes that you make to an ADF skin in your Fusion web application appear immediately if you set the CHECK_FILE_MODIFICATION to true. You must restart the Fusion web application to view changes that you make to icon and ADF skin properties.

For more information about context initialization parameters, see the "ADF Faces Configuration" appendix in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).

Figure 11–1 demonstrates how the name of a component selector (for the ADF Faces button component) is suppressed. In Figure 11–1, the style class (fndGlobalSearchCategory) that is defined in an ADF skin is applied to the button component using the component's styleClass attribute.

**Figure 11–1 Compressed CSS from an ADF Skin**

![Compressed CSS from an ADF Skin](image1.png)

Figure 11–2 shows how the browser renders the full uncompressed name of the ADF Faces component when you set the DISABLECONTENT_COMPRESSION parameter to true. In Figure 11–2, the uncompressed style class af_button corresponds to the af|button selector documented in the Tag Reference for Oracle ADF Faces Skin Selectors (for the release that pertains to the application you are skinning).

![Uncompressed CSS from an ADF Skin](image2.png)
The uncompressed style classes that correspond to the pseudo-elements that an ADF skin selector exposes can also be identified. For example, the `tab-end` pseudo-element exposed by the `af|panelTabbed` selector translates to the uncompressed `af_panelTabbed_tab-end` style class at runtime.

Similarly, changes that you make to the appearance of a component when it is in a specific state can also be identified or inspected using browser tools. For example, the following entry in the source file of an ADF skin allows you to define the style for the ADF Faces `panelTabbed` component when a user selects the right-hand side of the component:

```css
af|panelTabbed::tab:selected af|panelTabbed::tab-end
```

At runtime, the uncompressed style class name translates to the following:

```css
.af_panelTabbed_tab.p_AFSelected .af_panelTabbed_tab-end
```

Note that `:selected` translates to `p_AFSelected` although sometimes the generated CSS does not have a `p_AFSelected` equivalent because some browsers have built-in support for that particular state, as is the case for other pseudo-classes like `:hover`.

It is recommended that you only customize the ADF skin selectors, pseudo-elements, and pseudo-classes documented in the Tag Reference for Oracle ADF Faces Skin Selectors and the Tag Reference for Oracle ADF Data Visualization Tools Skin Selectors (for the release that pertains to the application you are skinning). Customizing other ADF skin selectors may result in unexpected or inconsistent behavior for your application.
Testing Changes in Your ADF Skin

11.2.1 How to Set Parameters for Testing Your ADF Skin
You set the \texttt{CHECK\_FILE\_MODIFICATION} and \texttt{DISABLE\_CONTENT\_COMPRESSION} context initialization parameters to \texttt{true} in the \texttt{web.xml} file of your application.

To set parameters for testing your ADF skin:
1. In the Applications window, double-click the \texttt{web.xml} file.
2. In the source editor, add the following context initialization parameter entries and set to \texttt{true}:
   - \texttt{org.apache.myfaces.trinidad.CHECK\_FILE\_MODIFICATION}
   - \texttt{org.apache.myfaces.trinidad.DISABLE\_CONTENT\_COMPRESSION}
3. Save and close the \texttt{web.xml} file.

11.2.2 What Happens When You Set Parameter for Testing Your ADF Skin
Entries appear in the \texttt{web.xml} file for your application, as illustrated in Example 11–1.

\texttt{Example 11–1 web.xml Entry}

\begin{verbatim}
<context-param>
  <param-name>org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION</param-name>
  <param-value>true</param-value>
</context-param>
\end{verbatim}
Changes that you make to a selector for an ADF Faces component (other than changes to icon and skin properties) render immediately when you refresh a Fusion web application's page that renders the ADF Faces component. Using Firebug if your browser is Mozilla Firefox or Google Chrome's developer tools, you can see the uncompressed style class names that render at runtime and establish what ADF skin selector it corresponds to. Remember that setting org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION to true incurs a performance cost for your Fusion web application so set it to false when you finish testing your changes.

