Oracle® Fusion Middleware
Developing JAX-RPC Web Services for Oracle WebLogic Server
12.1.3
12c (12.1.3)
E47707-03

August 2015
Documentation for software developers that describes how to develop WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

1 Introduction to JAX-RPC Web Services

2 Examples for JAX-RPC Web Service Developers
  2.1 Creating a Simple HelloWorld Web Service .......................................................................................... 2-1
  2.1.1 Sample HelloWorldImpl.java JWS File ........................................................................................ 2-3
  2.1.2 Sample Ant Build File for HelloWorldImpl.java ........................................................................ 2-4
  2.2 Creating a Web Service With User-Defined Data Types ..................................................................... 2-5
  2.2.1 Sample BasicStruct JavaBean ........................................................................................................ 2-8
  2.2.2 Sample ComplexImpl.java JWS File ............................................................................................. 2-8
  2.2.3 Sample Ant Build File for ComplexImpl.java JWS File .............................................................. 2-9
  2.3 Creating a Web Service from a WSDL File ......................................................................................... 2-11
  2.3.1 Sample WSDL File ......................................................................................................................... 2-14
  2.3.2 Sample TemperaturePortType Java Implementation File .......................................................... 2-15
  2.3.3 Sample Ant Build File for TemperatureService ........................................................................ 2-16
  2.4 Invoking a Web Service from a Java SE Client ................................................................................... 2-17
  2.4.1 Sample Java Client Application ...................................................................................................... 2-20
  2.4.2 Sample Ant Build File For Building Java Client Application .................................................... 2-21
  2.5 Invoking a Web Service from a WebLogic Web Service .................................................................... 2-21
  2.5.1 Sample ClientServiceImpl.java JWS File ..................................................................................... 2-24
  2.5.2 Sample Ant Build File For Building ClientServiceImpl ............................................................. 2-25

3 Developing JAX-RPC Web Services
  3.1 Overview of the WebLogic Web Service Programming Model .......................................................... 3-1
  3.2 Configuring Your Domain For Web Services Features ....................................................................... 3-2
  3.3 Developing WebLogic Web Services Starting From Java: Main Steps ............................................. 3-3
  3.4 Developing WebLogic Web Services Starting From a WSDL File: Main Steps ................................. 3-4
4 Programming the JWS File

4.1 Overview of JWS Files and JWS Annotations ........................................................................... 4-1
4.2 Java Requirements for a JWS File .............................................................................................. 4-2
4.3 Programming the JWS File: Typical Steps ................................................................................. 4-2
4.3.1 Example of a JWS File ........................................................................................................... 4-3
4.3.2 Specifying that the JWS File Implements a Web Service (@WebService Annotation) .................. 4-4
4.3.3 Specifying the Mapping of the Web Service to the SOAP Message Protocol (@SOAPBinding Annotation) ........................................................................................................... 4-5
4.3.4 Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation) ...................................................................................................................... 4-5
4.3.5 Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and @OneWay Annotations) .......................................................................................................................... 4-6
4.3.6 Customizing the Mapping Between Operation Parameters and WSDL Elements (@WebParam Annotation) .................................................................................................................. 4-7
4.3.7 Customizing the Mapping Between the Operation Return Value and a WSDL Element (@WebResult Annotation) ............................................................................................................. 4-7
4.4 Accessing Run-Time Information About a Web Service ............................................................ 4-8
4.4.1 Using JwsContext to Access Run-Time Information ................................................................. 4-8
4.4.1.1 Guidelines for Accessing the Web Service Context .............................................................. 4-8
4.4.1.2 Methods of the JwsContext ............................................................................................... 4-9
4.4.2 Using the Stub Interface to Access Run-Time Information ....................................................... 4-12
4.5 Should You Implement a Stateless Session EJB? ....................................................................... 4-13
4.5.1 Programming Guidelines When Implementing an EJB in Your JWS File ................................ 4-13
4.5.2 Example of a JWS File That Implements an EJB ................................................................. 4-14
4.6 Programming the User-Defined Java Data Type ...................................................................... 4-15
4.7 Throwing Exceptions .................................................................................................................... 4-16
4.8 Invoking Another Web Service from the JWS File .................................................................... 4-18
8 Using Web Services Reliable Messaging

8.1 Overview of Web Service Reliable Messaging ........................................................................ 8-1
8.1.1 Using WS-Policy to Specify Reliable Messaging Policy Assertions ................................ 8-3
8.1.2 Managing the Life Cycle of the Reliable Message Sequence ........................................... 8-3
8.2 Using Web Service Reliable Messaging: Main Steps ............................................................ 8-4
8.2.1 Prerequisites ..................................................................................................................... 8-6
8.3 Configuring the Destination WebLogic Server Instance .................................................... 8-6
8.4 Configuring the Source WebLogic Server Instance ........................................................... 8-8
8.5 Creating the Web Service Reliable Messaging WS-Policy File ............................................ 8-9
8.5.1 Creating a Custom WS-Policy File Using WS-ReliableMessaging Policy Assertions
Version 1.1 .......................................................................................................................... 8-11
8.5.2 Creating a Custom WS-Policy File Using WS-ReliableMessaging Policy Assertions
Version 1.0 (Deprecated) ........................................................................................................ 8-12
8.5.3 Using Multiple Policy Alternatives ................................................................................ 8-14
8.6 Programming Guidelines for the Reliable JWS File ........................................................... 8-14
8.6.1 Using the @Policy Annotation ......................................................................................... 8-16
8.6.2 Using the @Oneway Annotation ....................................................................................... 8-18
8.6.3 Using the @BufferQueue Annotation ............................................................................. 8-18
8.6.4 Using the @ReliabilityBuffer Annotation ...................................................................... 8-18
8.7 Configuring Reliable Messaging for a Reliable Web Service ............................................. 8-19
8.7.1 Using the Administration Console ................................................................................ 8-21
8.7.2 Using WLST .................................................................................................................. 8-22
8.8 Programming Guidelines for the JWS File That Invokes a Reliable Web Service ............... 8-22
8.9 Updating the build.xml File for a Client of a Reliable Web Service .................................... 8-26
8.10 Using Reliable Messaging With MTOM ............................................................................ 8-27
8.11 Client Considerations When Redeploying a Reliable Web Service .................................. 8-28
8.12 Using Reliable Messaging With a Proxy Server ................................................................. 8-28

9 Creating Conversational Web Services

9.1 Overview of Conversational Web Services ........................................................................ 9-1
9.2 Creating a Conversational Web Service: Main Steps .......................................................... 9-2
9.3 Programming Guidelines for the Conversational JWS File ................................................ 9-4
9.4 Programming Guidelines for the JWS File That Invokes a Conversational Web Service .... 9-6
9.5 ConversationUtils Utility Class .......................................................................................... 9-9
9.6 Updating the build.xml File for a Client of a Conversational Web Service ................. 9-9
9.7 Updating a Stand-Alone Java Client to Invoke a Conversational Web Service ................ 9-10
9.8 Example Conversational Web Service .NET Client .......................................................... 9-11
9.8.1 ConversationService.java File ...................................................................................... 9-11
9.8.2 Service.cs File ............................................................................................................. 9-13
9.8.3 build.xml File ............................................................................................................ 9-19
9.9 Client Considerations When Redeploying a Conversational Web Service ....................... 9-21
This preface describes the document accessibility features and conventions used in this guide—Developing JAX-RPC Web Services for Oracle WebLogic Server 12.1.3.

**Documentation Accessibility**

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info) or visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs) if you are hearing impaired.

**Conventions**

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><strong>italic</strong></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
What's New in This Guide

The following topics introduce the new and changed features of WebLogic Java API for XML-based RPC (JAX-RPC) web services in Oracle Fusion Middleware 12c (12.1.3), and provides pointers to additional information.

New and Changed Features for 12c (12.1.3)
For Oracle Fusion Middleware 12c (12.1.3), this document does not contain any new or changed features.

New and Changed Features for 12c (12.1.2)
Oracle Fusion Middleware 12c (12.1.2) includes the following new and changed features for this document:

- For 12c (12.1.3), the contents of the following guides, delivered in Oracle Fusion Middleware Release 11g, have been merged into this single document:
  - *Getting Started With JAX-RPC Web Services for Oracle WebLogic Server*
  - *Programming Advanced Features of JAX-RPC Web Services for Oracle WebLogic Server*

- New standalone web service client JAR file that supports basic JAX-RPC client-side functionality. See Section 6.4, "Using a Standalone Client JAR File When Invoking Web Services".
Part I introduces developing WebLogic web services using the Java API for XML-based RPC (JAX-RPC).

Sections include:

- Chapter 1, "Introduction to JAX-RPC Web Services"
- Chapter 2, "Examples for JAX-RPC Web Service Developers"
Introduction to JAX-RPC Web Services

This chapter provides a summary table of topics for software developers who program WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

JAX-RPC is a specification that defines the Java APIs for making XML-based remote procedure calls (RPC). In particular, these APIs are used to invoke and get a response from a web service using SOAP 1.1, and XML-based protocol for exchange of information in a decentralized and distributed environment. For more information, see http://java.net/projects/jax-rpc/.

The following table summarizes the contents of this guide.

For an overview of WebLogic web services, standards, samples, and related documentation, see *Understanding WebLogic Web Services for Oracle WebLogic Server*.

For information about WebLogic web service security, see *Securing WebLogic Web Services for Oracle WebLogic Server*.

For definitions of unfamiliar terms found in this and other books, see the Glossary.
This chapter describes common use cases and examples for WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following sections:

- Creating a Simple HelloWorld Web Service
- Creating a Web Service With User-Defined Data Types
- Creating a Web Service from a WSDL File
- Invoking a Web Service from a Java SE Client
- Invoking a Web Service from a WebLogic Web Service

Each use case provides step-by-step procedures for creating simple WebLogic web services and invoking an operation from a deployed web service. The examples include basic Java code and Ant build.xml files that you can use in your own development environment to recreate the example, or by following the instructions to create and run the examples in an environment that is separate from your development environment.

The use cases do not go into detail about the processes and tools used in the examples; later chapters are referenced for more detail.

### 2.1 Creating a Simple HelloWorld Web Service

This section describes how to create a very simple web service that contains a single operation. The Java Web Service (JWS) file that implements the web service uses just the one required JWS annotation: @WebService. A JWS file is a standard Java file that uses JWS metadata annotations to specify the shape of the web service. Metadata annotations were introduced with JDK 5.0, and the set of annotations used to annotate web service files are called JWS annotations. WebLogic web services use standard JWS annotations. For a complete list of JWS annotations that are supported, see "Web Service Annotation Support" in WebLogic Web Services Reference for Oracle WebLogic Server.

The following example shows how to create a web service called HelloWorldService that includes a single operation, sayHelloWorld. For simplicity, the operation returns the inputted String value.

1. Set your WebLogic Server environment.

   Open a command window and execute the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the `bin` subdirectory of your domain
directory. The default location of WebLogic Server domains is \texttt{ORACLE\_HOME/user\_projects/domains/domainName}, where \texttt{ORACLE\_HOME} is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and \texttt{domainName} is the name of your domain.

2. Create a project directory, as follows:

\texttt{prompt> mkdir /myExamples/hello\_world}

3. Create a \texttt{src} directory under the project directory, as well as subdirectories that correspond to the package name of the JWS file (shown later in this procedure):

\texttt{prompt> cd /myExamples/hello\_world}
\texttt{prompt> mkdir src/examples/webservices/hello\_world}

4. Create the JWS file that implements the web service.

Open your favorite Java IDE or text editor and create a Java file called \texttt{HelloWorldImpl.java} using the Java code specified in Section 2.1.1, "Sample HelloWorldImpl.java JWS File."

The sample JWS file shows a Java class called \texttt{HelloWorldImpl} that contains a single public method, \texttt{sayHelloWorld(String)}. The \texttt{@WebService} annotation specifies that the Java class implements a web service called \texttt{HelloWorldService}. By default, all public methods are exposed as operations.

5. Save the \texttt{HelloWorldImpl.java} file in the \texttt{src/examples/webservices/hello\_world} directory.

6. Create a standard Ant \texttt{build.xml} file in the project directory (\texttt{myExamples/hello\_world/src}) and add a \texttt{taskdef} Ant task to specify the full Java classname of the \texttt{jwsc} task:

\begin{verbatim}
<project name="webservices-hello_world" default='all'>
   <taskdef name="jwsc" class="weblogic.wsee.tools.anttasks.JwscTask" />
</project>
\end{verbatim}

See Section 2.1.2, "Sample Ant Build File for HelloWorldImpl.java" for a full sample \texttt{build.xml} file that contains additional targets from those described in this procedure, such as \texttt{clean}, \texttt{undeploy}, \texttt{client}, and \texttt{run}. The full \texttt{build.xml} file also uses properties, such as \texttt{$(ear-dir)}), rather than always using the hard-coded name for the EAR directory.

7. Add the following call to the \texttt{jwsc} Ant task to the \texttt{build.xml} file, wrapped inside of the \texttt{build-service} target:

\begin{verbatim}
<target name="build-service">
   <jwsc srcdir="src" destdir="output/helloWorldEar">
      <jws file="examples/webservices/hello_world/HelloWorldImpl.java" type="JAXRPC"/>
   </jwsc>
</target>
\end{verbatim}

The \texttt{jwsc} WebLogic web service Ant task generates the supporting artifacts (such as the deployment descriptors, serialization classes for any user-defined data types, the WSDL file, and so on), compiles the user-created and generated Java code, and archives all the artifacts into an Enterprise Application EAR file that you later deploy to WebLogic Server.
8. Execute the jwsc Ant task by specifying the build-service target at the command line:

```
prompt> ant build-service
```

See the output/helloWorldEar directory to view the files and artifacts generated by the jwsc Ant task.

9. Start the WebLogic Server instance to which the web service will be deployed.

10. Deploy the web service, packaged in an enterprise application, to WebLogic Server, using either the WebLogic Server Administration Console or the wlddeploy Ant task. In either case, you deploy the helloWorldEar Enterprise application, located in the output directory.

To use the wlddeploy Ant task, add the following target to the build.xml file:

```
<taskdef name="wldeploy"
classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="deploy">
<wldeploy action="deploy">
  name="helloWorldEar" source="output/helloWorldEar"
  user="${wls.username}" password="${wls.password}"
  verbose="true"
  adminurl="t3://${wls.hostname}:${wls.port}"
  targets="${wls.server.name}" />
</target>
```

Substitute the values for wls.username, wls.password, wls.hostname, wls.port, and wls.server.name that correspond to your WebLogic Server instance.

Deploy the WAR file by executing the deploy target:

```
prompt> ant deploy
```

11. Test that the web service is deployed correctly by invoking its WSDL in your browser:

```
http://host:port/HelloWorldImpl/HelloWorldImpl?WSDL
```

You construct the URL using the values of the contextPath and serviceUri attributes of the WLHttpTransport JWS annotation; however, because the JWS file in this use case does not include the WLHttpTransport annotation, use the default values for the contextPath and serviceUri attributes: the name of the Java class in the JWS file. These attributes will be set explicitly in the next example, Section 2.2, "Creating a Web Service With User-Defined Data Types." Use the hostname and port relevant to your WebLogic Server instance.

You can use the clean, build-service, undeploy, and deploy targets in the build.xml file to iteratively update, rebuild, undeploy, and redeploy the web service as part of your development process.

To run the web service, you need to create a client that invokes it. See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a web service.

### 2.1.1 Sample HelloWorldImpl.java JWS File

```java
package examples.webservices.hello_world;
// Import the @WebService annotation
import javax.jws.WebService;
@WebService(name="HelloWorldPortType", serviceName="HelloWorldService")
```
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHelloWorld
 */
public class HelloWorldImpl {
   // By default, all public methods are exposed as Web Services operation
   public String sayHelloWorld(String message) {
      try {
         System.out.println("sayHelloWorld:" + message);
      } catch (Exception ex) {
         ex.printStackTrace();
      }
      return "Here is the message: " + message + ";";
   }
}

2.1.2 Sample Ant Build File for HelloWorldImpl.java

The following build.xml file uses properties to simplify the file.

```xml
<project name="webservices-hello_world" default="all">
<!-- set global properties for this build -->
<property name="wls.username" value="weblogic" />
<property name="wls.password" value="weblogic" />
<property name="wls.hostname" value="localhost" />
<property name="wls.port" value="7001" />
<property name="wls.server.name" value="myserver" />
<property name="ear.deployed.name" value="helloWorldEar" />
<property name="example-output" value="output" />
<property name="ear-dir" value="${example-output}/helloWorldEar" />
<property name="clientclass-dir" value="${example-output}/clientclasses" />
<path id="client.class.path">
   <pathelement path="${clientclass-dir}"/>
   <pathelement path="${java.class.path}"/>
</path>
<taskdef name="jwsc" 
   classname="weblogic.wsee.tools.anttasks.JwscTask"/>
<taskdef name="clientgen" 
   classname="weblogic.wsee.tools.anttasks.ClientGenTask"/>
<taskdef name="wldeploy" 
   classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="all" depends="clean,build-service,deploy,client" />
<target name="clean" depends="undeploy">
   <delete dir="${example-output}"/>
</target>
<target name="build-service">
   <jwsc 
      srcdir="src" 
      destdir="${ear-dir}">
      <jws file="examples/webservices/hello_world/HelloWorldImpl.java" 
         type="JAXRPC"/>
   </jwsc>
</target>
<target name="deploy">
   <wldeploy action="deploy" name="${ear.deployed.name}" 
      source="${ear-dir}" user="${wls.username}" 
      password="${wls.password}" verbose="true" 
      adminurl="t3://${wls.hostname}:${wls.port}" 
      targets="${wls.server.name}"/>
</target>
</project>
```
2.2 Creating a Web Service With User-Defined Data Types

The preceding use case uses only a simple data type, String, as the parameter and return value of the web service operation. This next example shows how to create a web service that uses a user-defined data type, in particular a JavaBean called BasicStruct, as both a parameter and a return value of its operation.

There is actually very little a programmer has to do to use a user-defined data type in a web service, other than to create the Java source of the data type and use it correctly in the JWS file. The jwsc Ant task, when it encounters a user-defined data type in the JWS file, automatically generates all the data binding artifacts needed to convert data between its XML representation (used in the SOAP messages) and its Java representation (used in WebLogic Server). The data binding artifacts include the XML Schema equivalent of the Java user-defined type, the JAX-RPC type mapping file, and so on.

The following procedure is very similar to the procedure in Section 2.1, "Creating a Simple HelloWorld Web Service." For this reason, although the procedure does show all the needed steps, it provides details only for those steps that differ from the simple HelloWorld example.

1. Set your WebLogic Server environment.

Open a command window and execute the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is ORACLE_HOME/user_projects/domains/domainName, where ORACLE_HOME is the directory you specified.
Creating a Web Service With User-Defined Data Types

as Oracle Home when you installed Oracle WebLogic Server and *domainName* is the name of your domain.

2. Create a project directory:
   ```
   prompt> mkdir /myExamples/complex
   ```

3. Create a `src` directory under the project directory, as well as subdirectories that correspond to the package name of the JWS file (shown later in this procedure):
   ```
   prompt> cd /myExamples/complex
   prompt> mkdir src/examples/webservices/complex
   ```

4. Create the source for the BasicStruct JavaBean.

   Open your favorite Java IDE or text editor and create a Java file called `BasicStruct.java`, in the project directory, using the Java code specified in Section 2.2.1, "Sample BasicStruct JavaBean."

5. Save the `BasicStruct.java` file in the `src/examples/webservices/complex` subdirectory of the project directory.

6. Create the JWS file that implements the web service using the Java code specified in Section 2.2.2, "Sample ComplexImpl.java JWS File."

   The sample JWS file uses several JWS annotations: `@WebMethod` to specify explicitly that a method should be exposed as a web service operation and to change its operation name from the default method name `echoStruct` to `echoComplexType`; `@WebParam` and `@WebResult` to configure the parameters and return values; `@SOAPBinding` to specify the type of web service; and `@WLHttpTransport` to specify the URI used to invoke the web service. The `ComplexImpl.java` JWS file also imports the `examples.webservice.complex.BasicStruct` class and then uses the BasicStruct user-defined data type as both a parameter and return value of the `echoStruct()` method.