11.3 Packaging an ADF Skin into an ADF Library JAR

You can deploy an ADF skin and associated files (for example, image files, configuration files, and resource bundles) in an ADF Library JAR. This enables you to package files required to apply an ADF skin to an application. The benefits of packaging ADF skins into an ADF Library JAR as compared to bundling them into the application are the following:

- An ADF skin can be deployed and developed separately from the application. This also helps to reduce the number of files to be checked in case some changes must be applied to the ADF skin.

- The source files for an ADF skin and images can be separated into their own ADF Library JARs. Therefore, you can partition the image base into separate ADF Library JARs, so that not all files have to be deployed with all applications.

- An ADF skin in an ADF Library JAR can be applied to an application that is running without requiring a restart, as described in Section 11.5, "Applying an ADF Skin to a Running Web Application."

11.3.1 How to Package an ADF Skin into an ADF Library JAR

Create an ADF Library JAR file deployment profile to package the ADF skin into an ADF Library JAR.

To create an ADF Library JAR file deployment profile:

1. In the Applications window, right-click the project that contains the ADF skins and choose Deploy > New Deployment Profile.

2. In the Create Deployment Profile dialog, choose ADF Library JAR File in the Profile Type dropdown list.

3. Enter a name for the deployment profile in the Deployment Profile Name input field and click OK.

4. Review the options in the Edit ADF Library JAR Deployment Profile Properties dialog that appears. For more information at any time, click Help.

5. Click OK.
To package an ADF skin into an ADF Library JAR:

1. In the Applications window, right-click the project that contains the ADF skin and choose **Deploy > deployment**, where *deployment* is the name of the ADF Library JAR file deployment profile.

2. In the Deploy dialog Deployment Action page, click **Deploy to ADF Library JAR file**, click **Next** and then click **Finish**.

### 11.3.2 What Happens When You Package an ADF Skin into an ADF Library JAR

An ADF Library JAR file is written to the directory specified by the deployment profile. This ADF Library JAR contains the source file for the ADF skin, the *trinidad-skins.xml* file, image files, and any resource bundles that you created to define resource strings or to override the default strings defined for ADF Faces components. The ADF Library JAR file also contains other files from the ADF skin’s project not related to skinning.

**Example 11–2** shows the directory structure for a project that contains the following items for an ADF skin:

- The *trinidad-skins.xml* file
- An image file (*sort_des_ena.png*) copied into the ADF skin project
- The source file for an ADF skin (*skin1.css*)
- An *.sva* file (*oracle.adf.common.services.ResourceService.sva*) that is used to inspect the content of the ADF Library JAR when you import it into a project, as described in Section 4.5, "Importing ADF Skins from an ADF Library JAR."
- A resource bundle (*skinBundle.properties*) that contains string values to override strings from the default resource bundle

For information about how to specify resource bundles that contain string values you define, see Section 7.2.1, "How to Specify an Additional Resource Bundle for an ADF Skin."

**Example 11–2 Directory Structure for an ADF Library JAR Containing an ADF Skin**

```
ADFLibraryJARRootDirectory
    +---META-INF
    |   |   MANIFEST.MF
    |   |   oracle.adf.common.services.ResourceService.sva
    |   |   trinidad-skins.xml
    |   |
    |   +---adf
    |       |---skins
    |       |   |---skin1
    |       |   |   |---images
    |       |   |   |   |---af_column
    |       |   |   |   |   |---colSort_des_ena.png
    |       |   |---skins
    |       |   |---skin1
    |       |       |---skin1.css
    |
    +---resources
        |---skinBundle.properties
```
The directory paths for images in the ADF skin that appear in the ADF Library JAR are modified to include the directory path from the ADF skin project. Example 11-3 demonstrates an example of the changes that occur:

**Example 11–3  Modified Directory Path for Images in a Deployed ADF Skin**

```java
// Reference to an image in an ADF skin prior to deployment to an ADF Library JAR
af|column::sorted-descending-icon-style
{
    background-image: url('images/af_column/colSort_des_ena.png');
}

// Reference to an image in an ADF skin after deployment to an ADF Library JAR
af|column::sorted-descending-icon-style
{
    background-image: url('/adf/skins/skin1/images/af_column/colSort_des_ena.png');
}
```

11.4 Applying an ADF Skin to Your Web Application

You configure an application to use an ADF skin by specifying values in the application's `trinidad-config.xml` file. You specify a value for the `<skin-family>` element that identifies the ADF skin family the application uses at runtime. If you created more than one ADF skin in the ADF skin family, you can version these ADF skins. If you versioned multiple ADF skins in the same ADF skin family, use the `<skin-version>` element in the `trinidad-config.xml` file to identify the specific version that you want the application to use.

If you do not identify a specific ADF skin from an ADF skin family by entering a value for the `<skin-version>` element in the `trinidad-config.xml` file or using the `<default>true</default>` element in the `trinidad-skins.xml` file, the application uses the last skin defined in the `trinidad-skins.xml` file. For more information about versioning ADF skins and how this can determine the ADF skin that your application chooses, see Section 12.5, "Versioning ADF Skins."

Note that you can configure an application page for your end users to dynamically select the ADF skin that they want the application to use. For more information, see *Developing Web User Interfaces with Oracle ADF Faces* (for the release that pertains to the application you are skinning).

11.4.1 How to Apply an ADF Skin to an Application

You apply an ADF skin to an application by modifying the application’s `trinidad-config.xml` file. You do this by editing the application's `trinidad-config.xml` file to specify the ADF skin family to use. Alternatively, you can select the ADF skin family from a list in the ADF View options of JDeveloper's Project Properties dialog.

**To apply an ADF skin to an application:**

1. In the Applications window, double-click the `trinidad-config.xml` file. By default, this file is in the Web Content/WEB-INF node.

2. In the source editor, write entries to specify the value of the `<skin-family>` element and, optionally, the `<skin-version>` element as shown in Example 11–4.
11.4.2 What Happens When You Apply an ADF Skin to an Application

The values that you specify for the `<skin-family>` element and, optionally, the `<skin-version>` element in the `trinidad-config.xml` file determine the ADF skin that the Fusion web application uses at runtime, as shown in Example 11–4.

Example 11–4  `trinidad-config.xml` File

```xml
<?xml version="1.0" encoding="windows-1252"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
  <skin-family>skyros</skin-family>
  <skin-version>v1</skin-version>
</trinidad-config>
```

11.5 Applying an ADF Skin to a Running Web Application

Using Java Management Extensions (JMX), you can apply an ADF skin that is packaged in an ADF Library JAR to a Fusion web application without having to restart the application. To do this, you must configure the Fusion web application's source files, as described in Section 11.5.1, "How to Configure your Fusion Web Application to Accept an Updated ADF Skin." You then use the ADF Skin Editor to connect to the MBean server and deploy the ADF Library JAR containing the ADF skin(s). For more information, see Section 11.5.2, "How to Deploy an ADF Library JAR to an MBean Server." This makes all ADF skins contained in the ADF Library JAR available to the Fusion web application.

11.5.1 How to Configure your Fusion Web Application to Accept an Updated ADF Skin

You make the following changes to the Fusion web application's ViewController project in JDeveloper so that the application can apply a new ADF skin deployed by a MBean server without requiring a restart of the Fusion web application:

- Select the Enable Runtime Skin Updates checkbox in the ADF View page of the application's ViewController project
- Add ADF Faces JMX Runtime 11 to the application's classpath
- (Optional) Add a context initialization parameter to the application's `web.xml` file

The context initialization parameter enables you to specify a user friendly name to identify the Fusion web application rather than use the application's context root.

Note: The Fusion web application must be deployed in an exploded format, as is the case when you run the application in the Integrated WebLogic Server.