   For more in-depth information about creating a JWS file, see Chapter 4, "Programming the JWS File."

7. Save the `ComplexImpl.java` file in the `src/examples/webservices/complex` subdirectory of the project directory.

8. Create a standard Ant `build.xml` file in the project directory and add a `taskdef` Ant task to specify the fully Java classname of the `jwsc` task:
   ```
   <project name="webservices-complex" default="all">
      <taskdef name="jwsc"
         classname="weblogic.wsee.tools.anttasks.JwscTask" />
   </project>
   ```

   See Section 2.2.3, "Sample Ant Build File for ComplexImpl.java JWS File" for a full sample `build.xml` file.

9. Add the following call to the `jwsc` Ant task to the `build.xml` file, wrapped inside of the `build-service` target:
   ```
   <target name="build-service">
      <jwsc
         srcdir="src"
         destdir="output/ComplexServiceEar" >
      <jws file="examples/webservices/complex/ComplexImpl.java"
          type="JAXRPC">
         <WLHttpTransport
            contextPath="complex" serviceUri="ComplexService"
In the preceding example:

- The type attribute of the `<jws>` element specifies the type of web service (JAX-WS or JAX-RPC).
- The `<WLHttpTransport>` child element of the `<jws>` element of the jwsc Ant task specifies the context path and service URI sections of the URL used to invoke the web service over the HTTP/S transport, as well as the name of the port in the generated WSDL. This value overrides the value specified in the JWS file using the `@WLHttpTransport` attribute. For more information about defining the context path, see "Defining the Context Path of a WebLogic Web Service" on page 3-9.

10. Execute the jwsc Ant task:

    prompt> ant build-service

    See the output/ComplexServiceEar directory to view the files and artifacts generated by the jwsc Ant task.

11. Start the WebLogic Server instance to which the web service will be deployed.

12. Deploy the web service, packaged in the ComplexServiceEar Enterprise Application, to WebLogic Server, using either the WebLogic Server Administration Console or the wldeploy Ant task. For example:

    prompt> ant deploy

13. Deploy the web service, packaged in an Enterprise Application, to WebLogic Server, using either the WebLogic Server Administration Console or the wldeploy Ant task. In either case, you deploy the ComplexServiceEar Enterprise application, located in the output directory.

    To use the wldeploy Ant task, add the following target to the build.xml file:

    ```xml
    <taskdef name="wldeploy"
             classname="weblogic.ant.taskdefs.management.WLDeploy"/>
    <target name="deploy">
        <wldeploy action="deploy"
                   name="ComplexServiceEar" source="output/ComplexServiceEar"
                   user="${wls.username}" password="${wls.password}" verbose="true"
                   adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
    </target>
    
    Substitute the values for wls.username, wls.password, wls.hostname, wls.port, and wls.server.name that correspond to your WebLogic Server instance.

    Deploy the WAR file by executing the deploy target:

    prompt> ant deploy

14. Test that the web service is deployed correctly by invoking its WSDL in your browser:

    http://host:port/complex/ComplexService?WSDL
To run the web service, you need to create a client that invokes it. See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a web service.

2.2.1 Sample BasicStruct JavaBean

```java
package examples.webservices.complex;
/**
 * Defines a simple JavaBean called BasicStruct that has integer, String, and String[] properties
 */
public class BasicStruct {
    // Properties
    private int intValue;
    private String stringValue;
    private String[] stringArray;
    // Getter and setter methods
    public int getIntValue() {
        return intValue;
    }
    public void setIntValue(int intValue) {
        this.intValue = intValue;
    }
    public String getStringValue() {
        return stringValue;
    }
    public void setStringValue(String stringValue) {
        this.stringValue = stringValue;
    }
    public String[] getStringArray() {
        return stringArray;
    }
    public void setStringArray(String[] stringArray) {
        this.stringArray = stringArray;
    }
    public String toString() {
        return "IntValue=\"+intValue+\", StringValue=\"+stringValue+\"
    }
}
```

2.2.2 Sample ComplexImpl.java JWS File

```java
package examples.webservices.complex;
// Import the standard JWS annotation interfaces
import javax.jws.WebMethod;
import javax.jws.WebParam;
import javax.jws.WebResult;
import javax.jws.WebService;
import javax.jws.soap.SOAPBinding;
// Import the WebLogic-specific JWS annotation interface
import weblogic.jws.WLHttpTransport;
// Standard JWS annotation that specifies the portType name of the Web
// Service is "ComplexPortType", its public service name is "ComplexService",
// and the targetNamespace used in the generated WSDL is "http://example.org"
@WebService(serviceName="ComplexService", name="ComplexPortType",
targetNamespace="http://example.org")
// Standard JWS annotation that specifies this is a document-literal-wrapped
```
// Web Service
@WebService(style=SOAPBinding.Style.DOCUMENT,
  use=SOAPBinding.Use.LITERAL,
  parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
// WebLogic-specific JWS annotation that specifies the context path and service
@WebHttpTransport(contextPath="complex", serviceUri="ComplexService",
  portName="ComplexServicePort")
/**
 * This JWS file forms the basis of a WebLogic Web Service. The Web Service
 * has two public operations:
 * - echoInt(int)
 * - echoComplexType(BasicStruct)
 *
 * The Web Service is defined as a "document-literal" service, which means
 * that the SOAP messages have a single part referencing an XML Schema element
 * that defines the entire body.
 */
public class ComplexImpl {
  // Standard JWS annotation that specifies that the method should be exposed
  // as a public operation. Because the annotation does not include the
  // member-value 'operationName', the public name of the operation is the
  // same as the method name: echoInt.
  //
  // The WebResult annotation specifies that the name of the result of the
  // operation in the generated WSDL is "IntegerOutput", rather than the
  // default name "return". The WebParam annotation specifies that the input
  // parameter name in the WSDL file is "IntegerInput" rather than the Java
  // name of the parameter, "input".
  @WebMethod()
  @WebResult(name="IntegerOutput",
    targetNamespace="http://example.org/complex")
  public int echoInt(
    @WebParam(name="IntegerInput",
      targetNamespace="http://example.org/complex")
    int input)
  {
    System.out.println("echoInt " + input + ", to you too!");
    return input;
  }
  // Standard JWS annotation to expose method "echoStruct" as a public operation
  // called "echoComplexType"
  // The WebResult annotation specifies that the name of the result of the
  // operation in the generated WSDL is "EchoStructReturnMessage",
  // rather than the default name "return".
  @WebMethod(operationName="echoComplexType")
  @WebResult(name="EchoStructReturnMessage",
    targetNamespace="http://example.org/complex")
  public BasicStruct echoStruct(BasicStruct struct)
  {
    System.out.println("echoComplexType called");
    return struct;
  }
}

2.2.3 Sample Ant Build File for ComplexImpl.java JWS File

The following build.xml file uses properties to simplify the file.
<project name="webservices-complex" default="all">
<!-- set global properties for this build -->
<property name="wls.username" value="weblogic" />
<property name="wls.password" value="weblogic" />
<property name="wls.hostname" value="localhost" />
<property name="wls.port" value="7001" />
<property name="wls.server.name" value="myserver" />
<property name="ear.deployed.name" value="complexServiceEAR" />
<property name="example-output" value="output" />
<property name="clientclass-dir" value="${example-output}/clientclass" />
<path id="client.class.path">
  <pathelement path="${clientclass-dir}"/>
  <pathelement path="${java.class.path}"/>
</path>
<taskdef name="jwsc"
  classname="weblogic.wsee.tools.anttasks.JwscTask" />
<taskdef name="clientgen"
  classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
<taskdef name="wldeploy"
  classname="weblogic.ant.taskdefs.management.WLDeploy" />
<target name="all" depends="clean,build-service,deploy,client"/>
<target name="clean" depends="undeploy">
  <delete dir="${example-output}"/>
</target>
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="${ear-dir}"
    keepGenerated="true"
  >
    <jws file="examples/webservices/complex/ComplexImpl.java"
      type="JAXRPC">
      <WLHttpTransport
        contextPath="complex" serviceUri="ComplexService"
        portName="ComplexServicePort"/>
    </jws>
  </jwsc>
</target>
<target name="deploy">
  <wldeploy action="deploy"
    name="${ear.deployed.name}"
    source="${ear-dir}" user="${wls.username}" password="${wls.password}"
    adminurl="t3://${wls.hostname}:${wls.port}" verbose="true"
    targets="${wls.server.name}"/>
</target>
<target name="undeploy">
  <wldeploy action="undeploy" failonerror="false"
    name="${ear.deployed.name}"
    user="${wls.username}" password="${wls.password}" verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}"/>
</target>
<target name="client">
  <clientgen
    wsdI="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="${clientclass-dir}"
    packageName="examples.webservices.complex.client"
    type="JAXRPC"/>
</target>
</project>
2.3 Creating a Web Service from a WSDL File

Another common use case of creating a web service is to start from an existing WSDL file, often referred to as the golden WSDL. A WSDL file is a public contract that specifies what the web service looks like, such as the list of supported operations, the signature and shape of each operation, the protocols and transports that can be used when invoking the operations, and the XML Schema data types that are used when transporting the data. Based on this WSDL file, you generate the artifacts that implement the web service so that it can be deployed to WebLogic Server. You use the wsdlc Ant task to generate the following artifacts.

- JWS service endpoint interface (SEI) that implements the web service described by the WSDL file.
- JWS implementation file that contains a partial (stubbed-out) implementation of the generated JWS SEI. This file must be customized by the developer.
- Data binding artifacts used by WebLogic Server to convert between the XML and Java representations of the web service parameters and return values.
- Optional Javadocs for the generated JWS SEI.

Note: The only file generated by the wsdlc Ant task that you update is the JWS implementation file. You never need to update the JAR file that contains the JWS SEI and data binding artifacts.

Typically, you run the wsdlc Ant task one time to generate a JAR file that contains the generated JWS SEI file and data binding artifacts, then code the generated JWS file that implements the interface, adding the business logic of your web service. In particular, you add Java code to the methods that implement the web service operations so that the operations behave as needed and add additional JWS annotations.

After you have coded the JWS implementation file, you run the jwsc Ant task to generate the deployable web service, using the same steps as described in the preceding sections. The only difference is that you use the compiledWsdl attribute to specify the JAR file (containing the JWS SEI file and data binding artifacts) generated by the wsdlc Ant task.
The following simple example shows how to create a web service from the WSDL file shown in Section 2.3.1, "Sample WSDL File." The web service has one operation, getTemp, that returns a temperature when passed a zip code.

1. Set your WebLogic Server environment.

Open a command window and execute the `setDomainEnv.cmd` (Windows) or `setDomainEnv.sh` (UNIX) script, located in the `bin` subdirectory of your domain directory. The default location of WebLogic Server domains is `ORACLE_HOME/user_projects/domains/domainName`, where `ORACLE_HOME` is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and `domainName` is the name of your domain.

2. Create a working directory:

   ```prompt> mkdir /myExamples/wsdlc```

3. Put your WSDL file into an accessible directory on your computer.

For the purposes of this example, it is assumed that your WSDL file is called `TemperatureService.wsdl` and is located in the `/myExamples/wsdlc/wsdl_files` directory. See Section 2.3.1, "Sample WSDL File" for a full listing of the file.

4. Create a standard Ant `build.xml` file in the project directory and add a `taskdef` Ant task to specify the full Java classname of the `wsdlc` task:

   ```xml
   <project name="webservices-wsdlc" default="all">
   <taskdef name="wsdlc" classname="weblogic.wsee.tools.anttasks.WsdlcTask"/>
   </project>
   ```

   See Section 2.3.3, "Sample Ant Build File for TemperatureService" for a full sample build.xml file that contains additional targets from those described in this procedure, such as `clean`, `undeploy`, `client`, and `run`. The full build.xml file also uses properties, such as `${ear-dir}`, rather than always using the hard-coded name for the EAR directory.

5. Add the following call to the `wsdlc` Ant task to the `build.xml` file, wrapped inside of the `generate-from-wsdl` target:

   ```xml
   <target name="generate-from-wsdl">
   <wsdlc
     srcWsdl="wsdl_files/TemperatureService.wsdl"
     destJwsDir="output/compiledWsdl"
     destImplDir="output/impl"
     packageName="examples.webservices.wsdlc" />
   </target>
   ```

   The `wsdlc` task in the examples generates the JAR file that contains the JWS SEI and data binding artifacts into the `output/compiledWsdl` directory under the current directory. It also generates a partial implementation file (`TemperaturePortTypeImpl.java`) of the JWS SEI into the `output/impl/examples/webservices/wsdlc` directory (which is a combination of the output directory specified by `destImplDir` and the directory hierarchy specified by the package name). All generated JWS files will be packaged in the `examples.webservices.wsdlc` package.

6. Execute the `wsdlc` Ant task by specifying the `generate-from-wsdl` target at the command line:

   ```prompt> ant generate-from-wsdl```
See the output directory if you want to examine the artifacts and files generated by the wsdlc Ant task.

7. Update the generated

output/impl/examples/webservices/wsdlc/TemperaturePortTypeImpl.java

JWS implementation file using your favorite Java IDE or text editor to add Java code to the methods so that they behave as you want.

See Section 2.3.2, "Sample TemperaturePortType Java Implementation File" for an example; the added Java code is in **bold**. The generated JWS implementation file automatically includes values for the @WebService and @WLHttpTransport JWS annotations that correspond to the values in the original WSDL file.

---

**Note:** There are restrictions on the JWS annotations that you can add to the JWS implementation file in the "starting from WSDL" use case. See "wsdlc" in the WebLogic Web Services Reference for Oracle WebLogic Server for details.

---

For simplicity, the sample `getTemp()` method in TemperaturePortTypeImpl.java returns a hard-coded number. In real life, the implementation of this method would actually look up the current temperature at the given zip code.

8. Copy the updated `TemperaturePortTypeImpl.java` file into a permanent directory, such as a src directory under the project directory; remember to create child directories that correspond to the package name:

```
prompt> cd /examples/wsdlc
prompt> mkdir src/examples/webservices/wsdlc
prompt> cp output/impl/examples/webservices/wsdlc/TemperaturePortTypeImpl.java
  src/examples/webservices/wsdlc/TemperaturePortTypeImpl.java
```

9. Add a build-service target to the build.xml file that executes the jwsc Ant task against the updated JWS implementation class. Use the compiledWsdl attribute of jwsc to specify the name of the JAR file generated by the wsdlc Ant task:

```
<taskdef name="jwsc"
  class="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="$\{ear-dir}\">
    <jws file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java"
         compiledWsdl="$(compiledWsdl-dir)/TemperatureService.wsdl.jar"
         type="JAXRPC">
      <WLHttpTransport
        contextPath="temp" serviceUri="TemperatureService"
        portName="TemperaturePort">
      </WLHttpTransport>
    </jws>
  </jwsc>
</target>
```

In the preceding example:

- The type attribute of the `<jws>` element specifies the type of web services (JAX-WS or JAX-RPC).
The `<WLHttpTransport>` child element of the `<jws>` element of the jwsc Ant task specifies the context path and service URI sections of the URL used to invoke the web service over the HTTP/S transport, as well as the name of the port in the generated WSDL. This value overrides the value specified in the JWS file using the `@WLHttpTransport` attribute.

10. Execute the `build-service` target to generate a deployable web service:

```
prompt> ant build-service
```

You can re-run this target if you want to update and then re-build the JWS file.

11. Start the WebLogic Server instance to which the web service will be deployed.

12. Deploy the web service, packaged in an Enterprise Application, to WebLogic Server, using either the WebLogic Server Administration Console or the `wldeploy` Ant task. In either case, you deploy the `wsdlcEar` Enterprise application, located in the output directory.

To use the `wldeploy` Ant task, add the following target to the `build.xml` file:

```
<taskdef name="wldeploy"
  classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="deploy">
  <wldeploy action="deploy" name="wsdlcEar"
    source="output/wsdlcEar" user="${wls.username}" password="${wls.password}" verbose="true"
    adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
</target>
```

Substitute the values for `wls.username`, `wls.password`, `wls.hostname`, `wls.port`, and `wls.server.name` that correspond to your WebLogic Server instance.

Deploy the WAR file by executing the `deploy` target:

```
prompt> ant deploy
```

13. Test that the web service is deployed correctly by invoking its WSDL in your browser:

```
http://host:port/temp/TemperatureService?WSDL
```

The context path and service URI section of the preceding URL are specified by the original golden WSDL. Use the hostname and port relevant to your WebLogic Server instance. Note that the deployed and original WSDL files are the same, except for the host and port of the endpoint address.

You can use the `clean`, `build-service`, `undeploy`, and `deploy` targets in the `build.xml` file to iteratively update, rebuild, undeploy, and redeploy the web service as part of your development process.

To run the web service, you need to create a client that invokes it. See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a web service.

### 2.3.1 Sample WSDL File

```
<?xml version="1.0"?>
<definitions
  name="TemperatureService"
  targetNamespace="http://www.xmethods.net/sd/TemperatureService.wsdl"
```
<message name="getTempRequest">
    <part name="zip" type="xsd:string"/>
</message>
<message name="getTempResponse">
    <part name="return" type="xsd:float"/>
</message>

<portType name="TemperaturePortType">
    <operation name="getTemp">
        <input message="tns:getTempRequest"/>
        <output message="tns:getTempResponse"/>
    </operation>
</portType>

<binding name="TemperatureBinding" type="tns:TemperaturePortType">
    <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http" />
    <operation name="getTemp">
        <soap:operation soapAction="" />
        <input>
            <soap:body use="literal" namespace="urn:xmethods-Temperature" />
        </input>
        <output>
            <soap:body use="literal" namespace="urn:xmethods-Temperature" />
        </output>
    </operation>
</binding>

<service name="TemperatureService">
    <documentation>
        Returns current temperature in a given U.S. zipcode
    </documentation>
    <port name="TemperaturePort" binding="tns:TemperatureBinding">
        <soap:address location="http://localhost:7001/temp/TemperatureService"/>
    </port>
</service>
</definitions>

2.3.2 Sample TemperaturePortType Java Implementation File

```java
package examples.webservices.wsdlic;
import javax.jws.WebService;
import weblogic.jws.*;
/**
 * TemperaturePortTypeImpl class implements web service endpoint
 * interface TemperaturePortType */
@WebService(
    serviceName="TemperatureService",
    targetNamespace="http://www.xmethods.net/sd/TemperatureService.wsdl"
)
@WLHttpTransport(
    contextPath="temp",
    serviceUri="TemperatureService",
    portName="TemperaturePort")
```
public class TemperaturePortTypeImpl implements examples.webservices.wsdlc.TemperaturePortType {
    public TemperaturePortTypeImpl() { }
    public float getTemp(java.lang.String zip) {
        return 1.234f;
    }
}

### 2.3.3 Sample Ant Build File for TemperatureService

The following build.xml file uses properties to simplify the file.