To configure your Fusion web application to accept an updated ADF skin:
1. In JDeveloper's Applications window, select the ViewController project.
2. From the main menu, choose Application > Project Properties.
3. In the Project Properties dialog, select the ADF View page and then select the Enable Runtime Skin Updates checkbox.
4. Select the Libraries and Classpath page and verify that ADF Faces JMX Runtime 11 appears in the Classpath Entries list. If it is not, click Add Library.
5. In the Add Library dialog, select ADF Faces JMX Runtime 11 and click OK.
6. Click OK.

7. Optionally, in the Applications window, double-click the web.xml file located in the WEB-INF directory and add a context initialization parameter where you can specify an easy to remember name for your application. Otherwise, the default behavior is to use the context root of the application.

   In the overview editor, click the Application navigation tab and then click the Add icon next to the Context Initialization Parameters table to add an entry for the oracle.adf.view.rich.SKINNING_MBEAN_NAME parameter and set its value to a name that you will use to identify the Fusion web application to the MBean server.

### 11.5.2 How to Deploy an ADF Library JAR to an MBean Server

You deploy the ADF Library JAR that packages the ADF skin(s) to the MBean server. For information about how to create an ADF Library JAR file deployment profile to package the ADF skin(s), see Section 11.3.1, "How to Package an ADF Skin into an ADF Library JAR."

**To deploy an ADF Library JAR to an MBean Server:**

1. In the Applications window, right-click the project that contains the ADF skin(s) and choose Deploy > deployment, where deployment is the name of the ADF Library JAR file deployment profile.

2. In the Deployment Action page, select Deploy to ADF Skin Managed Bean and then click Next.

3. In the Skin Connection page, choose the appropriate option:
   - Click Add to create a new connection to the MBean server and go to Step 4.
   - Choose an existing connection from the Connection dropdown list and go to Step 5.

4. In the Create JMX Connection dialog, complete the fields to connect to the MBean server:
   - **Connection Name:** Enter a name for the connection. The connection name must be a valid Java identifier, and as the name and connection are global across your installation, choose an appropriate and unique name.
   - **Server Type:** The default of Weblogic Server is preselected for connections from the ADF Skin Editor.
   - **Username:** Enter the user name to be authorized for access to the MBean server.
   - **Password:** Enter the password to be associated with the specified user name. An asterisk (*) appears for each character you type in this field.
   - **Protocol:** The ADF Skin Editor uses the t3 protocol to communicate with the MBean server.
   - **Hostname:** Enter a value to identify the machine running the MBean server. Use an IP address or a host name that can be resolved by TCP/IP; for example if the MBean server is on the local machine, use localhost or 127.0.0.1.
   - **Port:** Enter the listen port for the MBean server. The default is whatever the default port number of the Integrated Weblogic Server is (often 7101).
URL Provider Path: Enter the absolute JNDI name of the MBean server. It must start with /jndi/ and be followed by one of:
- weblogic.management.mbeanservers.domainruntime
- weblogic.management.mbeanservers.runtime
- weblogic.management.mbeanservers.edit

Server Install Location: Displays the server install location.

Test Connection: Click to test the connection.

Status: A Success! message indicates that the ADF Skin Editor has been able to connect to the MBean server. Any other message indicates that the connection has failed. Amongst the things you should check before trying Test Connection again are:
- Whether the network is working correctly when the MBean server is not local.
- The values entered in this dialog.

5. In the Application Name field, select the name of the Fusion web application that you want to deploy the ADF Library JAR containing the ADF skin(s) to. Click Find Running Applications to retrieve the list of available applications and to make sure that the application is running.

The name of the application’s root context appears unless you specified the name of the application to be the value that you entered for the oracle.adf.view.rich.SKINNING_MBEAN_NAME parameter, as described in Section 11.5.1, "How to Configure your Fusion Web Application to Accept an Updated ADF Skin."

6. Click Next and then click Finish.

11.5.3 What Happens When You Apply an ADF Skin to a Running Application

The ADF Skin Editor deploys the ADF Library JAR containing the ADF skin(s) to the Fusion web application. This ADF Library JAR contains the ADF skin and other associated files (for example, any images that the ADF skin requires). For more information about the contents of the ADF Library JAR, see Section 11.3.2, "What Happens When You Package an ADF Skin into an ADF Library JAR." The ADF skins are installed in the root directory of the Fusion web application. The trinidad-skins.xml file of the Fusion web application is updated to reference the newly-added ADF skins.