```xml
<project default="all">
    <!-- set global properties for this build -->
    <property name="wls.username" value="weblogic" />
    <property name="wls.password" value="weblogic" />
    <property name="wls.hostname" value="localhost" />
    <property name="wls.port" value="7001" />
    <property name="wls.server.name" value="myserver" />
    <property name="ear.deployed.name" value="wsdlcEar" />
    <property name="example-output" value="output" />
    <property name="compiledWsdl-dir" value="${example-output}/compiledWsdl" />
    <property name="impl-dir" value="${example-output}/impl" />
    <property name="ear-dir" value="${example-output}/wsdlcEar" />
    <property name="clientclass-dir" value="${example-output}/clientclasses" />
    <path id="client.class.path">
        <pathelement path="${clientclass-dir}"/>
        <pathelement path="${java.class.path}"/>
    </path>
    <taskdef name="wsdlc"
        classname="weblogic.wsee.tools.anttasks.WsdlcTask"/>
    <taskdef name="jwsc"
        classname="weblogic.wsee.tools.anttasks.JwscTask" />
    <taskdef name="clientgen"
        classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
    <taskdef name="wldeploy"
        classname="weblogic.ant.taskdefs.management.WLDeploy" />
    <target name="all"
        depends="clean,generate-from-wsdl,build-service,deploy,client" />
    <target name="clean"
        depends="undeploy">
        <delete dir="${example-output}"/>
    </target>
    <target name="generate-from-wsdl">
        <wsdlc
            srcWsdl="wsdl_files/TemperatureService.wsdl"
            destJwsDir="${compiledWsdl-dir}"
            destImplDir="${impl-dir}"
            packageName="examples.webservices.wsdlc"/>
    </target>
    <target name="build-service">
        <jwsc
            srcdir="src"
            destdir="${ear-dir}"/>
        <jws file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java"
            compiledWsdl="${compiledWsdl-dir}/TemperatureService.wsdl.jar"
            type="JAXRPC">
            <WLHttpTransport
                contextPath="temp" serviceUri="TemperatureService" portName="TemperaturePort"/>
```
2.4 Invoking a Web Service from a Java SE Client

**Note:** As described in this section, you can invoke a web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for stand-alone Java applications that are running in an environment where WebLogic Server libraries are not available, see Section 6.4, "Using a Standalone Client JAR File When Invoking Web Services".

When you invoke an operation of a deployed web service from a client application, the web service could be deployed to WebLogic Server or to any other application server, such as .NET. All you need to know is the URL to its public contract file, or WSDL.
In addition to writing the Java client application, you must also run the clientgen WebLogic web service Ant task to generate the artifacts that your client application needs to invoke the web service operation. These artifacts include:

- The Java class for the JAX-RPC Stub and Service interface implementations for the particular web service you want to invoke.
- The Java class for any user-defined XML Schema data types included in the WSDL file.
- The JAX-RPC mapping deployment descriptor file which contains information about the mapping between the Java user-defined data types and their corresponding XML Schema types in the WSDL file.
- A client-side copy of the WSDL file.

The following example shows how to create a Java client application that invokes the echoComplexType operation of the ComplexService WebLogic web service described in Section 2.2, "Creating a Web Service With User-Defined Data Types." The echoComplexType operation takes as both a parameter and return type the BasicStruct user-defined data type.

**Note:** It is assumed in this procedure that you have created and deployed the ComplexService web service.

1. Set your WebLogic Server environment.
   
   Open a command window and execute the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is $ORACLE_HOME/user_projects/domains/domainName, where $ORACLE_HOME is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and $domainName is the name of your domain.

2. Create a project directory:
   
   prompt> mkdir /myExamples/simple_client

3. Create a src directory under the project directory, as well as subdirectories that correspond to the package name of the Java client application (shown later on in this procedure):
   
   prompt> cd /myExamples/simple_client
   prompt> mkdir src/examples/webservices/simple_client

4. Create a standard Ant build.xml file in the project directory and add a taskdef Ant task to specify the full Java classname of the clientgen task:

   <project name="webservices-simple_client" default="all">
   <taskdef name="clientgen" class="weblogic.wsee.tools.anttasks.ClientGenTask" />
   </project>

   See Section 2.4.2, "Sample Ant Build File For Building Java Client Application" for a full sample build.xml file. The full build.xml file uses properties, such as $(clientclass-dir), rather than always using the hard-coded name output directory for client classes.

5. Add the following calls to the clientgen and javac Ant tasks to the build.xml file, wrapped inside of the build-client target:
<target name="build-client">
  <clientgen
    wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="output/clientclass"
    packageName="examples.webservices.simple_client"
    type="JAXRPC"/>
  <javac
    srcdir="output/clientclass" destdir="output/clientclass"
    includes="**/*.java"/>
  <javac
    srcdir="src" destdir="output/clientclass"
    includes="examples/webservices/simple_client/*.java"/>
</target>

The clientgen Ant task uses the WSDL of the deployed ComplexService web service to generate the necessary artifacts and puts them into the output/clientclass directory, using the specified package name. Replace the variables with the actual hostname and port of your WebLogic Server instance that is hosting the web service.

The clientgen Ant task also automatically generates the examples.webservices.complex.BasicStruct JavaBean class, which is the Java representation of the user-defined data type specified in the WSDL.

The build-client target also specifies the standard javac Ant task, in addition to clientgen, to compile all the Java code, including the simple Java program described in the next step, into class files.

The clientgen Ant task also provides the destFile attribute if you want the Ant task to automatically compile the generated Java code and package all artifacts into a JAR file. For details and an example, see "clientgen" in the WebLogic Web Services Reference for Oracle WebLogic Server.

6. Create the Java client application file that invokes the echoComplexType operation.

Open your favorite Java IDE or text editor and create a Java file called Main.java using the code specified in Section 2.4.1, "Sample Java Client Application."

The Main client application takes a single argument: the WSDL URL of the web service. The application then follows standard JAX-RPC guidelines to invoke an operation of the web service using the web service-specific implementation of the Service interface generated by clientgen. The application also imports and uses the BasicStruct user-defined type, generated by the clientgen Ant task, that is used as a parameter and return value for the echoStruct operation. For details, see Chapter 6, "Developing JAX-RPC Web Service Clients."

7. Save the Main.java file in the src/examples/webservices/simple_client subdirectory of the main project directory.

8. Execute the clientgen and javac Ant tasks by specifying the build-client target at the command line:

prompt> ant build-client

See the output/clientclass directory to view the files and artifacts generated by the clientgen Ant task.

9. Add the following targets to the build.xml file, used to execute the Main application:

<path id="client.class.path">
<target name="run">
  <java fork="true">
    <classpath refid="client.class.path"/>
    <arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService"/>
  </java>
</target>

The run target invokes the Main application, passing it the WSDL URL of the deployed web service as its single argument. The classpath element adds the clientclass directory to the CLASSPATH, using the reference created with the <path> task.

10. Execute the run target to invoke the echoComplexType operation:

    prompt> ant run

If the invoke was successful, you should see the following final output:

    run:
      [java] echoComplexType called. Result: 999, Hello Struct

You can use the build-client and run targets in the build.xml file to iteratively update, rebuild, and run the Java client application as part of your development process.

2.4.1 Sample Java Client Application

The following provides a simple Java client application that invokes the echoComplexType operation.

```java
package examples.webservices.simple_client;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
// import the BasicStruct class, used as a param and return value of the
// echoComplexType operation. The class is generated automatically by
// the clientgen Ant task.
import examples.webservices.complex.BasicStruct;
/**
 * This is a simple Java client application that invokes the
 * echoComplexType operation of the ComplexService web service.
 */
public class Main {
  public static void main(String[] args)
    throws ServiceException, RemoteException {
    ComplexService service = new ComplexService_Impl(args[0] + "?WSDL");
    ComplexPortType port = service.getComplexServicePort();
    BasicStruct in = new BasicStruct();
    in.setIntValue(999);
    in.setStringValue("Hello Struct");
    BasicStruct result = port.echoComplexType(in);
    System.out.println("echoComplexType called. Result: "+ result.getIntValue()
+ ", " + result.getStringValue());
  }
}
```
**2.4.2 Sample Ant Build File For Building Java Client Application**

The following `build.xml` file defines tasks to build the Java client application. The example uses properties to simplify the file.

```xml
<project name="webservices-simple_client" default="all">
  <!-- set global properties for this build -->
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="example-output" value="output" />
  <property name="clientclass-dir" value="${example-output}/clientclass" />
  <property name="client.class.path">
    <pathelement path="${clientclass-dir}" />
    <pathelement path="${java.class.path}" />
  </property>
  <taskdef name="clientgen"classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
  <target name="clean">
    <delete dir="${clientclass-dir}" />
  </target>
  <target name="all" depends="clean,build-client,run" />
  <target name="build-client">
    <clientgen type="JAXRPC"
      wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
      destDir="${clientclass-dir}"packageName="examples.webservices.simple_client"/>
    <javac srcdir="${clientclass-dir}" destdir="${clientclass-dir}"
      includes="**/*.java" />
    <javac srcdir="src" destdir="${clientclass-dir}"
      includes="examples/webservices/simple_client/*.java" />
  </target>
  <target name="run">
    <java fork="true"
      classname="examples.webservices.simple_client.Main"
      failonerror="true" >
      <classpath refid="client.class.path" />
      <arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService" />
    </java>
  </target>
</project>
```

**2.5 Invoking a Web Service from a WebLogic Web Service**

You can also invoke a web service (WebLogic, .NET, and so on) from within a deployed WebLogic web service.

The procedure for invoking a web service from a WebLogic web service is similar to that described in Section 2.4, "Invoking a Web Service from a Java SE Client" except that instead of running the `clientgen` Ant task to generate the client stubs, you use the `clientgen` child element of `<jws>`, inside of the `<jwsc>` Ant task. The `<jwsc>` Ant task automatically packages the generated client stubs in the invoking web service WAR file so that the web service has immediate access to them. You then follow standard JAX-RPC programming guidelines in the JWS file that implements the web service that invokes the other web service.
The following example shows how to write a JWS file that invokes the echoComplexType operation of the ComplexService web service described in Section 2.2, "Creating a Web Service With User-Defined Data Types."

**Note:** It is assumed that you have successfully deployed the ComplexService web service.

1. Set your WebLogic Server environment.
   
   Open a command window and execute the setDomainEnv.cmd (Windows) or setDomainEnv.sh (UNIX) script, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is ORACLE_HOME/user_projects/domains/domainName, where ORACLE_HOME is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and domainName is the name of your domain.

2. Create a project directory:
   
   ```
   prompt> mkdir /myExamples/service_to_service
   ```

3. Create a src directory under the project directory, as well as subdirectories that correspond to the package name of the JWS and client application files (shown later on in this procedure):
   
   ```
   prompt> cd /myExamples/service_to_service
   prompt> mkdir src/examples/webservices/service_to_service
   ```

4. Create the JWS file that implements the web service that invokes the ComplexService web service.
   
   Open your favorite Java IDE or text editor and create a Java file called ClientServiceImpl.java using the Java code specified in Section 2.5.1, "Sample ClientServiceImpl.java JWS File."

   The sample JWS file shows a Java class called ClientServiceImpl that contains a single public method, callComplexService(). The Java class imports the JAX-RPC stubs, generated later on by the jwsc Ant task, as well as the BasicStruct Java Bean (also generated by clientgen), which is the data type of the parameter and return value of the echoComplexType operation of the ComplexService web service.

   The ClientServiceImpl Java class defines one method, callComplexService(), which takes two parameters: a BasicStruct which is passed on to the echoComplexType operation of the ComplexService web service, and the URL of the ComplexService web service. The method then uses the standard JAX-RPC APIs to get the Service and PortType of the ComplexService, using the stubs generated by jwsc, and then invokes the echoComplexType operation.

5. Save the ClientServiceImpl.java file in the src/examples/webservices/service_to_service directory.

6. Create a standard Ant build.xml file in the project directory and add the following task:

   ```
   <project name="webservices-service_to_service" default="all">
   <taskdef name="jwsc" class="weblogic.wsee.tools.anttasks.JwscTask" />
   </project>
   ```

   The taskdef task defines the full classname of the jwsc Ant task.
See Section 2.5.2, "Sample Ant Build File For Building ClientService" for a full sample build.xml file that contains additional targets from those described in this procedure, such as clean, deploy, undeploy, client, and run. The full build.xml file also uses properties, such as ${ear-dir}, rather than always using the hard-coded name for the EAR directory.

7. Add the following call to the jwsc Ant task to the build.xml file, wrapped inside of the build-service target:

```xml
<target name="build-service">
    <jwsc srcdir="src" destdir="output/ClientServiceEar">
        <jws file="examples/webservices/service_to_service/ClientServiceImpl.java" type="JAXRPC">
            <WLHttpTransport contextPath="ClientService" serviceUri="ClientService" portName="ClientServicePort"/>
            <clientgen type="JAXRPC" wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL" packageName="examples.webservices.complex"/>
        </jws>
    </jwsc>
</target>
```

In the preceding example, the <clientgen> child element of the <jws> element of the jwsc Ant task specifies that, in addition to compiling the JWS file, jwsc should also generate and compile the client artifacts needed to invoke the web service described by the WSDL file.

In this example, the package name is set to examples.webservices.complex, which is different from the client application package name, examples.webservices.simple_client. As a result, you need to import the appropriate class files in the client application:

```java
import examples.webservices.complex.BasicStruct;
import examples.webservices.complex.ComplexPortType;
import examples.webservices.complex.ComplexService;
```

If the package name is set to the same package name as the client application, the import calls would be optional.

8. Execute the jwsc Ant task by specifying the build-service target at the command line:

```shell
prompt> ant build-service
```

9. Start the WebLogic Server instance to which you will deploy the web service.

10. Deploy the web service, packaged in an enterprise application, to WebLogic Server, using either the WebLogic Server Administration Console or the wldeploy Ant task. In either case, you deploy the ClientServiceEar Enterprise application, located in the output directory.

To use the wldeploy Ant task, add the following target to the build.xml file:

```xml
<taskdef name="wldeploy" classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="deploy">
    <wldeploy action="deploy" name="ClientServiceEar"/>
</target>
```
Substitute the values for `wls.username`, `wls.password`, `wls.hostname`, `wls.port`, and `wls.server.name` that correspond to your WebLogic Server instance.

Deploy the WAR file by executing the `deploy` target:

```
prompt> ant deploy
```

11. Test that the web service is deployed correctly by invoking its WSDL in your browser:

```
http://host:port/ClientService/ClientService?WSDL
```

See Section 2.4, "Invoking a Web Service from a Java SE Client" for an example of creating a Java client application that invokes a web service.

### 2.5.1 Sample ClientServiceImpl.java JWS File

The following provides a simple web service client application that invokes the `echoComplexType` operation.

```java
package examples.webservices.service_to_service;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;
// Import the BasicStruct data type, generated by clientgen and used
// by the ComplexService Web Service
import examples.webservices.complex.BasicStruct;
// Import the JAX-RPC Stubs for invoking the ComplexService Web Service.
// Stubs generated by clientgen
import examples.webservices.service_to_service.ComplexPortType;
import examples.webservices.service_to_service.ComplexService_Impl;
import examples.webservices.service_to_service.ComplexService;
@WebService(name="ClientPortType", serviceName="ClientService",
targetNamespace="http://examples.org")
@WLHttpTransport(contextPath="ClientService", serviceUri="ClientService",
portName="ClientServicePort")
public class ClientServiceImpl {
    @WebMethod()
    public String callComplexService(BasicStruct input, String serviceUrl)
        throws ServiceException, RemoteException
    {
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePort();
        // Invoke the echoComplexType operation of ComplexService
        BasicStruct result = port.echoComplexType(input);
        System.out.println("Invoked ComplexPortType.echoComplexType.");
        return "Invoke went okay! Here's the result: " + result.getIntValue() + ",
        " + result.getStringValue() + ";
    }
}
```
2.5.2 Sample Ant Build File For Building ClientService

The following build.xml file defines tasks to build the client application. The example uses properties to simplify the file.

The following build.xml file uses properties to simplify the file.

```xml
<project name="webservices-service_to_service" default="all">
  <!-- set global properties for this build -->
  <property name="wls.username" value="weblogic" />
  <property name="wls.password" value="weblogic" />
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="wls.server.name" value="myserver" />
  <property name="ear.deployed.name" value="ClientServiceEar" />
  <property name="example-output" value="output" />
  <property name="ear-dir" value="${example-output}/ClientServiceEar" />
  <property name="clientclass-dir" value="${example-output}/clientclasses" />
  <property name="client.class.path" value="${clientclass-dir}" />
  <property name="java.class.path" value="${java.class.path}" />
</project>