To make the Fusion web application use the newly-available ADF skin, you need to update the value that the trinidad-config.xml file's <skin-family> element references. You can do this manually, as described in Section 11.4.1, "How to Apply an ADF Skin to an Application," or you can specify an EL expression for the element that updates the value programmatically. For more information about this latter option, see the "Customizing the Appearance Using Styles and Skins" chapter in Developing Web User Interfaces with Oracle ADF Faces (for the release that pertains to the application you are skinning).
This chapter provides information to help you if you make changes in the source file of an ADF skin or in the configuration files that control the usage of ADF skins. The chapter also lists and describes the ADF skins provided by Oracle ADF.

This chapter includes the following sections:

- Section 12.1, "Referring to URLs in an ADF Skin's CSS File"
- Section 12.2, "ADF Skinning Framework and Supported Render Kits"
- Section 12.3, "Configuration Files for an ADF Skin"
- Section 12.4, "ADF Skins Provided by Oracle ADF"
- Section 12.5, "Versioning ADF Skins"

### 12.1 Referring to URLs in an ADF Skin's CSS File

An ADF skin's CSS file typically uses a URL to refer to a resource that is external to the file. For example, an image that an application uses to render with an error message. You can refer to a URL from an ADF skin's CSS file in a number of different formats. The supported formats are:

- **Absolute**
  You specify the complete URL to the resource. For example, a URL in the following format:

  
  http://www.mycompany.com/WebApp/Skin/skin1/img/errorIcon.gif

- **Relative**
  You can specify a relative URL if the URL does not start with `/` and no protocol is present. A relative URL is based on the location of the ADF skin's CSS file. For example, if the ADF skin's CSS file directory is `WebApp/Skin/skin1/` and the specified URL is `img/errorIcon.gif`, the final URL is `WebApp/Skin/mySkin/img/errorIcon.gif`

- **Context relative**
  This format of URL is resolved relative to the context root of your web application. You start a context relative root with `/`. For example, if the context relative root of a web application is:

  `/WebApp`

  and the specified URL is:

  `/img/errorIcon.gif`
the resulting URL is:
/WebApp/img/errorIcon.gif

- Server relative

A server relative URL is resolved relative to the web server. This differs to the context relative URL in that it allows you reference a resource located in another application on the same web server. You specify the start of the URL using // For example, write a URL in the following format:
//WebApp/Skin/mySkin/img/errorIcon.gif

The format of URL that you use may be important if you create a Java Archive (JAR) file to package and distribute your ADF skin and its associated files. For more information, see Chapter 11.3, "Packaging an ADF Skin into an ADF Library JAR."

12.2 ADF Skinning Framework and Supported Render Kits

The ADF skinning framework supports the creation of ADF skins for the following render kits:
- org.apache.myfaces.trinidad.desktop
- org.apache.myfaces.trinidad.pda

You can use the design and selectors editors in the ADF Skin Editor and in JDeveloper to create ADF skins for the following render kit:
org.apache.myfaces.trinidad.desktop

You can create an ADF skin for the following render kit using the source editor in the ADF Skin Editor or in JDeveloper:
org.apache.myfaces.trinidad.pda

ADF Faces components delegate the functionality of the component to a component class, and the display of the component to a renderer. By default, all tags for ADF Faces combine the associated component class with an HTML renderer, and are part of the HTML render kit. HTML render kits are included with ADF Faces for display on both desktop and PDA. You cannot customize ADF Faces renderers. However, you can customize how components display using ADF skins.

12.3 Configuration Files for an ADF Skin

The following list describes the configuration files associated with the project for an ADF skin. You modify values in these files while you develop your ADF skin or when you finish development and want to apply the finished ADF skin to an application.
- trinidad-skins.xml

This file registers the ADF skins that you create, as described in Section 4.3, "Creating an ADF Skin File." Example 12–1 demonstrates how to register a number of ADF skins that extends from a sample of the ADF skins described in Table 12–1.