<taskdef name="jwsc" classname="weblogic.wsee.tools.anttasks.JwscTask" />
<taskdef name="clientgen" classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
<taskdef name="wldeploy" classname="weblogic.ant.taskdefs.management.WLDeploy"/>
<target name="all" depends="clean,build-service,deploy,client" />
<target name="clean" depends="undeploy">
  <delete dir="${example-output}" />
</target>
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="${ear-dir}" >
    <jws
      file="examples/webservices/service_to_service/ClientServiceImpl.java"
      type="JAXRPC">
      <WLHttpTransport
        contextPath="ClientService" serviceUri="ClientService"
        portName="ClientServicePort"/>
      <clientgen
        type="JAXRPC"
        wadl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
        packageName="examples.webservices.complex" />
    </jws>
  </jwsc>
</target>
<target name="deploy">
  <wldeploy action="deploy" name="${ear.deployed.name}" source="${ear-dir}" user="${wls.username}" password="${wls.password}" verbose="true" adminurl="t3://${wls.hostname}:${wls.port}" targets="${wls.server.name}" />
</target>
<target name="undeploy">
  <wldeploy action="undeploy" name="${ear.deployed.name}" failonerror="false" user="${wls.username}" password="${wls.password}" verbose="true" />
</target>
```

Examples for JAX-RPC Web Service Developers  2-25
adminurl="t3://${wls.hostname}:${wls.port}"
    targets="${wls.server.name}" />
</target>
<target name="client">
    <clientgen
        wsdl="http://${wls.hostname}:${wls.port}/ClientService/ClientService?WSDL"
        destDir="${clientclass-dir}"
        packageName="examples.webservices.service_to_service.client"
        type="JAXRPC"/>
    <javac
        srcdir="${clientclass-dir}" destdir="${clientclass-dir}"
        includes="**/*.java"/>
    <javac
        srcdir="src" destdir="${clientclass-dir}"
        includes="examples/webservices/service_to_service/client/**/*.java"/>
</target>
<target name="run">
    <java classname="examples.webservices.service_to_service.client.Main"
        fork="true"
        failonerror='true' >
        <classpath refid="client.class.path"/>
        <arg
            line="http://${wls.hostname}:${wls.port}/ClientService/ClientService"/>
    </java>
</target>
</project>
Part II describes how to develop basic WebLogic web services using Java API for XML-based RPC (JAX-RPC).

Sections include:

- Chapter 3, "Developing JAX-RPC Web Services"
- Chapter 4, "Programming the JWS File"
- Chapter 5, "Understanding Data Binding"
This chapter describes the iterative development process for WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following sections:

- Overview of the WebLogic Web Service Programming Model
- Configuring Your Domain For Web Services Features
- Developing WebLogic Web Services Starting From Java: Main Steps
- Developing WebLogic Web Services Starting From a WSDL File: Main Steps
- Creating the Basic Ant build.xml File
- Running the jwsc WebLogic Web Services Ant Task
- Running the wsdlc WebLogic Web Services Ant Task
- Updating the Stubbed-out JWS Implementation Class File Generated By wsdlc
- Deploying and Undeploying WebLogic Web Services
- Browsing to the WSDL of the Web Service
- Configuring the Server Address Specified in the Dynamic WSDL
- Testing the Web Service
- Integrating Web Services Into the WebLogic Split Development Directory Environment

### 3.1 Overview of the WebLogic Web Service Programming Model

The WebLogic Web Services programming model centers around JWS files—Java files that use JWS annotations to specify the shape and behavior of the Web Service—and Ant tasks that execute on the JWS file. JWS annotations are based on the metadata feature, introduced in Version 5.0 of the JDK (specified by JSR-175 at http://www.jcp.org/en/jsr/detail?id=175) and include standard annotations defined by Web Services Metadata for the Java Platform specification (JSR-181), described at http://www.jcp.org/en/jsr/detail?id=181, as well as additional ones. For a complete list of JWS annotations that are supported, see "Web Service Annotation Support" in WebLogic Web Services Reference for Oracle WebLogic Server. For additional detailed information about this programming model, see Understanding WebLogic Web Services for Oracle WebLogic Server.

The following sections describe the high-level steps for iteratively developing a Web Service, either starting from Java or starting from an existing WSDL file:
Iterative development refers to setting up your development environment in such a way so that you can repeatedly code, compile, package, deploy, and test a Web Service until it works as you want. The WebLogic Web Service programming model uses Ant tasks to perform most of the steps of the iterative development process. Typically, you create a single build.xml file that contains targets for all the steps, then repeatedly run the targets, after you have updated your JWS file with new Java code, to test that the updates work as you expect.

In addition to the command-line tools described in this section, you can use an IDE, such as Oracle JDeveloper, to develop web services. For more information, see "Using Oracle IDEs to Build Web Services" in Understanding WebLogic Web Services for Oracle WebLogic Server.

### 3.2 Configuring Your Domain For Web Services Features

After you have created a WebLogic Server domain, you can use the Configuration Wizard to update the domain, using a Web Services-specific extension template, so that the resources required by certain WebLogic Web Services features are automatically configured. Although use of this extension template is not required, it makes the configuration of JMS and JDBC resources much easier.

The Web Services extension template automatically configures the resources required for the following features:

- Web Services Reliable Messaging
- Buffering
- JMS Transport

**Note:** A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

The following procedures describe how to create and extend a domain so that it is automatically configured for the advanced web services features. For detailed instructions about using the Configuration Wizard to create and update WebLogic Server domains, see Creating WebLogic Domains Using the Configuration Wizard.

To create a domain that is automatically configured for the advanced web service features:

1. Start the Configuration Wizard.
2. In the Welcome window, select **Create a new WebLogic domain**.
3. Click **Next**.
4. Select **Generate a domain configured automatically to support the following products** and select **WebLogic Advanced Web Services for JAX-RPC Extension**.
5. Click **Next**.
6. Enter the name and location of the domain and click **Next**.
7. Configure the administrator user name and password and click **Next**.
8. Configure the server start mode and JDK and click **Next**.
9. If you want to further configure the JMS services, file stores, or any other feature, select the items on the Select Optional Configuration screen. This is not typical. Otherwise, leave all items deselected and click **Next**.
10. When you reach the Configuration Summary screen, verify the domain details and click **Create**.
11. Click **Done** to exit.

To extend an existing domain so that it is automatically configured for these Web Services features:

1. Start the Configuration Wizard.
2. In the Welcome window, select **Extend an Existing WebLogic Domain**.
3. Click **Next**.
4. Select the domain to which you want to apply the extension template.
5. Click **Next**.
6. Select **Extend my domain automatically to support the following added products** and select **WebLogic Advanced Web Services for JAX-RPC Extension**.
7. Click **Next**.
8. If you want to further configure the JMS services or file stores, select the items on the Select Optional Configuration screen. This is not typical. Otherwise, leave all items deselected and click **Next**.
9. Verify that you are extending the correct domain, then click **Extend**.
10. Click **Done** to exit.

### 3.3 Developing WebLogic Web Services Starting From Java: Main Steps

This section describes the general procedure for developing WebLogic Web Services starting from Java—in effect, coding the JWS file from scratch and later generating the WSDL file that describes the service. See Chapter 2, "Examples for JAX-RPC Web Service Developers" for specific examples of this process.

The following procedure is just a recommendation; if you have set up your own development environment, you can use this procedure as a guide for updating your existing environment to develop WebLogic Web Services.

---

**Note:** This procedure does not use the WebLogic Web Services split development directory environment. If you are using this development environment, and would like to integrate Web Services development into it, see Section 3.13, "Integrating Web Services Into the WebLogic Split Development Directory Environment" for details.
### 3.4 Developing WebLogic Web Services Starting From a WSDL File: Main Steps

This section describes the general procedure for developing WebLogic Web Services based on an existing WSDL file. See Chapter 3, “Developing JAX-RPC Web Services” for a specific example of this process.

#### Table 3-1  Steps to Develop Web Services Starting From Java

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set up the environment.</td>
<td>Open a command window and execute the <code>setDomainEnv.cmd</code> (Windows) or <code>setDomainEnv.sh</code> (UNIX) command, located in the <code>bin</code> subdirectory of your domain directory. The default location of WebLogic Server domains is <code>ORACLE_HOME/user_projects/domains/domainName</code>, where <code>ORACLE_HOME</code> is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and <code>domainName</code> is the name of your domain.</td>
</tr>
<tr>
<td>2</td>
<td>Create a project directory.</td>
<td>The project directory will contain the JWS file, Java source for any user-defined data types, and the Ant <code>build.xml</code> file. You can name the project directory anything you want.</td>
</tr>
<tr>
<td>3</td>
<td>Create the JWS file that implements the Web Service.</td>
<td>See Section 4.3, “Programming the JWS File: Typical Steps.”</td>
</tr>
<tr>
<td>4</td>
<td>Create user-defined data types. (Optional)</td>
<td>If your Web Service uses user-defined data types, create the JavaBeans that describes them. See Section 4.6, “Programming the User-Defined Java Data Type.”</td>
</tr>
<tr>
<td>5</td>
<td>Create a basic Ant build file, <code>build.xml</code>.</td>
<td>See Section 3.5, “Creating the Basic Ant build.xml File.”</td>
</tr>
<tr>
<td>6</td>
<td>Run the <code>jwsc</code> Ant task against the JWS file.</td>
<td>The <code>jwsc</code> Ant task generates source code, data binding artifacts, deployment descriptors, and so on, into an output directory. The <code>jwsc</code> Ant task generates an Enterprise application directory structure at this output directory; later you deploy this exploded directory to WebLogic Server as part of the iterative development process. See Section 3.6, “Running the jwsc WebLogic Web Services Ant Task.”</td>
</tr>
<tr>
<td>7</td>
<td>Deploy the Web Service to WebLogic Server.</td>
<td>See Section 3.9, “Deploying and Undeploying WebLogic Web Services.”</td>
</tr>
<tr>
<td>8</td>
<td>Browse to the WSDL of the Web Service.</td>
<td>Browse to the WSDL of the Web Service to ensure that it was deployed correctly. See Section 3.10, “Browsing to the WSDL of the Web Service.”</td>
</tr>
<tr>
<td>9</td>
<td>Test the Web Service.</td>
<td>See Section 3.12, “Testing the Web Service.”</td>
</tr>
<tr>
<td>10</td>
<td>Edit the Web Service. (Optional)</td>
<td>To make changes to the Web Service, update the JWS file, undeploy the Web Service as described in Section 3.9, “Deploying and Undeploying WebLogic Web Services,” then repeat the steps starting from running the <code>jwsc</code> Ant task (Step 6).</td>
</tr>
</tbody>
</table>

See Chapter 4, “Programming the JWS File” for information on writing client applications that invoke a Web Service.
The procedure is just a recommendation; if you have set up your own development environment, you can use this procedure as a guide for updating your existing environment to develop WebLogic Web Services.

It is assumed in this procedure that you already have an existing WSDL file.

---

**Note:** This procedure does not use the WebLogic Web Services split development directory environment. If you are using this development environment, and would like to integrate Web Services development into it, see Section 3.13, "Integrating Web Services Into the WebLogic Split Development Directory Environment" for details.

---

### Table 3–2 Steps to Develop Web Services Starting From Java

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set up the environment.</td>
<td>Open a command window and execute the <code>setDomainEnv.cmd</code> (Windows) or <code>setDomainEnv.sh</code> (UNIX) command, located in the bin subdirectory of your domain directory. The default location of WebLogic Server domains is <code>ORACLE_HOME/user_projects/domains/domainName</code>, where <code>ORACLE_HOME</code> is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and <code>domainName</code> is the name of your domain.</td>
</tr>
<tr>
<td>2</td>
<td>Create a project directory.</td>
<td>The project directory will contain the generated artifacts and the Ant <code>build.xml</code> file.</td>
</tr>
<tr>
<td>3</td>
<td>Create a basic Ant build file, <code>build.xml</code>.</td>
<td>See Section 3.5, &quot;Creating the Basic Ant build.xml File.&quot;</td>
</tr>
<tr>
<td>4</td>
<td>Put your WSDL file in a directory that the <code>build.xml</code> Ant build file is able to read.</td>
<td>For example, you can put the WSDL file in a <code>wsdl_files</code> child directory of the project directory.</td>
</tr>
<tr>
<td>5</td>
<td>Run the <code>wsdlc</code> Ant task against the WSDL file.</td>
<td>The <code>wsdlc</code> Ant task generates the JWS service endpoint interface (SEI), the stubbed-out JWS class file, JavaBeans that represent the XML Schema data types, and so on, into output directories. See Section 3.7, &quot;Running the <code>wsdlc</code> WebLogic Web Services Ant Task.&quot;</td>
</tr>
<tr>
<td>6</td>
<td>Update the stubbed-out JWS file generated by the <code>wsdlc</code> Ant task.</td>
<td>The <code>wsdlc</code> Ant task generates a stubbed-out JWS file. You need to add your business code to the Web Service so it behaves as you want. See Section 3.8, &quot;Updating the Stubbed-out JWS Implementation Class File Generated By <code>wsdlc</code>.&quot;</td>
</tr>
<tr>
<td>7</td>
<td>Run the <code>jwsc</code> Ant task against the JWS file.</td>
<td>Specify the artifacts generated by the <code>wsdlc</code> Ant task as well as your updated JWS implementation file, to generate an Enterprise Application that implements the Web Service. See Section 3.6, &quot;Running the <code>jwsc</code> WebLogic Web Services Ant Task.&quot;</td>
</tr>
<tr>
<td>8</td>
<td>Deploy the Web Service to WebLogic Server.</td>
<td>See Section 3.9, &quot;Deploying and Undeploying WebLogic Web Services.&quot;</td>
</tr>
</tbody>
</table>
Creating the Basic Ant build.xml File

3.5 Creating the Basic Ant build.xml File

Ant uses build files written in XML (default name build.xml) that contain a <project> root element and one or more targets that specify different stages in the Web Services development process. Each target contains one or more tasks, or pieces of code that can be executed. This section describes how to create a basic Ant build file; later sections describe how to add targets to the build file that specify how to execute various stages of the Web Services development process, such as running the jwsc Ant task to process a JWS file and deploying the Web Service to WebLogic Server.

The following skeleton build.xml file specifies a default all target that calls all other targets that will be added in later sections:

```xml
<project default='all'>
  <target name='all'
    depends='clean,build-service,deploy' />
  <target name='clean'>
    <delete dir='output' />
  </target>
  <target name='build-service'>
    <!--add jwsc and related tasks here -->
  </target>
  <target name='deploy'>
    <!--add wldeploy task here -->
  </target>
</project>
```

See Chapter 6, "Developing JAX-RPC Web Service Clients" for information on writing client applications that invoke a Web Service.

### Table 3–2 (Cont.) Steps to Develop Web Services Starting From Java

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 9   | Browse to the WSDL of the Web Service.    | Browse to the WSDL of the Web Service to ensure that it was deployed correctly. See Section 3.10, "Browsing to the WSDL of the Web Service."

The URL used to invoke the WSDL of the deployed Web Service is essentially the same as the value of the location attribute of the <address> element in the original WSDL (except for the host and port values which now correspond to the host and port of the WebLogic Server instance to which you deployed the service.) This is because the wsdlc Ant task generated values for the contextPath and serviceURI of the @WLHttpTransport annotation in the JWS implementation file so that together they create the same URI as the endpoint address specified in the original WSDL.

| 10  | Test the Web Service.                     | See Section 3.12, "Testing the Web Service."                                |
| 11  | Edit the Web Service. (Optional)          | To make changes to the Web Service, update the JWS file, undeploy the Web Service as described in Section 3.9, "Deploying and Undeploying WebLogic Web Services," then repeat the steps starting from running the jwsc Ant task (Step 6). |
3.6 Running the jwsc WebLogic Web Services Ant Task

The jwsc Ant task takes as input a JWS file that contains JWS annotations and generates all the artifacts you need to create a WebLogic Web Service. The JWS file can be either one you coded yourself from scratch or one generated by the wsdlc Ant task. The jwsc-generated artifacts include:

- JSR-109 Web Service class file.

- All required deployment descriptors, including:
  - JAX-RPC mapping files.
  - Java class-implemented Web Services: web.xml and weblogic.xml.
  - Ear deployment descriptor files: application.xml and weblogic-application.xml.

- The XML Schema representation of any Java user-defined types used as parameters or return values to the Web Service operations.

- The WSDL file that publicly describes the Web Service.

If you are running the jwsc Ant task against a JWS file generated by the wsdlc Ant task, the jwsc task does not generate these artifacts, because the wsdlc Ant task already generated them for you and packaged them into a JAR file. In this case, you use an attribute of the jwsc Ant task to specify this wsdlc-generated JAR file.

After generating all the required artifacts, the jwsc Ant task compiles the Java files (including your JWS file), packages the compiled classes and generated artifacts into a deployable JAR archive file, and finally creates an exploded Enterprise Application directory that contains the JAR file.

You can use the jwsc Ant task to perform the following advanced tasks:

- Process multiple JWS files at once. You can choose to package each resulting Web Service into its own Web application WAR file, or group all of the Web Services into a single WAR file.

- Specify the transports (HTTP/HTTPS/JMS) that client applications can use when invoking the Web Service, possibly overriding any existing @WLXXXTransport annotations, as described in Chapter 3.6.1, "Specifying the Transport Used to Invoke the Web Service."

- Automatically generate the JAX-RPC client stubs of any other Web Service that is invoked within the JWS file.

- Update an existing Enterprise Application or Web application, rather than generate a completely new one.

To run the jwsc Ant task, add the following taskdef and build-service target to the build.xml file:

```xml
<taskdef name="jwsc"
  classname="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
  <jwsc
    srcdir="src_directory"
    destdir="ear_directory" />
```

Developing JAX-RPC Web Services  3-7
<jws file="JWS_file"
    compiledWsdl="WSDL_Generated_JAR"
    type="WebService_type"/>
</jwsc>
</target>

where:

- **ear_directory** refers to an Enterprise Application directory that will contain all the generated artifacts.
- **src_directory** refers to the top-level directory that contains subdirectories that correspond to the package name of your JWS file.
- **JWS_file** refers to the full pathname of your JWS file, relative to the value of the src_directory attribute.
- **WSDL_Generated_JAR** refers to the JAR file generated by the wsdlc Ant task that contains the JWS SEI and data binding artifacts that correspond to an existing WSDL file.

Note: You specify this attribute only in the "starting from WSDL" use case; this procedure is described in Section 3.4, "Developing WebLogic Web Services Starting From a WSDL File: Main Steps."

- **WebService_type** specifies the type of Web Service. This value can be set to JAXWS or JAXRPC.

The required taskdef element specifies the full class name of the jwsc Ant task.

Only the srcdir and destdir attributes of the jwsc Ant task are required. This means that, by default, it is assumed that Java files referenced by the JWS file (such as JavaBeans input parameters or user-defined exceptions) are in the same package as the JWS file. If this is not the case, use the sourcepath attribute to specify the top-level directory of these other Java files.

See "jwsc" in the WebLogic Web Services Reference for Oracle WebLogic Server for complete documentation and examples about the jwsc Ant task.

### 3.6.1 Specifying the Transport Used to Invoke the Web Service

The <jws> child element of jwsc includes the following optional child elements for specifying the transports (HTTP/S or JMS) that are used to invoke the web service:

- **WLHttpTransport**—Specifies the context path and service URI sections of the URL used to invoke the web service over the HTTP/S transport, as well as the name of the port in the generated WSDL.
- **WLJMSTransport**—Specifies the context path and service URI sections of the URL used to invoke the web service over the JMS transport, as well as the name of the port in the generated WSDL. You also specify the name of the JMS queue and connection factory that you have already configured for JMS transport.

The following guidelines describe the usage of the transport elements for the jwsc Ant task:

- The transports you specify to jwsc always override any corresponding transport annotations in the JWS file. In addition, all attributes of the transport annotation are ignored, even if you have not explicitly specified the corresponding attribute for
the transport element, in which case the default value of the transport element attribute is used.

- You can specify both transport elements for a particular JWS file. However, you can specify only one instance of a particular transport element. For example, although you cannot specify two different <WLHttpTransport> elements for a given JWS file, you can specify one <WLHttpTransport> and one <WLJmsTransport> element.

- The value of the serviceURI attribute can be the same when you specify both <WLJmsTransport> and <WLHttpTransport>.

- All transports associated with a particular JWS file must specify the same contextPath attribute value.

- If you specify more than one transport element for a particular JWS file, the value of the portName attribute for each element must be unique among all elements. This means that you must explicitly specify this attribute if you add more than one transport child element to <jws>, because the default value of the element will always be the same and thus cause an error when running the jwsc Ant task.

- If you do not specify any transport as either one of the transport elements to the jwsc Ant task or a transport annotation in the JWS file, then the web service’s default URL corresponds to the default value of the WLHttpTransport element.

For JAX-RPC web services, when you program your JWS file, you can use an annotation to specify the transport that clients use to invoke the web service, in particular @weblogic.jws.WLHttpTransport or @weblogic.jws.WLJmsTransport. You can specify only one instance of a particular transport annotation in the JWS file. For example, although you cannot specify two different @WLHttpTransport annotations, you can specify one @WLHttpTransport and one @WLJmsTransport annotation. However, you might not know at the time that you are coding the JWS file which transports best suits your needs. For this reason, it is often better to specify the transport at build-time.

### 3.6.2 Defining the Context Path of a WebLogic Web Service

There are a variety of places where the context path (also called context root) of a WebLogic web service can be specified. This section describes how to determine which is the true context path of the service based on its configuration, even if it is has been set in multiple places.

In the context of this discussion, a web service context path is the string that comes after the host:port portion of the web service URL. For example, if the deployed WSDL of a WebLogic web service is as follows:

The context path for this web service is financial.

The following list describes the order of precedence, from most to least important, of all possible context path specifications:

1. The contextPath attribute of the <module> element and <jws> element (when used as a direct child of the jwsc Ant task.)
2. The contextPath attribute of the <WLXXXTransport> child elements of <jws>.
3. The contextPath attribute of the @WLXXXTransport JWS annotations, as described in Section 4.3.4, "Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation)."
4. The default value of the context path, which is the name of the JWS file without any extension.

Suppose, for example, that you specified the @WLHttpTransport annotation in your JAX-RPC JWS file and set its contextPath attribute to financial. If you do not specify any additional contextPath attributes in the jwsc Ant task in your build.xml file, then the context path for this web service would be financial.

Assume that you then update the build.xml file and add a <WLHttpTransport> child element to the <jws> element that specifies the JWS file and set its contextPath attribute to finance. The context path of the web service would now be finance. If, however, you then group the <jws> element (including its child <WLHttpTransport> element) under a <module> element, and set its contextPath attribute to money, then the context path of the web service would now be money.

If you do not specify any contextPath attribute in either the JWS file or the jwsc Ant task, then the context path of the web service is the default value: the name of the JWS file without its *.java extension.

If you group two or more <jws> elements under a <module> element and do not set the context path using any of the other options listed above, then you must specify the contextPath attribute of <module> to specify the common context path used by all the web services in the module. Otherwise, the default context paths for all the web services in the module are going to be different (due to different names of the implementing JWS files), which is not allowed in a single WAR file.

3.6.3 Examples of Using jwsc

The following build.xml excerpt shows a basic example of running the jwsc Ant task on a JWS file:

```
<taskdef name="jwsc"  
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
<target name="build-service">
    <jwsc  
        srcdir="src"  
        destdir="output/helloWorldEar">  
        <jws  
            file="examples/webservices/hello_world/HelloWorldImpl.java"  
            type="JAXRPC"/>  
    </jwsc>
</target>
```

In the example:

- The Enterprise application will be generated, in exploded form, in output/helloWorldEar, relative to the current directory.
- The JWS file is called HelloWorldImpl.java, and is located in the src/examples/webservices/hello_world directory, relative to the current directory. This implies that the JWS file is in the package examples.webservices.helloWorld.
- A JAX-RPC Web Service is generated.

The following example is similar to the preceding one, except that it uses the compiledWsdl attribute to specify the JAR file that contains wsdlc-generated artifacts (for the “starting with WSDL” use case):