Example 12–1 Registering an ADF Skin in the trinidad-skins.xml File

<!-- Use the following values in the trinidad-skins.xml file if you want to extend the fusionFx-v1.2 skin. -->
<skin>
  <id>yourSkin.desktop</id>
  <family>yourSkinFamily</family>
</skin>
Configuration Files for an ADF Skin

```xml
<extends>fusionFx-v1.2.desktop</extends>
...
</skin>

<!-- Use the following values in the trinidad-skins.xml file if you want to extend
the skyros-v1 skin. -->
<skin>
  <id>yourSkin.desktop</id>
  <family>yourSkinFamily</family>
  <extends>skyros-v1.desktop</extends>
  ...
</skin>

For more information about this file, see the "Configuration in trinidad-skins.xml"
section in Developing Web User Interfaces with Oracle ADF Faces (for the release that
pertains to the application you are skinning).

- trinidad-config.xml

You configure the <skin-family> element in this configuration file to tell the
application what ADF skin to use, as described in Section 11.4, "Applying an ADF
Skin to Your Web Application." Example 12–2 demonstrates a number of examples
that show how to configure your web application to use some of the ADF skins
listed in Table 12–1.

**Example 12–2 Configuring an Application's trinidad-config.xml File to Use an ADF Skin**

```xml
<!-- Use the following value in the trinidad-config.xml file if you want your
application to use the fusionFx-simple-v2 skin -->
<skin-family>fusionFx-simple</skin-family>
<skin-version>v2</skin-version>

<!-- Use the following value in the trinidad-config.xml file if you want your
application to use the fusionFx-v2.1 skin. -->
<skin-family>fusionFx</skin-family>
<skin-version>v2.1</skin-version>

<!-- Use the following value in the trinidad-config.xml file if you want your
application to use the skyros skin. -->
<skin-family>skyros</skin-family>
<skin-version>v1</skin-version>

For more information about this file, see the "Configuration in
trinidad-config.xml" section in Developing Web User Interfaces with Oracle ADF Faces
(for the release that pertains to the application you are skinning).

- web.xml

You can configure context initialization parameters in this file to facilitate the
development and testing of your ADF skin, as described in Section 11.2, "Testing
Changes in Your ADF Skin." You can also configure a context initialization
parameter (org.apache.myfaces.trinidad.skin.MAX_SKINS_CACHED) to
specify the maximum number of unique ADF skins (for example, fusion or
fusionFx-simple) for which you store information in memory about the
generated CSS files. Using this context initialization parameter can help maintain
the performance of your application if you use many different skins.

For more information about the web.xml file and context initialization
parameters, see the "Configuration in web.xml" section in Developing Web User
12.4 ADF Skins Provided by Oracle ADF

Oracle ADF provides a variety of ADF skins from which you can extend when you create a new ADF skin. Table 12–1 describes the differences between each of these ADF skins. The value you choose for the Target Application Release property, as described in Section 4.2, "Creating ADF Skin Applications and ADF Skin Projects," determines the ADF skins available to you to extend from. Not all ADF skin listed in Table 12–1 will be available to you. For example, if you choose 11.1.1.4.x as the value for the Target Application Release property the skyros skin is not available to extend.

The Base Skin page of the Create ADF Skin dialog that appears when you create an ADF skin, as described in Section 4.3, "Creating an ADF Skin File," recommends the appropriate ADF skin to extend from based on the release of Oracle ADF for which you want to create an ADF skin. For example, if you choose 12.1.2.0.x as the value for the Target Application Release property, the recommended ADF skin to extend from is skyros-v1.desktop.

You can apply any of the ADF skins listed in Table 12–1 to your web application. For more information, see Section 12.3, "Configuration Files for an ADF Skin." For a diagram that illustrates the inheritance relationship between the ADF skins, see Section 1.4, "Inheritance Relationship of the ADF Skins Provided by Oracle ADF."