```
<taskdef name="jwsc"  
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
```
<target name="build-service">
  <jwsc
    srcdir="src"
    destdir="output/wsdlcEar">
    <jws
      file="examples/webservices/wsdlc/TemperaturePortTypeImpl.java"
      compiledWsdl="output/compiledWsdl/TemperatureService_wsdl.jar"
      type="JAXRPC"/>
  </jwsc>
</target>

In the preceding example, the TemperaturePortTypeImpl.java file is the stubbed-out JWS file that you updated to include your business logic. Because the compiledWsdl attribute is specified and points to a JAR file, the jwsc Ant task does not regenerate the artifacts that are included in the JAR.

To actually run this task, type at the command line the following:

prompt> ant build-service

### 3.7 Running the wsdlc WebLogic Web Services Ant Task

The wsdlc Ant task takes as input a WSDL file and generates artifacts that together partially implement a WebLogic Web Service. These artifacts include:

- JWS service endpoint interface (SEI) that implements the Web Service described by the WSDL file.
- JWS implementation file that contains a partial (stubbed-out) implementation of the generated JWS SEI. This file must be customized by the developer.
- Data binding artifacts used by WebLogic Server to convert between the XML and Java representations of the Web Service parameters and return values.
- Optional Javadocs for the generated JWS SEI.

The wsdlc Ant task packages the JWS SEI and data binding artifacts together into a JAR file that you later specify to the jwsc Ant task. You never need to update this JAR file; the only file you update is the JWS implementation class.

To run the wsdlc Ant task, add the following taskdef and generate-from-wsdl targets to the build.xml file:

```xml
<taskdef name="wsdlc"
  className="weblogic.wsee.tools.anttasks.WsdlcTask"/>
<target name="generate-from-wsdl">
  <wsdlc
    srcWsdl="WSDL_file"
    destJwsDir="JWS_interface_directory"
    destImplDir="JWS_implementation_directory"
    packageName="Package_name"
    type="WebService_type"/>
</target>
```

where:

- WSDL_file refers to the name of the WSDL file from which you want to generate a partial implementation, including its absolute or relative pathname.
- JWS_interface_directory refers to the directory into which the JAR file that contains the JWS SEI and data binding artifacts should be generated.
Running the wsdlc WebLogic Web Services Ant Task

The name of the generated JAR file is WSDLFile_wsdl.jar, where WSDLFile refers to the root name of the WSDL file. For example, if the name of the WSDL file you specify to the file attribute is MyService.wsdl, then the generated JAR file is MyService_wsdl.jar.

- **JWS_implementation_directory** refers to the top directory into which the stubbed-out JWS implementation file is generated. The file is generated into a subdirectory hierarchy corresponding to its package name.

  The name of the generated JWS file is PortTypeImpl.java, where PortType refers to the name attribute of the <portType> element in the WSDL file for which you are generating a Web Service. For example, if the port type name is MyServicePortType, then the JWS implementation file is called MyServicePortTypeImpl.java.

- **Package_name** refers to the package into which the generated JWS SEI and implementation files should be generated. If you do not specify this attribute, the wsdlc Ant task generates a package name based on the targetNamespace of the WSDL.

- **WebService_type** specifies the type of Web Service. This value can be set to JAXWS or JAXRPC.

The required taskdef element specifies the full class name of the wsdlc Ant task.

Only the srcWsdl and destJwsDir attributes of the wsdlc Ant task are required.

Typically, however, you generate the stubbed-out JWS file to make your programming easier. Oracle recommends you explicitly specify the package name in case the targetNamespace of the WSDL file is not suitable to be converted into a readable package name.

The following build.xml excerpt shows an example of running the wsdlc Ant task against a WSDL file:

```xml
<taskdef name="wsdlc"
    classname="weblogic.wsee.tools.anttasks.WsdlcTask"/>
<target name="generate-from-wsdl">
<wsdlc
    srcWsdl='wsdl_files/TemperatureService.wsdl'
    destJwsDir='output/compiledWsdl'
    destImplDir='impl_output'
    packageName='examples.webservices.wsdlc'
    type='JAXRPC' />
</target>
```

In the example:

- The existing WSDL file is called TemperatureService.wsdl and is located in the wsdl_files subdirectory of the directory that contains the build.xml file.

- The JAR file that will contain the JWS SEI and data binding artifacts is generated to the output/compiledWsdl directory; the name of the JAR file is TemperatureService_wsdl.jar.

- The package name of the generated JWS files is examples.webservices.wsdlc.

- The stubbed-out JWS file is generated into the impl_output/examples/webservices/wsdlc directory relative to the current directory.

- Assuming that the port type name in the WSDL file is TemperaturePortType, then the name of the JWS implementation file is TemperaturePortTypeImpl.java.

- A JAX-RPC Web Service is generated.
To actually run this task, type the following at the command line:

```prompt> ant generate-from-wsdl```

See "wsdlc" in WebLogic Web Services Reference for Oracle WebLogic Server for more information.

### 3.8 Updating the Stubbed-out JWS Implementation Class File Generated By wsdlc

The `wsdlc` Ant task generates the stubbed-out JWS implementation file into the directory specified by its `destImplDir` attribute; the name of the file is `PortTypeImpl.java`, where `PortType` is the name of the portType in the original WSDL. The class file includes everything you need to compile it into a Web Service, except for your own business logic.

The JWS class implements the JWS Web Service endpoint interface that corresponds to the WSDL file; the JWS SEI is also generated by `wsdlc` and is located in the JAR file that contains other artifacts, such as the Java representations of XML Schema data types in the WSDL and so on. The public methods of the JWS class correspond to the operations in the WSDL file.

The `wsdlc` Ant task automatically includes the `@WebService` and `@WLHttpTransport` annotations in the JWS implementation class; the values of the attributes corresponds to the equivalent values in the WSDL. For example, the `serviceName` attribute of `@WebService` is the same as the `name` attribute of the `<service>` element in the WSDL file; the `contextPath` and `serviceUri` attributes of `@WLHttpTransport` together make up the endpoint address specified by the `location` attribute of the `<address>` element in the WSDL.

When you update the JWS file, you add Java code to the methods so that the corresponding Web Service operations operate as required. Typically, the generated JWS file contains comments where you should add code, such as:

```java
//replace with your impl here```

In addition, you can add additional JWS annotations to the file, with the following restrictions:

- You can include the following annotations from the standard (JSR-181) `javax.jws` package in the JWS implementation file: `@WebService`, `@HandlerChain`, `@SOAPMessageHandler`, and `@SOAPMessageHandlers`. If you specify any other JWS annotation from the `javax.jws` package, the `jwsc` Ant task returns error when you try to compile the JWS file into a Web Service.

- You can specify only the `serviceName`, `endpointInterface`, and `targetNamespace` attributes of the `@WebService` annotation. Use the `serviceName` attribute to specify a different `<service>` WSDL element from the one that the `wsdlc` Ant task used, in the rare case that the WSDL file contains more than one `<service>` element. Use the `endpointInterface` attribute to specify the JWS SEI generated by the `wsdlc` Ant task. Use the `targetNamespace` attribute to specify the namespace of a WSDL service, which can be different from the one in JWS SEI.

- You can specify WebLogic-specific JWS annotations, as required.

After you have updated the JWS file, Oracle recommends that you move it to an official source location, rather than leaving it in the `wsdlc` output directory.

The following example shows the `wsdlc`-generated JWS implementation file from the WSDL shown in Section 2.3.1, "Sample WSDL File"; the text in **bold** indicates where
you would add Java code to implement the single operation (getTemp) of the Web Service:

```java
package examples.webservices.wsdlc;
import javax.jws.WebService;
import weblogic.jws.*;
/**
 * TemperaturePortTypeImpl class implements web service endpoint interface
 * TemperaturePortType */
@WebService(
    serviceName="TemperatureService",
    endpointInterface="examples.webservices.wsdlc.TemperaturePortType")
@WLHttpTransport(
    contextPath="temp",
    serviceUri="TemperatureService",
    portName="TemperaturePort")
public class TemperaturePortTypeImpl implements TemperaturePortType {
    public TemperaturePortTypeImpl() {
    }
    public float getTemp(java.lang.String zipcode)
    {
        //replace with your impl here
        return 0;
    }
}
```

### 3.9 Deploying and Undeploying WebLogic Web Services

Because Web Services are packaged as Enterprise Applications, deploying a Web Service simply means deploying the corresponding EAR file or exploded directory.

There are a variety of ways to deploy WebLogic applications, from using the WebLogic Server Administration Console to using the `weblogic.Deployer` Java utility. There are also various issues you must consider when deploying an application to a production environment as opposed to a development environment. For a complete discussion about deployment, see *Deploying Applications to Oracle WebLogic Server*.

This guide, because of its development nature, discusses just two ways of deploying Web Services:
- **Section 3.9.1, "Using the wldeploy Ant Task to Deploy Web Services"**
- **Section 3.9.2, "Using the Administration Console to Deploy Web Services"**

#### 3.9.1 Using the wldeploy Ant Task to Deploy Web Services

The easiest way to deploy a Web Service as part of the iterative development process is to add a target that executes the `wldeploy` WebLogic Ant task to the same `build.xml` file that contains the `jwsc` Ant task. You can add tasks to both deploy and undeploy the Web Service so that as you add more Java code and regenerate the service, you can redeploy and test it iteratively.

To use the `wldeploy` Ant task, add the following target to your `build.xml` file:

```xml
<target name="deploy">
    <wldeploy action="deploy"
        name="DeploymentName"
        source="Source" user="AdminUser"
        password="AdminPassword"
        adminurl="AdminServerURL"
```

where:

- **DeploymentName** refers to the deployment name of the Enterprise Application, or the name that appears in the WebLogic Server Administration Console under the list of deployments.
- **Source** refers to the name of the Enterprise Application EAR file or exploded directory that is being deployed. By default, the jwsc Ant task generates an exploded Enterprise Application directory.
- **AdminUser** refers to administrative username.
- **AdminPassword** refers to the administrative password.
- **AdminServerURL** refers to the URL of the Administration Server, typically t3://localhost:7001.
- **ServerName** refers to the name of the WebLogic Server instance to which you are deploying the Web Service.

For example, the following `wldeploy` task specifies that the Enterprise Application exploded directory, located in the `output/ComplexServiceEar` directory relative to the current directory, be deployed to the `myServer` WebLogic Server instance. Its deployed name is `ComplexServiceEar`.

```xml
<target name="deploy">
  <wldeploy action="deploy" name="ComplexServiceEar" source="output/ComplexServiceEar" user="weblogic" password="weblogic" verbose="true" adminurl="t3://localhost:7001" targets="myserver"/>
</target>
```

To actually deploy the Web Service, execute the `deploy` target at the command-line:

```bash
prompt> ant deploy
```

You can also add a target to easily undeploy the Web Service so that you can make changes to its source code, then redeploy it:

```xml
<target name="undeploy">
  <wldeploy action="undeploy" name="ComplexServiceEar" user="weblogic" password="weblogic" verbose="true" adminurl="t3://localhost:7001" targets="myserver"/>
</target>
```

When undeploying a Web Service, you do not specify the `source` attribute, but rather undeploy it by its name.

### 3.9.2 Using the Administration Console to Deploy Web Services

To use the WebLogic Server Administration Console to deploy the Web Service, first invoke it in your browser using the following URL:

```
http://host:port/console
```
where:

- **host** refers to the computer on which WebLogic Server is running.
- **port** refers to the port number on which WebLogic Server is listening (default value is 7001).

Then use the deployment assistants to help you deploy the Enterprise application. For more information on the WebLogic Server Administration Console, see the Oracle WebLogic Server Administration Console Online Help.

### 3.10 Browsing to the WSDL of the Web Service

You can display the WSDL of the Web Service in your browser to ensure that it has deployed correctly.

The following URL shows how to display the Web Service WSDL in your browser:

http://host:port/contextPath/serviceUri?WSDL

where:

- **host** refers to the computer on which WebLogic Server is running (for example, localhost).
- **port** refers to the port number on which WebLogic Server is listening (default value is 7001).
- **contextPath** refers to the context root of the Web Service. There are many places to set the context root (the contextPath attribute of the @WLHttpTransport annotation, the <WLHttpTransport>, <module>, or <jws> element of jwsc) and certain methods take precedence over others. See Chapter 3.6.2, "Defining the Context Path of a WebLogic Web Service."
- **serviceUri** refers to the value of the serviceUri attribute of the @WLHttpTransport JWS annotation of the JWS file that implements your Web Service or <WLHttpTransport> child element of the jwsc Ant task; the second takes precedence over the first. If you do not specify any serviceUri attribute in either the JWS file or the jwsc Ant task, then the serviceUri of the Web Service is the default value: the name of the JWS file without its *.java extension.

For example, assume you specified the following @WLHttpTransport annotation in the JWS file that implements your Web Service

```java
@WLHttpTransport(contextPath="complex",
                 serviceUri="ComplexService",
                 portName="ComplexServicePort")
/**
 * This JWS file forms the basis of a WebLogic Web Service.
 * *
 */
public class ComplexServiceImpl {
...
```

Further assume that you do not override the contextPath or serviceURI values by setting equivalent attributes for the <WLHttpTransport> element of the jwsc Ant task. Then the URL to view the WSDL of the Web Service, assuming the service is running on a host called ariel at the default port number (7001), is:

http://ariel:7001/complex/ComplexService?WSDL
3.11 Configuring the Server Address Specified in the Dynamic WSDL

The WSDL of a deployed Web Service (also called dynamic WSDL) includes an <address> element that assigns an address (URI) to a particular Web Service port. For example, assume that the following WSDL snippet partially describes a deployed WebLogic Web Service called ComplexService:

```xml
<definitions name="ComplexServiceDefinitions"
    targetNamespace="http://example.org">

    ...

    <service name="ComplexService">
        <port binding="s0:ComplexServiceSoapBinding" name="ComplexServicePort">
            <s1:address location="http://myhost:7101/complex/ComplexService"/>
        </port>
    </service>

</definitions>
```

The preceding example shows that the ComplexService Web Service includes a port called ComplexServicePort, and this port has an address of http://myhost:7101/complex/ComplexService.

WebLogic Server determines the complex/ComplexService section of this address by examining the contextPath and serviceURI attributes of the @WLXXXTransport annotations or jwsc elements, as described in Section 3.10, "Browsing to the WSDL of the Web Service." However, the method WebLogic Server uses to determine the protocol and host section of the address (http://myhost:7101, in the example) is more complicated, as described below. For clarity, this section uses the term server address to refer to the protocol and host section of the address.

The server address that WebLogic Server publishes in a dynamic WSDL of a deployed Web Service depends on whether the Web Service can be invoked using HTTP/S or JMS, whether you have configured a proxy server, whether the Web Service is deployed to a cluster, or whether the Web Service is actually a callback service.

The following sections reflect these different configuration options, and provide links to procedural information about changing the configuration to suit your needs.

- Section 3.11.1, "Web Service is not a callback service and can be invoked using HTTP/S"
- Section 3.11.2, "Web Service is not a callback service and can be invoked using JMS Transport"
- Section 3.11.3, "Web Service is a callback service"
- Section 3.11.4, "Web Service is invoked using a proxy server"

It is assumed in the sections that you use the WebLogic Server Administration Console to configure cluster and standalone servers.

3.11.1 Web Service is not a callback service and can be invoked using HTTP/S

1. If the Web Service is deployed to a cluster, and the cluster Frontend Host, Frontend HTTP Port, and Frontend HTTPS Port are set, then WebLogic Server uses these values in the server address of the dynamic WSDL.

See "Configure HTTP Settings for a Cluster" in the Oracle WebLogic Server Administration Console Online Help.
2. If the preceding cluster values are not set, but the `Frontend Host`, `Frontend HTTP Port`, and `Frontend HTTPS Port` values are set for the individual server to which the Web Service is deployed, then WebLogic Server uses these values in the server address.

   See “Configure HTTP Protocol” in the *Oracle WebLogic Server Administration Console Online Help*.

3. If these values are not set for the cluster or individual server, then WebLogic Server uses the server address of the WSDL request in the dynamic WSDL.

### 3.11.2 Web Service is not a callback service and can be invoked using JMS Transport

1. If the Web Service is deployed to a cluster and the `Cluster Address` is set, then WebLogic Server uses this value in the server address of the dynamic WSDL.

   See “Configure Clusters” in the *Oracle WebLogic Server Administration Console Online Help*.

2. If the cluster address is not set, or the Web Service is deployed to a standalone server, and the `Listen Address` of the server to which the Web Service is deployed is set, then WebLogic Server uses this value in the server address.

   See “Configure Listen Addresses” in the *Oracle WebLogic Server Administration Console Online Help*.

### 3.11.3 Web Service is a callback service

1. If the callback service is deployed to a cluster, and the cluster `Frontend Host`, `Frontend HTTP Port`, and `Frontend HTTPS Port` are set, then WebLogic Server uses these values in the server address of the dynamic WSDL.

   See “Configure HTTP Settings for a Cluster” in the *Oracle WebLogic Server Administration Console Online Help*.

2. If the callback service is deployed to either a cluster or a standalone server, and the preceding cluster values are not set, but the `Frontend Host`, `Frontend HTTP Port`, and `Frontend HTTPS Port` values are set for the individual server to which the callback service is deployed, then WebLogic Server uses these values in the server address.

   See “Configure HTTP Protocol” in the *Oracle WebLogic Server Administration Console Online Help*.

3. If the callback service is deployed to a cluster, but none of the preceding values are set, but the `Cluster Address` is set, then WebLogic Server uses this value in the server address.

   See “Configure Clusters” in the *Oracle WebLogic Server Administration Console Online Help*.

4. If none of the preceding values are set, but the `Listen Address` of the server to which the callback service is deployed is set, then WebLogic Server uses this value in the server address.

   See “Configure Listen Addresses” in the *Oracle WebLogic Server Administration Console Online Help*. 

3.11.4 Web Service is invoked using a proxy server

Although not required, Oracle recommends that you explicitly set the Frontend Host, FrontEnd HTTP Port, and Frontend HTTPS Port of either the cluster or individual server to which the Web Service is deployed to point to the proxy server.

See “Configure HTTP Settings for a Cluster” or “Configure HTTP Protocol” in the Oracle WebLogic Server Administration Console Online Help.

3.12 Testing the Web Service

After you have deployed a WebLogic Web Service, you can use the Web Services Test Client, included in the WebLogic Server Administration Console, to test your service without writing code. You can quickly and easily test any Web Service, including those with complex types and those using advanced features of WebLogic Server such as conversations. The test client automatically maintains a full log of requests allowing you to return to the previous call to view the results.

To test a deployed Web Service using the WebLogic Server Administration Console, follow these steps:

1. Invoke the WebLogic Server Administration Console in your browser using the following URL:
   
   http://host:port/console

   where:
   
   - host refers to the computer on which WebLogic Server is running.
   - port refers to the port number on which WebLogic Server is listening (default value is 7001).

2. Follow the procedure described in "Test a Web Service" in the Oracle WebLogic Server Administration Console Online Help.

3.13 Integrating Web Services Into the WebLogic Split Development Directory Environment

This section describes how to integrate Web Services development into the WebLogic split development directory environment. It is assumed that you understand this WebLogic feature and have set up this type of environment for developing standard Java Platform, Enterprise Edition (Java EE) Version 5 applications and modules, such as EJBs and Web applications, and you want to update the single build.xml file to include Web Services development.

For detailed information about the WebLogic split development directory environment, see "Creating a Split Development Directory for an Application" in Developing Applications for Oracle WebLogic Server and the splitdir/helloWorldEar example optionally installed with WebLogic Server, located in the EXAMPLES_HOME/wl_server/examples/src/examples directory, where EXAMPLES_HOME represents the directory in which the WebLogic Server code examples are configured. The default path is ORACLE_HOME\user_projects\applications. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in Understanding Oracle WebLogic Server.

1. In the main project directory, create a directory that will contain the JWS file that implements your Web Service.
For example, if your main project directory is called /src/helloWorldEar, then create a directory called /src/helloWorldEar/helloWebService:

prompt> mkdir /src/helloWorldEar/helloWebService

2. Create a directory hierarchy under the helloWebService directory that corresponds to the package name of your JWS file.

For example, if your JWS file is in the package examples.splitdir.hello package, then create a directory hierarchy examples/splitdir/hello:

prompt> cd /src/helloWorldEar/helloWebService
prompt> mkdir examples/splitdir/hello

3. Put your JWS file in the just-created Web Service subdirectory of your main project directory (/src/helloWorldEar/helloWebService/examples/splitdir/hello in this example.)

4. In the build.xml file that builds the Enterprise application, create a new target to build the Web Service, adding a call to the jwsc WebLogic Web Service Ant task, as described in Section 3.6, "Running the jwsc WebLogic Web Services Ant Task."

The jwsc srcdir attribute should point to the top-level directory that contains the JWS file (helloWebService in this example). The jwsc destdir attribute should point to the same destination directory you specify for wlcompile, as shown in the following example:

```xml
<target name="build.helloWebService">
  <jwsc
    srcdir="helloWebService"
    destdir="destination_dir"
    keepGenerated="yes"
    >
    <jws file="examples/splitdir/hello/HelloWorldImpl.java"
      type="JAXRPC" />
  </jwsc>
</target>
```

In the example, destination_dir refers to the destination directory that the other split development directory environment Ant tasks, such as wlappc and wlcompile, also use.

5. Update the main build target of the build.xml file to call the Web Service-related targets:

```xml
<!-- Builds the entire helloWorldEar application -->
<target name="build"
  description="Compiles helloWorldEar application and runs appc"
  depends="build-helloWebService,compile,appc"
  />
7. **Update the application.xml file in the META-INF project source directory, adding a <web> module and specifying the name of the WAR file generated by the jwsc Ant task.**

For example, add the following to the application.xml file for the helloWorld Web Service:

```xml
<application>
    ...
    <module>
        <web>
            <web-uri>examples/splitdir/hello/HelloWorldImpl.war</web-uri>
            <context-root>/hello</context-root>
        </web>
    </module>
    ...
</application>
```

---

**Note:** The jwsc Ant task always generates a Web Application WAR file from the JWS file that implements your Web Service, unless your JWS file explicitly implements `javax.ejb.SessionBean`. In that case you must add an `<ejb>` module element to the `application.xml` file instead.

---

Your split development directory environment is now updated to include Web Service development. When you rebuild and deploy the entire Enterprise Application, the Web Service will also be deployed as part of the EAR. You invoke the Web Service in the standard way described in Section 3.10, "Browsing to the WSDL of the Web Service."
This chapter describes how to program the JWS file that implements the WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following sections:

- Overview of JWS Files and JWS Annotations
- Java Requirements for a JWS File
- Programming the JWS File: Typical Steps
- Accessing Run-Time Information About a Web Service
- Should You Implement a Stateless Session EJB?
- Programming the User-Defined Java Data Type
- Throwing Exceptions
- Invoking Another Web Service from the JWS File
- Programming Additional Miscellaneous Features Using JWS Annotations and APIs
- JWS Programming Best Practices

4.1 Overview of JWS Files and JWS Annotations

There are two ways to program a WebLogic web service from scratch:

1. Annotate a standard EJB or Java class with web service Java annotations, as defined by JSR-181, the JAX-WS specification, and by the WebLogic web services programming model.

2. Combine a standard EJB or Java class with the various XML descriptor files and artifacts specified by JSR-109 (such as, deployment descriptors, WSDL files, data mapping descriptors, data binding artifacts for user-defined data types, and so on).

Oracle strongly recommends using option 1 above. Instead of authoring XML metadata descriptors yourself, the WebLogic Ant tasks and run time will generate the required descriptors and artifacts based on the annotations you include in your JWS. Not only is this process much easier, but it keeps the information about your web service in a central location, the JWS file, rather than scattering it across many Java and XML files.

The Java Web Service (JWS) annotated file is the core of your web service. It contains the Java code that determines how your web service behaves. A JWS file is an ordinary
Java Requirements for a JWS File

Java class file that uses Java metadata annotations to specify the shape and characteristics of the web service. The JWS annotations you can use in a JWS file include the standard ones defined by the Web Services Metadata for the Java Platform specification (JSR-181), described at http://www.jcp.org/en/jsr/detail?id=181, plus a set of additional annotations based on the type of web service you are building—JAX-WS or JAX-RPC. For a complete list of JWS annotations that are supported for JAX-WS and JAX-RPC web services, see "Web Service Annotation Support" in WebLogic Web Services Reference for Oracle WebLogic Server.

When programming the JWS file, you include annotations to program basic web service features. The annotations are used at different levels, or targets, in your JWS file. Some are used at the class-level to indicate that the annotation applies to the entire JWS file. Others are used at the method-level and yet others at the parameter level.

4.2 Java Requirements for a JWS File

When you program your JWS file, you must follow a set of requirements, as specified by the Web Services Metadata for the Java Platform specification (JSR-181) at http://www.jcp.org/en/jsr/detail?id=181. In particular, the Java class that implements the web service:

- Must be an outer public class, must not be declared final, and must not be abstract.
- Must have a default public constructor.
- Must not define a finalize() method.
- Must include, at a minimum, a @WebService JWS annotation at the class level to indicate that the JWS file implements a web service.
- May reference a service endpoint interface by using the @WebService.endpointInterface annotation. In this case, it is assumed that the service endpoint interface exists and you cannot specify any other JWS annotations in the JWS file other than @WebService.endpointInterface, @WebService.serviceName, and @WebService.targetNamespace.
- If JWS file does not implement a service endpoint interface, all public methods other than those inherited from java.lang.Object will be exposed as web service operations. This behavior can be overridden by using the @WebMethod annotation to specify explicitly the public methods that are to be exposed. If a @WebMethod annotation is present, only the methods to which it is applied are exposed.

4.3 Programming the JWS File: Typical Steps

The following procedure describes the typical steps for programming a JWS file that implements a web service.

Note: It is assumed that you have created a JWS file and now want to add JWS annotations to it.

For more information about each of the JWS annotations, see "JWS Annotation Reference" in WebLogic Web Services Reference for Oracle WebLogic Server. See Part III, "Developing Advanced Features of JAX-RPC Web Services" for information on using other JWS annotations to program more advanced features, such as web service reliable messaging, conversations, SOAP message handlers, and so on.
### Table 4–1  Steps to Program the JWS File

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Import the standard JWS annotations that will be used in your JWS file.</td>
<td>The standard JWS annotations are in either the javax.jws or javax.jws.soap package. For example: import javax.jws.WebMethod; import javax.jws.WebService; import javax.jws.soap.SOAPBinding;</td>
</tr>
<tr>
<td>2</td>
<td>Import the WebLogic-specific annotations used in your JWS file.</td>
<td>The WebLogic-specific annotations are in the weblogic.jws package. For example: import weblogic.jws.WLHttpTransport;</td>
</tr>
<tr>
<td>3</td>
<td>Add the standard required @WebService JWS annotation at the class level to specify that the Java class exposes a web service.</td>
<td>See Section 4.3.2, &quot;Specifying that the JWS File Implements a Web Service (@WebService Annotation).&quot;</td>
</tr>
<tr>
<td>4</td>
<td>Add the standard @SOAPBinding JWS annotation at the class level to specify the mapping between the web service and the SOAP message protocol. (Optional)</td>
<td>In particular, use this annotation to specify whether the web service is document-literal, RPC-encoded, and so on. See Section 4.3.3, &quot;Specifying the Mapping of the Web Service to the SOAP Message Protocol (@SOAPBinding Annotation).&quot; Although this JWS annotation is not required, Oracle recommends you explicitly specify it in your JWS file to clarify the type of SOAP bindings a client application uses to invoke the web service.</td>
</tr>
<tr>
<td>5</td>
<td>Add the WebLogic-specific @WLHttpTransport JWS annotation at the class level to specify the context path and service URI used in the URL that invokes the web service. (Optional)</td>
<td>See Section 4.3.4, &quot;Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation).&quot; Although this JWS annotation is not required, Oracle recommends you explicitly specify it in your JWS file so that it is clear what URL a client application uses to invoke the web service.</td>
</tr>
<tr>
<td>6</td>
<td>Add the standard @WebMethod annotation for each method in the JWS file that you want to expose as a public operation. (Optional)</td>
<td>Optionally specify that the operation takes only input parameters but does not return any value by using the standard @OneWay annotation. See Section 4.3.5, &quot;Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and @OneWay Annotations).&quot;</td>
</tr>
<tr>
<td>7</td>
<td>Add @WebParam annotation to customize the name of the input parameters of the exposed operations. (Optional)</td>
<td>See Section 4.3.6, &quot;Customizing the Mapping Between Operation Parameters and WSDL Elements (@WebParam Annotation).&quot;</td>
</tr>
<tr>
<td>8</td>
<td>Add @WebResult annotations to customize the name and behavior of the return value of the exposed operations. (Optional)</td>
<td>See Section 4.3.7, &quot;Customizing the Mapping Between the Operation Return Value and a WSDL Element (@WebResult Annotation).&quot;</td>
</tr>
<tr>
<td>9</td>
<td>Add your business code.</td>
<td>Add your business code to the methods to make the WebService behave as required.</td>
</tr>
</tbody>
</table>

### 4.3.1 Example of a JWS File

The following sample JWS file shows how to implement a simple web service.

```java
package examples.webservices.simple;
// Import the standard JWS annotation interfaces
```
import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.soap.SOAPBinding;
// Import the WebLogic-specific JWS annotation interfaces
import weblogic.jws.WLHttpTransport;
// Standard JWS annotation that specifies that the portType name of the Web
// Service is "SimplePortType", the service name is "SimpleService", and the
// targetNamespace used in the generated WSDL is "http://example.org"
@WebService(name="SimplePortType", serviceName="SimpleService",
targetNamespace="http://example.org")
// Standard JWS annotation that specifies the mapping of the service onto the
// SOAP message protocol. In particular, it specifies that the SOAP messages
// are document-literal-wrapped.
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
    use=SOAPBinding.Use.LITERAL,
    parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
// WebLogic-specific JWS annotation that specifies the context path and
// service URI used to build the URI of the Web Service is
// "simple/SimpleService"
@WLHttpTransport(contextPath="simple", serviceUri="SimpleService",
    portName="SimpleServicePort")
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHello
 *
 */
public class SimpleImpl {
    // Standard JWS annotation that specifies that the method should be exposed
    // as a public operation. Because the annotation does not include the
    // member-value 'operationName', the public name of the operation is the
    // same as the method name: sayHello.
    @WebMethod()
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: '" + message + "'";
    }
}

4.3.2 Specifying that the JWS File Implements a Web Service (@WebService Annotation)

Use the standard @WebService annotation to specify, at the class level, that the JWS file
implements a web service, as shown in the following code excerpt:

@WebService(name="SimplePortType", serviceName="SimpleService",
targetNamespace="http://example.org")

In the example, the name of the web service is SimplePortType, which will later map
to the wsdl:portType element in the WSDL file generated by the jwsc Ant task. The
service name is SimpleService, which will map to the wsdl:service element in the
generated WSDL file. The target namespace used in the generated WSDL is
http://example.org.

You can also specify the following additional attributes of the @WebService annotation:

- endpointInterface—Fully qualified name of an existing service endpoint
  interface file. This annotation allows the separation of interface definition from the
  implementation. If you specify this attribute, the jwsc Ant task does not generate
the interface for you, but assumes you have created it and it is in your CLASSPATH.

- **portname**—Name that is used in the `wsdl:port`.

None of the attributes of the `@WebService` annotation is required. See the *Web Services Metadata for the Java Platform* (JSR 181) at [http://www.jcp.org/en/jsr/detail?id=181](http://www.jcp.org/en/jsr/detail?id=181) for the default values of each attribute.

### 4.3.3 Specifying the Mapping of the Web Service to the SOAP Message Protocol (@SOAPBinding Annotation)

It is assumed that you want your web service to be available over the SOAP message protocol; for this reason, your JWS file should include the standard `@SOAPBinding` annotation, at the class level, to specify the SOAP bindings of the web service (such as, RPC-encoded or document-literal-wrapped), as shown in the following code excerpt:

```java
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
             use=SOAPBinding.Use.LITERAL,
             parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
```

In the example, the web service uses document-wrapped-style encodings and literal message formats, which are also the default formats if you do not specify the `@SOAPBinding` annotation.

You can also use the WebLogic-specific `@weblogic.jws.soap.SOAPBinding` annotation to specify the SOAP binding at the method level; the attributes are the same as the standard `@javax.jws.soap.SOAPBinding` annotation.

You use the `parameterStyle` attribute (in conjunction with the `style=SOAPBinding.Style.DOCUMENT` attribute) to specify whether the web service operation parameters represent the entire SOAP message body, or whether the parameters are elements wrapped inside a top-level element with the same name as the operation.

### Table 4-2 Attributes of the @SOAPBinding Annotation

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Possible Values</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>style</strong></td>
<td><code>SOAPBinding.Style.RPC</code></td>
<td><code>SOAPBinding.Style.DOCUMENT</code></td>
</tr>
<tr>
<td></td>
<td><code>SOAPBinding.Style.DOCUMENT</code></td>
<td></td>
</tr>
<tr>
<td><strong>use</strong></td>
<td><code>SOAPBinding.Use.LITERAL</code></td>
<td><code>SOAPBinding.Use.LITERAL</code></td>
</tr>
<tr>
<td></td>
<td><code>SOAPBinding.Use.ENCODED</code></td>
<td></td>
</tr>
<tr>
<td><strong>parameterStyle</strong></td>
<td><code>SOAPBinding.ParameterStyle.BARE</code></td>
<td><code>SOAPBinding.ParameterStyle.WRAPPED</code></td>
</tr>
<tr>
<td></td>
<td><code>SOAPBinding.ParameterStyle.WRAPPED</code></td>
<td></td>
</tr>
</tbody>
</table>

### 4.3.4 Specifying the Context Path and Service URI of the Web Service (@WLHttpTransport Annotation)

Use the WebLogic-specific `@WLHttpTransport` annotation to specify the context path and service URI sections of the URL used to invoke the web service over the HTTP transport, as well as the name of the port in the generated WSDL, as shown in the following code excerpt:

```java
@WLHttpTransport(contextPath="simple", serviceUri="SimpleService",
                  portName="SimpleServicePort")
```

In the example, the name of the port in the WSDL (in particular, the `name` attribute of the `<port>` element) file generated by the `jwsc` Ant task is `SimpleServicePort`. The
URL used to invoke the web service over HTTP includes a context path of `simple` and a service URI of `SimpleService`, as shown in the following example:

```
http://host:port/simple/SimpleService
```

For reference documentation on this and other WebLogic-specific annotations, see "JWS Annotation Reference" in the WebLogic Web Services Reference.

### 4.3.5 Specifying That a JWS Method Be Exposed as a Public Operation (@WebMethod and @OneWay Annotations)

Use the standard `@WebMethod` annotation to specify that a method of the JWS file should be exposed as a public operation of the web service, as shown in the following code excerpt:

```java
public class SimpleImpl {
    @WebMethod(operationName="sayHelloOperation")
    public String sayHello(String message) {
        System.out.println("sayHello:");
        return "Here is the message: " + message + ";";
    }
    ...
```

In the example, the `sayHello()` method of the `SimpleImpl` JWS file is exposed as a public operation of the web service. The `operationName` attribute specifies, however, that the public name of the operation in the WSDL file is `sayHelloOperation`. If you do not specify the `operationName` attribute, the public name of the operation is the name of the method itself.

You can also use the `action` attribute to specify the action of the operation. When using SOAP as a binding, the value of the `action` attribute determines the value of the `SOAPAction` header in the SOAP messages.

You can specify that an operation not return a value to the calling application by using the standard `@Oneway` annotation, as shown in the following example:

```java
public class OneWayImpl {
    @WebMethod()
    @Oneway()
    public void ping() {
        System.out.println("ping operation");
    }
    ...
```

If you specify that an operation is one-way, the implementing method is required to return `void`, cannot use a Holder class as a parameter, and cannot throw any checked exceptions.

None of the attributes of the `@WebMethod` annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at [http://www.jcp.org/en/jsr/detail?id=181](http://www.jcp.org/en/jsr/detail?id=181) for the default values of each attribute, as well as additional information about the `@WebMethod` and `@Oneway` annotations.

If none of the public methods in your JWS file are annotated with the `@WebMethod` annotation, then by default all public methods are exposed as web service operations.
4.3.6 Customizing the Mapping Between Operation Parameters and WSDL Elements (@WebParam Annotation)

Use the standard @WebParam annotation to customize the mapping between operation input parameters of the web service and elements of the generated WSDL file, as well as specify the behavior of the parameter, as shown in the following code excerpt:

```java
public class SimpleImpl {
    @WebMethod()
    @WebResult(name="IntegerOutput",
                targetNamespace="http://example.org/docLiteralBare")
    public int echoInt(
            @WebParam(name="IntegerInput",
                       targetNamespace="http://example.org/docLiteralBare")
            int input)
    {
        System.out.println("echoInt " + input + " to you too!");
        return input;
    }
    ...
}
```

In the example, the name of the parameter of the echoInt operation in the generated WSDL is IntegerInput; if the @WebParam annotation were not present in the JWS file, the name of the parameter in the generated WSDL file would be the same as the name of the method’s parameter: input. The targetNamespace attribute specifies that the XML namespace for the parameter is http://example.org/docLiteralBare; this attribute is relevant only when using document-style SOAP bindings where the parameter maps to an XML element.

You can also specify the following additional attributes of the @WebParam annotation:

- **mode**—The direction in which the parameter is flowing (@WebParam.Mode.IN, WebParam.Mode.OUT, or WebParam.Mode.INOUT). The OUT and INOUT modes may be specified only for parameter types that conform to the JAX-RPC definition of Holder types. OUT and INOUT modes are only supported for RPC-style operations or for parameters that map to headers.

- **header**—Boolean attribute that, when set to true, specifies that the value of the parameter should be retrieved from the SOAP header, rather than the default body.

None of the attributes of the @WebParam annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at http://www.jcp.org/en/jsr/detail?id=181 for the default value of each attribute.

4.3.7 Customizing the Mapping Between the Operation Return Value and a WSDL Element (@WebResult Annotation)

Use the standard @WebResult annotation to customize the mapping between the web service operation return value and the corresponding element of the generated WSDL file, as shown in the following code excerpt:

```java
public class Simple {
    @WebMethod()
    @WebResult(name="IntegerOutput",
                targetNamespace="http://example.org/docLiteralBare")
    public int echoInt(
            @WebParam(name="IntegerInput",
                       targetNamespace="http://example.org/docLiteralBare")
            int input)
    }
```
In the example, the name of the return value of the echoInt operation in the generated WSDL is IntegerOutput; if the @WebResult annotation were not present in the JWS file, the name of the return value in the generated WSDL file would be the hard-coded name return. The targetNamespace attribute specifies that the XML namespace for the return value is http://example.org/docLiteralBare; this attribute is relevant only when using document-style SOAP bindings where the return value maps to an XML element.

None of the attributes of the @WebResult annotation is required. See the Web Services Metadata for the Java Platform (JSR 181) at http://www.jcp.org/en/jsr/detail?id=181 for the default value of each attribute.

### 4.4 Accessing Run-Time Information About a Web Service

The following sections describe how to access run-time information about a web service:

- **Section 4.4.1, "Using JwsContext to Access Run-Time Information"**—Use the web service context to access and change run-time information about the service in your JWS file.
- **Section 4.4.2, "Using the Stub Interface to Access Run-Time Information"**—Get and set properties on the Stub interface in the client file.

#### 4.4.1 Using JwsContext to Access Run-Time Information

When a client application invokes a WebLogic web service that was implemented with a JWS file, WebLogic Server automatically creates a context that the web service can use to access, and sometimes change, run-time information about the service. Much of this information is related to conversations, such as whether the current conversation is finished, the current values of the conversational properties, changing conversational properties at run time, and so on. (See Chapter 9, "Creating Conversational Web Services" for information about conversations and how to implement them.) Some of the information accessible via the context is more generic, such as the protocol that was used to invoke the web service (HTTP/S or JMS), the SOAP headers that were in the SOAP message request, and so on.