Table 12–1 ADF Skins Provided by Oracle ADF

<table>
<thead>
<tr>
<th>ADF Skin</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>simple</td>
<td>Contains only minimal formatting.</td>
</tr>
<tr>
<td>skyros-v1</td>
<td>Extends the simple skin. It provides a colorful look and feel to applications that use it. The skyros skin also provides a simpler DOM structure alternative for image borders in comparison to, for example, the fusion skins. You can provide a simpler DOM structure alternative for image borders in non-skyros skins by setting values for a &lt;feature&gt; element in the trinidad-skins.xml file, as described in Section 6.6, &quot;Providing a Simple Border Style for ADF Skins.&quot;</td>
</tr>
<tr>
<td>fusion-base</td>
<td>Extends the simple skin. The Fusion and Fusion Simple families of ADF skin extend this skin (for example, the fusion and fusionFx-simple skins). Oracle recommends that you do not extend from the fusion-base skin.</td>
</tr>
<tr>
<td>fusion</td>
<td>Extends the fusion-base skin. This skin provides a significant amount of styling. This skin is deprecated.</td>
</tr>
<tr>
<td>fusion-11.1.1.3.0</td>
<td>Extends the fusion skin. This skin makes the hierarchy structure in certain components that render tabs clearer. These components are panelTabbed, navigationPane (attribute hint=&quot;tabs&quot;), and decorativeBox. This skin also defines a more subtle background image for disclosed panelAccordion component panes to make text that appears in these panes easier to read.</td>
</tr>
</tbody>
</table>
fusionFx-v1 Extends the fusion-11.1.1.3.0 skin. This skin contains design improvements and changes to address a number of issues. Specifically, it adds:

- A background color to the .AFMaskingFrame global style selector to prevent the display of content from an underlying frame when an inline popup displays in certain browsers.

- A boolean ADF skin property, -tr-stretch-dropdown-table, for the inputComboboxListOfValues component. This property determines whether the table in the list stretches to show the content of the table columns or limits the width of the table to the width of the input field in the inputComboboxListOfValues component.

- The inlineFrame component displays an image that serves as a loading indicator until the browser determines that the frame's contents have been loaded.

  You can implement this functionality in an ADF skin that you create. The af|inlineFrame selector has "busy" and "flow" pseudo-classes that enable you to do this. The inlineFrame component only generates an IFrame element when the parent component does not stretch the inlineFrame component (the inlineFrame component is flowing). Use af|inlineFrame:busy:flow to define a background-image style that references a loading indicator. When the parent component stretches the inlineFrame component, the generated content is more complex. This complexity allows you to define a content image URL using the af|inlineFrame::status-icon and an optional additional background-image using the af|inlineFrame::status-icon-style. It also allows you to reuse images that other component selectors use. For example, the carousel component's af|carousel::status-icon and af|carousel::status-icon-style selectors. Use skinning aliases to reuse these images.

  The following global selectors have also been introduced that you can use if you implement this functionality in your ADF skin:

- .AFBackgroundImageStatus:alias use to reference the background image used in af|inlineFrame::busy:flow.

- .AFStatusIcon::alias use to reference the af|carousel::status-icon and af|inlineFrame::status-icon.

- .AFStatusIconStyle::alias use to reference the af|carousel::status-icon-style and af|inlineFrame::status-icon-style.