You can use annotations and WebLogic web service APIs in your JWS file to access run-time context information, as described in the following sections.

#### 4.4.1.1 Guidelines for Accessing the Web Service Context

The following example shows a simple JWS file that uses the context to determine the protocol that was used to invoke the web service. The code in **bold** is discussed in the programming guidelines described following the example.

```java
package examples.webservices.jws_context;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.wsee.jws.JwsContext;
import weblogic.wsee.jws.Protocol;
```
/**
* Simple web service to show how to use the @Context annotation.
*/
public class JwsContextImpl {
    @Context
    private JwsContext ctx;
    @WebMethod()
    public String getProtocol() {
        Protocol protocol = ctx.getProtocol();
        System.out.println("protocol: " + protocol);
        return "This is the protocol: " + protocol;
    }
}

Use the following guidelines in your JWS file to access the run-time context of the web service, as shown in the code in bold in the preceding example:

- Import the @weblogic.jws.Context JWS annotation:
  
  import weblogic.jws.Context;

- Import the weblogic.wsee.jws.JwsContext API, as well as any other related APIs that you might use (the example also uses the weblogic.wsee.jws.Protocol API):
  
  import weblogic.wsee.jws.JwsContext;
  import weblogic.wsee.jws.Protocol;

  See the weblogic.wsee.* packages in the Java API Reference for Oracle WebLogic Server for more documentation about the context-related APIs.

- Annotate a private variable, of data type weblogic.wsee.jws.JwsContext, with the field-level @Context JWS annotation:
  
  @Context
  private JwsContext ctx;

  WebLogic Server automatically assigns the annotated variable (in this case, ctx) with a run-time implementation of JwsContext the first time the web service is invoked, which is how you can later use the variable without explicitly initializing it in your code.

  Use the methods of the JwsContext class to access run-time information about the web service. The following example shows how to get the protocol that was used to invoke the web service.

  Protocol protocol = ctx.getProtocol();

  See Section 4.4.1.2, "Methods of the JwsContext" for the full list of available methods.

4.4.1.2 Methods of the JwsContext

The following table summarizes the methods of the JwsContext that you can use in your JWS file to access run-time information about the web service. See weblogic.wsee.* packages in the Java API Reference for Oracle WebLogic Server for detailed reference information about JwsContext, and other context-related APIs, as Protocol and ServiceHandle.
### Table 4–3  Methods of JwsContext

<table>
<thead>
<tr>
<th>Method</th>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isFinished()</td>
<td>boolean</td>
<td>Returns a boolean value specifying whether the current conversation is finished, or if it is still continuing. Use this method only in conversational web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>finishConversation()</td>
<td>void</td>
<td>Finishes the current conversation. This method is equivalent to a client application invoking a method that has been annotated with the @Conversation (Conversation.Phase.FINISH) JWS annotation. Use this method only in conversational web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxAge(java.util.Date)</td>
<td>void</td>
<td>Sets a new maximum age for the conversation to an absolute Date. If the date parameter is in the past, WebLogic Server immediately finishes the conversation. This method is equivalent to the maxAge attribute of the @Conversational annotation, which specifies the default maximum age of a conversation. Use this method to override this default value at run time. Use this method only in conversational web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>setMaxAge(String)</td>
<td>void</td>
<td>Sets a new maximum age for the conversation by specifying a String duration, such as 1 day. Valid values for the String parameter are a number and one of the following terms: - seconds - minutes - hours - days - years For example, to specify a maximum age of ten minutes, use the following syntax: ctx.setMaxAge(&quot;10 minutes&quot;) This method is equivalent to the maxAge attribute of the @Conversational annotation, which specifies the default maximum age of a conversation. Use this method to override this default value at run time. Use this method only in conversational web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
<tr>
<td>getMaxAge()</td>
<td>long</td>
<td>Returns the maximum allowed age, in seconds, of a conversation. Use this method only in conversational web services, or those that have been annotated with the @Conversation or @Conversational annotation.</td>
</tr>
</tbody>
</table>

</tbody>
</table>
Accessing Run-Time Information About a Web Service

Table 4–3 (Cont.) Methods of JwsContext
Method

Returns

Description

getCurrentIdleTime
()

long

Gets the number of seconds since the last client
request, or since the conversation's maximum idle
time was reset.
Use this method only in conversational web services,
or those that have been annotated with the
@Conversation or @Conversational annotation.

getCallerPrincipal
()

java.security Returns the security principal associated with the
operation that was just invoked, assuming that basic
.Principal
authentication was performed.

isCallerInRole(Str
ing)

boolean

getService()

weblogic.wsee Returns an instance of ServiceHandle, a WebLogic
.jws.ServiceH web service API, which you can query to gather
additional information about the web service, such as
andle
the conversation ID (if the web service is
conversational), the URL of the web service, and so
on.

getLogger(String)

weblogic.wsee Gets an instance of the Logger class, which you can
.jws.util.Log use to send messages from the web service to a log
file.
ger

getInputHeaders()

org.w3c.dom.E Returns an array of the SOAP headers associated with
the SOAP request message of the current operation
lement[]
invoke.

setUnderstoodInput
Headers(boolean)

void

Indicates whether input headers should be
understood.

getUnderstoodInput
Headers()

boolean

Returns the value that was most recently set by a call
to setUnderstoodInputHeader.

setOutputHeaders(E
lement[])

void

Specifies an array of SOAP headers that should be
associated with the outgoing SOAP response message
sent back to the client application that initially
invoked the current operation.

getProtocol()

weblogic.wsee Returns the protocol (such as HTTP/S or JMS) used to
.jws.Protocol invoke the current operation.

Returns true if the authenticated principal is within
the specified security role.

4.4.2 Using the Stub Interface to Access Run-Time Information
Thejavax.xml.rpc.Stub interface enables you to dynamically configure the Stub
instance in your web service client file. For more information, see
http://download.oracle.com/javaee/6/api/javax/xml/rpc/Stub.html. For
example, you can set the target service endpoint dynamically for the port Stub
instance, as follows:
ComplexService service = new ComplexService_Impl (args[0] + "?WSDL" );
ComplexPortType port = service.getComplexServicePort();
((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY,
"http://localhost:8010/MyContext/MyService");

For more information about developing web service clients, see Chapter 6,
"Developing JAX-RPC Web Service Clients."
The following table summarizes the methods of the Stub interface that you can use in
your JWS file to access run-time information about the web service.

4-12 Developing JAX-RPC Web Services for Oracle WebLogic Server 12.1.3

4.5 Should You Implement a Stateless Session EJB?

The `jwsc` Ant task always chooses a plain Java object as the underlying implementation of a web service when processing your JWS file.

Sometimes, however, you might want the underlying implementation of your web service to be a stateless session EJB so as to take advantage of all that EJBs have to offer, such as instance pooling, transactions, security, container-managed persistence, container-managed relationships, and data caching. If you decide you want an EJB implementation for your web service, then follow the programming guidelines in the following section.

**Note:** JAX-RPC supports EJB 2.x only; it does not support EJB 3.0.

4.5.1 Programming Guidelines When Implementing an EJB in Your JWS File

The general guideline is to always use EJBGen annotations in your JWS file to automatically generate, rather than manually create, the EJB Remote and Home interface classes and deployment descriptor files needed when implementing an EJB. EJBGen annotations work in the same way as JWS annotations: they follow the JDK 5.0 metadata syntax and greatly simplify your programming tasks.

For more information on EJBGen, see "EJBGen Reference" in Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server.

Follow these guidelines when explicitly implementing a stateless session EJB in your JWS file. See Section 4.5.2, "Example of a JWS File That Implements an EJB" for an example; the relevant sections are shown in **bold**:

- Import the standard Java Platform, Enterprise Edition (Java EE) Version 5 EJB classes:
import javax.ejb.SessionBean;
import javax.ejb.SessionContext;

- Import the EJBGen annotations, all of which are in the weblogic.ejbgen package. At a minimum you need to import the @Session annotation; if you want to use additional EJBGen annotations in your JWS file to specify the shape and behavior of the EJB, see the "EJBGen Reference" in Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server for the name of the annotation you should import.

  import weblogic.ejbgen.Session;

- At a minimum, use the @Session annotation at the class level to specify the name of the EJB:

  @Session(ejbName="TransactionEJB")

  @Session is the only required EJBGen annotation when used in a JWS file. You can, if you want, use other EJBGen annotations to specify additional features of the EJB.

- Ensure that the JWS class implements SessionBean:

  public class TransactionImpl implements SessionBean {...

- You must also include the standard EJB methods ejbCreate(), ejbActivate() and so on, although you typically do not need to add code to these methods unless you want to change the default behavior of the EJB:

  public void ejbCreate() {
      public void ejbActivate() {
      public void ejbRemove() {
      public void ejbPassivate() {
      public void setSessionContext(SessionContext sc) {

If you follow all these guidelines in your JWS file, the jwsc Ant task later compiles the web service into an EJB and packages it into an EJB JAR file inside of the Enterprise Application.

### 4.5.2 Example of a JWS File That Implements an EJB

The following example shows a simple JWS file that implement a stateless session EJB. The relevant code is shown in bold.

```
package examples.webservices.transactional;
import javax.ejb.SessionBean;
import javax.ejb.SessionContext;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Transactional;
import weblogic.ejbgen.Session;
@Session(ejbName="TransactionEJB")
@WebService(name="TransactionPortType", serviceName="TransactionService",
            targetNamespace="http://example.org")
@WLHttpTransport(contextPath="transactions", serviceUri="TransactionService",
        portName="TransactionPort")
/**
 * This JWS file forms the basis of simple EJB-implemented WebLogic
 * Web Service with a single operation: sayHello. The operation executes
 * as part of a transaction.
 */
```
4.6 Programming the User-Defined Java Data Type

The methods of the JWS file that are exposed as web service operations do not necessarily take built-in data types (such as Strings and integers) as parameters and return values, but rather, might use a Java data type that you create yourself. An example of a user-defined data type is `TradeResult`, which has two fields: a `String` stock symbol and an integer number of shares traded.

If your JWS file uses user-defined data types as parameters or return values of one or more of its methods, you must create the Java code of the data type yourself, and then import the class into your JWS file and use it appropriately. The jwsc Ant task will later take care of creating all the necessary data binding artifacts, such as the corresponding XML Schema representation of the Java user-defined data type, the JAX-RPC type mapping file, and so on.

Follow these basic requirements when writing the Java class for your user-defined data type:

- Define a default constructor, which is a constructor that takes no parameters.
- Define both `getXXX()` and `setXXX()` methods for each member variable that you want to publicly expose.
- Make the data type of each exposed member variable one of the built-in data types, or another user-defined data type that consists of built-in data types.

These requirements are specified by JAX-RPC; for more detailed information and the complete list of requirements, see the JAX-RPC specification at [http://java.net/projects/jax-rpc/](http://java.net/projects/jax-rpc/).

The jwsc Ant task can generate data binding artifacts for most common XML and Java data types. For the list of supported user-defined data types, see Section 5.3, "Supported User-Defined Data Types." See Section 5.2, "Supported Built-In Data Types" for the full list of supported built-in data types.

The following example shows a simple Java user-defined data type called `BasicStruct`:

```java
package examples.webservices.complex;

/**
 * Defines a simple JavaBean called BasicStruct that has integer, String,
 * and String[] properties
 */
public class BasicStruct {
```
4.7 Throwing Exceptions

When you write the error-handling Java code in methods of the JWS file, you can either throw your own user-defined exceptions or throw a `javax.xml.rpc.soap.SOAPFaultException` exception. If you throw a `SOAPFaultException`, WebLogic Server maps it to a SOAP fault and sends it to the client application that invokes the operation.
If your JWS file throws any type of Java exception other than SOAPFaultException, WebLogic Server tries to map it to a SOAP fault as best it can. However, if you want to control what the client application receives and send it the best possible exception information, you should explicitly throw a SOAPFaultException exception or one that extends the exception. See the JAX-RPC specification at http://java.net/projects/jax-rpc/ for detailed information about creating and throwing your own user-defined exceptions.

The following excerpt describes the SOAPFaultException class:

```java
public class SOAPFaultException extends java.lang.RuntimeException {
    public SOAPFaultException (QName faultcode, String faultstring, String faultactor, javax.xml.soap.Detail detail) {...}
    public QName getFaultCode() {...}
    public String getFaultString() {...}
    public String getFaultActor() {...}
    public javax.xml.soap.Detail getDetail() {...}
}
```

Use the SOAP with Attachments API for Java 1.1 (SAAJ) javax.xml.soap.SOAPFactory.createDetail() method to create the Detail object, which is a container for DetailEntry objects that provide detailed application-specific information about the error.

You can use your own implementation of the SOAPFactory, or use Oracle’s, which can be accessed in the JWS file by calling the static method weblogic.wsee.util.WLSOAPFactory.createSOAPFactory() which returns a javax.xml.soap.SOAPFactory object. Then at run time, use the -Djavax.xml.soap.SOAPFactory flag to specify Oracle’s SOAPFactory implementation as shown:

- Djavax.xml.soap.SOAPFactory=weblogic.xml.saaj.SOAPFactoryImpl

The following JWS file shows an example of creating and throwing a SOAPFaultException from within a method that implements an operation of your web service; the sections in bold highlight the exception code:

```java
package examples.webservices.soap_exceptions;
import javax.xml.namespace.QName;
import javax.xml.soap.Detail;
import javax.xml.soap.SOAPException;
import javax.xml.soap.SOAPFactory;
import javax.xml.rpc.soap.SOAPFaultException;
// Import the @WebService annotation
import javax.jws.WebService;
// Import WLHttpTransport
import weblogic.jws.WLHttpTransport;
@WebService(serviceName="SoapExceptionsService",
           name="SoapExceptionsPortType",
           targetNamespace="http://example.org")
@WLHttpTransport(contextPath="exceptions",
                 serviceUri="SoapExceptionsService",
                 portName="SoapExceptionsServicePort")
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHelloWorld
 */
public class SoapExceptionsImpl {
```
public SoapExceptionsImpl() {
}
public void tirarSOAPException() {
    Detail detail = null;
    try {
        SOAPFactory soapFactory = SOAPFactory.newInstance();
        detail = soapFactory.createDetail();
    } catch (SOAPException e) {
        // do something
    }
    QName faultCode = null;
    String faultString = "the fault string";
    String faultActor = "the fault actor";
    throw new SOAPFaultException(faultCode, faultString, faultActor, detail);
}

The preceding example uses the default implementation of SOAPFactory.

---

**Note:** If you create and throw your own exception (rather than use SOAPFaultException) and two or more of the properties of your exception class are of the same data type, then you must also create setter methods for these properties, even though the JAX-RPC specification does not require it. This is because when a WebLogic web service receives the exception in a SOAP message and converts the XML into the Java exception class, there is no way of knowing which XML element maps to which class property without the corresponding setter methods.

---

### 4.8 Invoking Another Web Service from the JWS File

From within your JWS file you can invoke another web service, either one deployed on WebLogic Server or one deployed on some other application server, such as .NET. The steps to do this are similar to those described in Section 2.4, "Invoking a Web Service from a Java SE Client," except that rather than running the clientgen Ant task to generate the client stubs, you include a `<clientgen>` child element of the jwsc Ant task that builds the invoking web service to generate the client stubs instead. You then use the standard JAX-RPC APIs in your JWS file.

See Section 6.3, "Invoking a Web Service from Another Web Service" for detailed instructions.

### 4.9 Programming Additional Miscellaneous Features Using JWS Annotations and APIs

The following sections describe additional miscellaneous features you can program by specifying particular JWS annotations in your JWS file or using WebLogic web services APIs:

- Section 4.9.1, "Sending Binary Data Using MTOM/XOP"
- Section 4.9.2, "Streaming SOAP Attachments"
- Section 4.9.3, "Using SOAP 1.2"
- Section 4.9.4, "Specifying that Operations Run Inside of a Transaction"
- Section 4.9.5, "Getting the HttpServletRequest/Response Object"
4.9.1 Sending Binary Data Using MTOM/XOP

SOAP Message Transmission Optimization Mechanism/XML-binary Optimized Packaging (MTOM/XOP) describes a method for optimizing the transmission of XML data of type xs:base64Binary in SOAP messages. When the transport protocol is HTTP, MIME attachments are used to carry that data while at the same time allowing both the sender and the receiver direct access to the XML data in the SOAP message without having to be aware that any MIME artifacts were used to marshal the xs:base64Binary data. The binary data optimization process involves encoding the binary data, removing it from the SOAP envelope, compressing it and attaching it to the MIME package, and adding references to that package in the SOAP envelope.

The MTOM specification does not require that, when MTOM is enabled, the web service run time use XOP binary optimization when transmitting base64binary data. Rather, the specification allows the run time to choose to do so. This is because in certain cases the run time may decide that it is more efficient to send base64binary data directly in the SOAP Message; an example of such a case is when transporting small amounts of data in which the overhead of conversion and transport consumes more resources than just inlining the data as is. The WebLogic web services implementation for MTOM for JAX-RPC service, however, always uses MTOM/XOP when MTOM is enabled.

Support for MTOM/XOP in WebLogic JAX-RPC web services is implemented using the pre-packaged WS-Policy file Mtom.xml. WS-Policy files follow the WS-Policy specification, described at http://www.w3.org/TR/ws-policy; this specification provides a general purpose model and XML syntax to describe and communicate the policies of a web service, in this case the use of MTOM/XOP to send binary data. The installation of the pre-packaged Mtom.xml WS-Policy file in the types section of the web service WSDL is as follows (provided for your information only; you cannot change this file):

```xml
<wsp:Policy wsu:Id="myService_policy">
  <wsp:ExactlyOne>
    <wsp:All>
      <wsoma:OptimizedMimeSerialization
    </wsp:All>
  </wsp:ExactlyOne>
</wsp:Policy>
```

When you deploy the compiled JWS file to WebLogic Server, the dynamic WSDL will automatically contain the following snippet that references the MTOM WS-Policy file; the snippet indicates that the web service uses MTOM/XOP:

```xml
<wsdl:binding name="BasicHttpBinding_IMtomTest"
  type="i0:IMtomTest">
  <wsp:PolicyReference URI="#myService_policy" />
  <soap:binding transport="http://schemas.xmlsoap.org/soap/http" />
</wsdl:binding>
```

You can associate the Mtom.xml WS-Policy file with a web service at development-time by specifying the @Policy metadata annotation in your JWS file. Be sure you also specify the attachToWsdl=true attribute to ensure that the dynamic WSDL includes the required reference to the Mtom.xml file; see the example below.

You can associate the Mtom.xml WS-Policy file with a web service at deployment time by modifying the WSDL to add the Policy to the types section just before deployment.
In addition, you can attach the file at run time using by the WebLogic Server Administration Console; for details, see “Attach a WS-Policy file to a web service” in the Oracle WebLogic Server Administration Console Online Help. This section describes how to use the JWS annotation.

**Note:** In this release of WebLogic Server, the only supported Java data type when using MTOM/XOP is byte[]; other binary data types, such as image, are not supported.

In addition, this release of WebLogic Server does not support using MTOM with deprecated 9.x security policies.

To send binary data using MTOM/XOP, follow these steps:

1. Use the WebLogic-specific @weblogic.jws.Policy annotation in your JWS file to specify that the pre-packaged Mtom.xml file should be applied to your web service, as shown in the following simple JWS file (relevant code shown in bold):

   ```java
   package examples.webservices.mtom;
   import javax.jws.WebMethod;
   import javax.jws.WebService;
   import weblogic.jws.WLHttpTransport;
   import weblogic.jws.Policy;
   @WebService(name="MtomPortType",
               serviceName="MtomService",
               targetNamespace="http://example.org")
   @WLHttpTransport(contextPath="mtom",
                     serviceUri="MtomService",
                     portName="MtomServicePort")
   @Policy(uri="policy:Mtom.xml", attachToWsdl=true)
   public class MtomImpl {
       @WebMethod
       public String echoBinaryAsString(byte[] bytes) {
           return new String(bytes);
       }
   }
   ```

2. Use the Java byte[] data type in your web service operations as either a return value or input parameter whenever you want the resulting SOAP message to use MTOM/XOP to send or receive the binary data. See the implementation of the echoBinaryAsString operation above for an example; this operation simply takes as input an array of byte and returns it as a String.