  A resource key (af_inlineFrame.LABEL_FETCHING) defines the string to display for the inlineFrame component's loading icon.

fusionFx-v1.1 Extends the fusionFx-v1 skin. It adds support for the ability to clear Query-By-Example (QBE) filters in an af:table component.

fusionFx-v1.2 Extends the fusionFx-v1.1 skin. It contains a number of user interface enhancements, including optimizations for when your application renders in a touch screen device.

fusionFx-v1.3 Extends the fusionFx-v1.2 skin. Changes include a new skin property (-tr-pop-out-animation-duration) and a number of modified pseudo-elements for the af|carousel selector.

fusionFx-v2 Extends from the fusionFx-v1 skin. It makes the hierarchy structure in certain components that render tabs clearer. These components are panelTabbed, navigationPane (attribute hint="tabs"), and decorativeBox. This skin also defines a more subtle background image for disclosed panelAccordion component panes to make text that appears in these panes easier to read.
12.5 Versioning ADF Skins

You can specify version numbers for your ADF skins in the trinidad-skins.xml file using the <version> element. Use this optional capability if you want to distinguish between ADF skins that have the same value for the <family> element in the trinidad-skins.xml file. Note that when you configure an application to use a particular ADF skin, you do so by specifying values in the trinidad-config.xml file, as described in section Section 11.4, "Applying an ADF Skin to Your Web Application."
12.5.1 How to Version an ADF Skin

You specify a version for your ADF skin by entering a value for the `<version>` element in the `trinidad-skins.xml` file.

To version an ADF skin:
1. In the Applications window, double-click the `trinidad-skins.xml` file. By default, this is in the Web Content/WEB-INF node.
2. In the Structure window, right-click the skin node for the ADF skin that you want to version and choose Insert inside skin > version.
3. In the Insert version dialog, select true from the default list if you want your application to use this version of the ADF skin when no value is specified in the `<skin-version>` element of the `trinidad-config.xml` file, as described in Section 11.4, "Applying an ADF Skin to Your Web Application."
4. Enter a value in the name field. For example, enter v1 if this is the first version of the ADF skin.
5. Click OK.

12.5.2 What Happens When You Version ADF Skins

Example 12–3 shows an example `trinidad-skins.xml` that references three ADF skins (`skin1.desktop`, `skin2.desktop`, and `skin3.desktop`). Each of these ADF skins have the same value for the `<family>` element (test). The values for the child elements of the `<version>` elements distinguish between each of these ADF skins. At runtime, an application that specifies test as the value for the `<skin-family>` element in the application's `trinidad-config.xml` file uses `skin1.desktop` because this ADF skin is configured as the default skin in the `trinidad-skins.xml` file. You can override this behavior by specifying a value for the `<skin-version>` element in the `trinidad-config.xml` file, as described in Section 11.4, "Applying an ADF Skin to Your Web Application." For example, if you specify v2 as a value for the `<skin-version>` element in the `trinidad-config.xml` file, the application uses `skin2.desktop` instead of `skin1.desktop` that is defined as the default in the `trinidad-skins.xml` file.

If you do not specify the skin version to pick (using the `<skin-version>` element in the `trinidad-config.xml` file), then the application uses the skin that is defined as the default using the `<default>true</default>` element in the `trinidad-skins.xml` file. If you do not specify a default skin, the application uses the last ADF skin defined in the `trinidad-skins.xml` file. In Example 12–3, the last ADF skin to be defined is `skin3.desktop`.

Example 12–3  `trinidad-skins.xml` File with Versioned ADF Skin Files

```xml
<?xml version="1.0" encoding="windows-1252"?>
<skins xmlns="http://myfaces.apache.org/trinidad/skin">
  <skin>
    <id>skin1.desktop</id>
    <family>test</family>
    <extends>skyros-v1.desktop</extends>
    <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
    <style-sheet-name>skins/skin1/skin1.css</style-sheet-name>
    <version>
      <default>true</default>
      <name>v1</name>
    </version>
  </skin>
  ...
</skins>
```
<skin>
  <id>skin2.desktop</id>
  <family>test</family>
  <extends>skin1.desktop</extends>
  <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
  <style-sheet-name>skins/skin2/skin2.css</style-sheet-name>
  <version>
    <name>v2</name>
  </version>
</skin>

<skin>
  <id>skin3.desktop</id>
  <family>test</family>
  <extends>skin2.desktop</extends>
  <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
  <style-sheet-name>skins/skin3/skin3.css</style-sheet-name>
  <version>
    <name>v3</name>
  </version>
</skin>