3. The WebLogic web services run time has built in MTOM/XOP support which is enabled if the WSDL for which the clientgen Ant task generates client-side artifacts specifies MTOM/XOP support. In your client application itself, simply invoke the operations as usual, using byte[] as the relevant data type.

See the SOAP Message Transmission Optimization Mechanism specification at http://www.w3.org/TR/2005/REC-soap12-mtom-20050125 for additional information about the MTOM/XOP feature itself as well as the version of the specification supported by WebLogic JAX-RPC web services.

### 4.9.2 Streaming SOAP Attachments

Using the @weblogic.jws.StreamAttachments JWS annotation, you can specify that a web service use a streaming API when reading inbound SOAP messages that include attachments, rather than the default behavior in which the service reads the entire
message into memory. This feature increases the performance of web services whose SOAP messages are particular large.

See "weblogic.jws.StreamAttachments" in the WebLogic Web Services Reference for Oracle WebLogic Server for an example of specifying that attachments should be streamed.

### 4.9.3 Using SOAP 1.2

WebLogic web services use, by default, Version 1.1 of Simple Object Access Protocol (SOAP) as the message format when transmitting data and invocation calls between the web service and its client. WebLogic web services support both SOAP 1.1 and the newer SOAP 1.2, and you are free to use either version.

To specify that the web service use Version 1.2 of SOAP, use the class-level @weblogic.jws.Binding annotation in your JWS file and set its single attribute to the value Binding.Type.SOAP12, as shown in the following example (relevant code shown in bold):

```java
package examples.webservices.soap12;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Binding;
@WebService(name="SOAP12PortType",
serviceName="SOAP12Service",
targetNamespace="http://example.org")
@WLHttpTransport(contextPath="soap12",
serviceUri="SOAP12Service",
portName="SOAP12ServicePort")
@Binding(Binding.Type.SOAP12)
/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic Web Service with a single operation: sayHello. The class uses SOAP 1.2 as its binding.
 */
public class SOAP12Impl {
    @WebMethod()
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: " + message + ";";
    }
}
```

Other than set this annotation, you do not have to do anything else for the web service to use SOAP 1.2, including changing client applications that invoke the web service; the WebLogic web services run time takes care of all the rest.

See "weblogic.jws.Binding" in the WebLogic Web Services Reference for Oracle WebLogic Server for additional information about this annotation.

### 4.9.4 Specifying that Operations Run Inside of a Transaction

When a client application invokes a WebLogic web service operation, the operation invocation takes place outside the context of a transaction, by default. If you want the operation to run inside a transaction, specify the @weblogic.jws.Transactional annotation in your JWS file, and set the boolean value attribute to true, as shown in the following example (relevant code shown in bold):

```java
package examples.webservices.transactional;
```
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Transactional;

@WebService(name="TransactionPojoPortType",
            serviceName="TransactionPojoService",
            targetNamespace="http://example.org")
@WLHttpTransport(contextPath="transactionsPojo",
                 serviceUri="TransactionPojoService",
                 portName="TransactionPojoPort")
/**
 * This JWS file forms the basis of simple WebLogic
 * Web Service with a single operation: sayHello. The operation executes
 * as part of a transaction.
 *
 */
public class TransactionPojoImpl {
    @WebMethod()
    @Transactional(value=true)
    public String sayHello(String message) {
        System.out.println("sayHello:" + message);
        return "Here is the message: \\
               '" + message + \\
               ";
    }
}

If you want all operations of a web service to run inside of a transaction, specify the
@Transactional annotation at the class-level. If you want only a subset of the
operations to be transactional, specify the annotation at the method-level. If there is a
conflict, the method-level value overrides the class-level.

See "weblogic.jws.Transactional" in the WebLogic Web Services Reference for Oracle
WebLogic Server for information about additional attributes.

4.9.5 Getting the HttpServletRequest/Response Object

If your web service uses HTTP as its transport protocol, you can use the
"weblogic.wsee.connection.transport.servlet.HttpTransportUtils" API in the
Java API Reference for Oracle WebLogic Server to get the
javax.servlet.http.HttpServletRequest and
javax.servlet.http.HttpServletResponse objects from the JAX-RPC
ServletEndpointContext object, as shown in the following example (relevant code
shown in bold and explained after the example):

package examples.webservices.http_transport_utils;
import javax.xml.rpc.server.ServiceLifecycle;
import javax.xml.rpc.server.ServletEndpointContext;
import javax.xml.rpc.ServiceException;
import javax.servlet.http.HttpServletRequest;
import javax.servlet.http.HttpServletResponse;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
import weblogic.wsee.connection.transport.servlet.HttpTransportUtils;

@WebService(name="HttpTransportUtilsPortType",
            serviceName="HttpTransportUtilsService",
            targetNamespace="http://example.org")
@WLHttpTransport(contextPath="servlet", serviceUri="HttpTransportUtils",
                 portName="HttpTransportUtilsPort")
public class HttpTransportUtilsImpl implements ServiceLifecycle {

    private ServletEndpointContext wsctx = null;

public void init(Object context) throws ServiceException {
    System.out.println("ServletEndpointContext inited...");
    wsctx = (ServletEndpointContext)context;
}
public void destroy() {
    System.out.println("ServletEndpointContext destroyed...");
    wsctx = null;
}
@WebMethod()
public String getServletRequestAndResponse() {
    HttpServletRequest request =
        HttpTransportUtils.getHttpServletRequest(wsctx.getMessageContext());
    HttpServletResponse response =
        HttpTransportUtils.getHttpServletResponse(wsctx.getMessageContext());
    System.out.println("HttpTransportUtils API used successfully.");
    return "HttpTransportUtils API used successfully";
}

The important parts of the preceding example are as follows:

- Import the required JAX-RPC and Servlet classes:
  
  ```java
  import javax.xml.rpc.server.ServiceLifecycle;
  import javax.xml.rpc.server.ServletEndpointContext;
  import javax.xml.rpc.ServiceException;
  import javax.servlet.http.HttpServletRequest;
  import javax.servlet.http.HttpServletResponse;
  ```

- Import the WebLogic `HttpTransportUtils` class:
  ```java
  import weblogic.wsee.connection.transport.servlet.HttpTransportUtils;
  ```

- Because you will be querying the JAX-RPC message context, your JWS file must explicitly implement `ServiceLifecycle`:
  ```java
  public class HttpTransportUtilsImpl implements ServiceLifecycle
  ```

- Create a variable of data type `ServletContext`:
  ```java
  private ServletEndpointContext wsctx = null;
  ```

- Because the JWS file implements `ServiceLifecycle`, you must also implement the `init` and `destroy` lifecycle methods:
  ```java
  public void init(Object context) throws ServiceException {
      System.out.println("ServletEndpointContext inited...");
      wsctx = (ServletEndpointContext)context;
  }
  public void destroy() {
      System.out.println("ServletEndpointContext destroyed...");
      wsctx = null;
  }
  ```

- Finally, in the method that implements the web service operation, use the `ServletEndpointContext` object to get the `HttpServletRequest` and `HttpServletResponse` objects:
  ```java
  HttpServletRequest request =
      HttpTransportUtils.getHttpServletRequest(wsctx.getMessageContext());
  HttpServletResponse response =
      HttpTransportUtils.getHttpServletResponse(wsctx.getMessageContext());
  ```
4.10 JWS Programming Best Practices

The following list provides some best practices when programming the JWS file:

- When you create a document-literal-bare web service, use the @WebParam JWS annotation to ensure that all input parameters for all operations of a given web service have a unique name. Because of the nature of document-literal-bare web services, if you do not explicitly use the @WebParam annotation to specify the name of the input parameters, WebLogic Server creates one for you and run the risk of duplicating the names of the parameters across a web service.

- In general, document-literal-wrapped web services are the most interoperable type of web service.

- Use the @WebResult JWS annotation to explicitly set the name of the returned value of an operation, rather than always relying on the hard-coded name return, which is the default name of the returned value if you do not use the @WebResult annotation in your JWS file.

- Use SOAPFaultExceptions in your JWS file if you want to control the exception information that is passed back to a client application when an error is encountered while invoking a the web service.

- Even though it is not required, Oracle recommends you always specify the portName attribute of the WebLogic-specific @WLHttpTransport annotation in your JWS file. If you do not specify this attribute, the jwsc Ant task will generate a port name for you when generating the WSDL file, but this name might not be very user-friendly. A consequence of this is that the getXXX() method you use in your client applications to invoke the web service will not be very well-named. To ensure that your client applications use the most user-friendly methods possible when invoking the web service, specify a relevant name of the web service port by using the portName attribute.
This chapter describes the data binding and the data types (both built-in and user-defined) that are supported for WebLogic web services for WebLogic Server 12.1.3 using Java API for XML-based RPC (JAX-RPC).

This chapter includes the following sections:

- Overview of Data Binding
- Supported Built-In Data Types
- Supported User-Defined Data Types

### 5.1 Overview of Data Binding

With the emergence of XML as the standard for exchanging data across disparate systems, web service applications need a way to access documents that are in XML format directly from the Java application. Specifically, the XML content needs to be converted to a format that is readable by the Java application. *Data binding* describes the conversion of data between its XML and Java representations.

As in previous releases, WebLogic web services support a full set of built-in XML Schema, Java, and SOAP types, as specified by the JAX-RPC specification, described at [http://java.net/projects/jax-rpc/](http://java.net/projects/jax-rpc/), that you can use in your web service operations without performing any additional programming steps. Built-in data types are those such as `integer`, `string`, and `time`.

Additionally, you can use a variety of user-defined XML and Java data types, including Apache XmlBeans (in package `org.apache.xmlbeans`), as input parameters and return values of your web service. User-defined data types are those that you create from XML Schema or Java building blocks, such as `<xsd:complexType>` or `JavaBeans`. The WebLogic web services Ant tasks, such as `jwsc` and `clientgen`, automatically generate the data binding artifacts needed to convert the user-defined data types between their XML and Java representations. The XML representation is used in the SOAP request and response messages, and the Java representation is used in the JWS that implements the web service.
5.2 Supported Built-In Data Types

The following sections describe the built-in data types supported by WebLogic web services and the mapping between their XML and Java representations. As long as the data types of the parameters and return values of the back-end components that implement your web service are in the set of built-in data types, WebLogic Server automatically converts the data between XML and Java.

If, however, you use user-defined data types, then you must create the data binding artifacts that convert the data between XML and Java. WebLogic Server includes the jwsc and wsdlc Ant tasks that can automatically generate the data binding artifacts for most user-defined data types. See Section 5.3, "Supported User-Defined Data Types" for a list of supported XML and Java data types.

5.2.1 XML-to-Java Mapping for Built-in Data Types

The following table lists the supported XML Schema data types (target namespace http://www.w3.org/2001/XMLSchema) and their corresponding Java data types.

For a list of the supported user-defined XML data types, see Section 5.2.2, "Java-to-XML Mapping for Built-In Data Types."

<table>
<thead>
<tr>
<th>XML Schema Data Type</th>
<th>Equivalent Java Data Type (lower case indicates a primitive data type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>byte</td>

<td>java.util.Calendar</td>
</tr>
<tr>
<td>base64Binary</td>
<td>byte[]</td>
</tr>
</tbody>
</table>

Note: As of WebLogic Server 9.1, using XMLBeans 1.x data types (in other words, extensions of com.bea.xml.XmlObject) as parameters or return types of a WebLogic web service is deprecated. New applications should use XMLBeans 2.x data types.

If a web service uses XMLBeans that are compiled with the -noupa option, then -Dweblogic.wsee.bind.setCompileNoUpaRule=true flag is required to be set in the WebLogic server startup script to ensure the web service deploys successfully. Otherwise, deployment will fail with the following error: cos-nonambig: Content model violates the unique particle attribution rule.

</tbody>
</table>
If your XML or Java data type is not listed in these tables, and it is not one of the built-in data types listed in Section 5.2, "Supported Built-In Data Types," then you must create the user-defined data type artifacts manually.

5.3.1 Supported XML User-Defined Data Types

The following table lists the XML Schema data types supported by the jwsc and wsdlc Ant tasks and their equivalent Java data type or mapping mechanism.

For details and examples of the data types, see the JAX-RPC specification at http://java.net/projects/jax-rpc/.

<table>
<thead>
<tr>
<th>XML Schema Data Type</th>
<th>Equivalent Java Data Type or Mapping Mechanism</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
<tr>
<td>Additionally, generics are not supported when used as a parameter or return value. For example, the following Java method cannot be exposed as a public operation:</td>
<td></td>
</tr>
<tr>
<td>public ArrayList&lt;String&gt; echoGeneric(ArrayList&lt;String&gt; in) { return in; }</td>
<td></td>
</tr>
</tbody>
</table>
Developing JAX-RPC Web Service Clients

This chapter describes how to develop WebLogic web service clients using Java API for XML-based RPC (JAX-RPC) for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of JAX-RPC Web Service Clients
- Invoking a Web Service from a Java SE Client
- Invoking a Web Service from Another Web Service
- Using a Standalone Client JAR File When Invoking Web Services
- Using a Proxy Server When Invoking a Web Service
- Client Considerations When Redeploying a Web Service
- WebLogic Web Services Stub Properties
- Setting the Character Encoding For the Response SOAP Message

Note: The following sections do not include information about invoking message-secured web services; for that topic, see "Updating a Client Application to Invoke a Message-Secured Web Service" in Securing WebLogic Web Services for Oracle WebLogic Server.

6.1 Overview of JAX-RPC Web Service Clients

Invoking a web service refers to the actions that a client application performs to use the web service. Client applications that invoke web services can be written using any technology: Java, Microsoft .NET, and so on.

There are two types of client applications:

- Java SE client—In its simplest form, a Java SE client is a Java program that has the `Main` public class that you invoke with the `java` command.

- Java EE component deployed to WebLogic Server—In this type of client application, the web service runs inside a Java Platform, Enterprise Edition (Java EE) Version 5 component deployed to WebLogic Server, such as an EJB, servlet, or another web service. This type of client application, therefore, runs inside a WebLogic Server container.

You can invoke a web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for standalone Java applications that are running in an environment where WebLogic Server libraries are not available, see Section 6.4, "Using a Standalone
**Overview of JAX-RPC Web Service Clients**

The sections that follow describe how to use Oracle’s implementation of the JAX-RPC specification to invoke a web service from a Java client application. You can use this implementation to invoke web services running on any application server, both WebLogic and non-WebLogic. In addition, you can create a client that runs as part of a WebLogic Server, or a standalone client that runs in an environment where WebLogic Server libraries are not available.

In addition to the command-line tools described in this section, you can use an IDE, such as Oracle JDeveloper, for proxy generation and testing. For more information, see "Using Oracle IDEs to Build Web Services" in *Understanding WebLogic Web Services for Oracle WebLogic Server*.

---

### 6.1.1 Invoking Web Services Using JAX-RPC

The Java API for XML based RPC (JAX-RPC) is a specification that defines the APIs used to invoke a web service. WebLogic Server implements the JAX-RPC specification.

The following table briefly describes the core JAX-RPC interfaces and classes.

<table>
<thead>
<tr>
<th>javax.xml.rpc Interface or Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service</td>
<td>Main client interface.</td>
</tr>
<tr>
<td>ServiceFactory</td>
<td>Factory class for creating Service instances.</td>
</tr>
<tr>
<td>Stub</td>
<td>Base class of the client proxy used to invoke the operations of a web service.</td>
</tr>
<tr>
<td>Call</td>
<td>Used to dynamically invoke a web service.</td>
</tr>
<tr>
<td>JAXRPCException</td>
<td>Exception thrown if an error occurs while invoking a web service.</td>
</tr>
</tbody>
</table>

---

### 6.1.2 Examples of Clients That Invoke Web Services

WebLogic Server optionally includes examples of creating and invoking WebLogic web services in the `EXAMPLES_HOME/wl_server/examples/src/examples/webservices` directory, where `EXAMPLES_HOME` represents the directory in which the WebLogic Server code examples are configured. The default path is `ORACLE_HOME\user_projects\applications`. For detailed instructions on how to build and run the examples, open the `EXAMPLES_HOME/wl_server/docs/index.html` Web page in your browser and expand the WebLogic Server Examples->Examples->API->Web Services node. For more information, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.
6.2 Invoking a Web Service from a Java SE Client

**Note:** As described in this section, you can invoke a web service from any Java SE or Java EE application running on WebLogic Server (with access to the WebLogic Server classpath). For information about support for standalone Java applications that are running in an environment where WebLogic Server libraries are not available, see Section 6.4, "Using a Standalone Client JAR File When Invoking Web Services".

The following table summarizes the main steps to create a Java SE client that invokes a web service.

**Note:** It is assumed that you use Ant in your development environment to build your client application, compile Java files, and so on, and that you have an existing `build.xml` file that you want to update with web services client tasks. For general information about using Ant in your development environment, see Section 3.5, "Creating the Basic Ant build.xml File." For a full example of a `build.xml` file used in this section, see Section 6.2.5, "Sample Ant Build File for a Java Client."

<table>
<thead>
<tr>
<th>#</th>
<th>Step Description</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set up the environment.</td>

<td>See Section 6.2.4, &quot;Compiling and Running the Client Application.&quot;</td>
</tr>
</tbody>
</table>
6.2.1 Using the clientgen Ant Task To Generate Client Artifacts

The clientgen WebLogic web services Ant task generates, from an existing WSDL file, the client artifacts that client applications use to invoke both WebLogic and non-WebLogic web services. These artifacts include:

- The Java class for the JAX-RPC Stub and Service interface implementations for the particular web service you want to invoke.
- The Java class for any user-defined XML Schema data types included in the WSDL file.
- The JAX-RPC mapping deployment descriptor file which contains information about the mapping between the Java user-defined data types and their corresponding XML Schema types in the WSDL file.
- A client-side copy of the WSDL file.

For additional information about the clientgen Ant task, such as all the available attributes, see "Ant Task Reference" in the WebLogic Web Services Reference for Oracle WebLogic Server.

Update your build.xml file, adding a call to the clientgen Ant task, as shown in the following example:

```xml
<taskdef name="clientgen" class="weblogic.wsee.tools.anttasks.ClientGenTask" />
<target name="build-client">
  <clientgen
    wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="clientclasses"
    packageName="examples.webservices.simple_client"
    type="JAXRPC"/>
</target>
```

Before you can execute the clientgen WebLogic web service Ant task, you must specify its full Java classname using the standard taskdef Ant task.

You must include the wsdl and destDir attributes of the clientgen Ant task to specify the WSDL file from which you want to create client-side artifacts and the directory into which these artifacts should be generated. The packageName attribute is optional; if you do not specify it, the clientgen task uses a package name based on the targetNamespace of the WSDL. The type is also optional; if not specified, it defaults to JAXRPC.

In this example, the package name is set to the same package name as the client application, examples.webservices.simple_client. If you set the package name to one that is different from the client application, you would need to import the appropriate class files. For example, if you defined the package name as examples.webservices.complex, you would need to import the following class files in the client application:

```java
import examples.webservices.complex.BasicStruct;
import examples.webservices.complex.ComplexPortType;
import examples.webservices.complex.ComplexService;
```
If the WSDL file specifies that user-defined data types are used as input parameters or return values of web service operations, `clientgen` automatically generates a JavaBean class that is the Java representation of the XML Schema data type defined in the WSDL. The JavaBean classes are generated into the `destDir` directory.

**Note:** The package of the Java user-defined data type is based on the XML Schema of the data type in the WSDL, which is different from the package name of the JAX-RPC stubs.

For a full sample `build.xml` file that contains additional targets from those described in this procedure, such as `clean`, see Section 6.2.5, "Sample Ant Build File for a Java Client."

To execute the `clientgen` Ant task, along with the other supporting Ant tasks, specify the `build-client` target at the command line:

```
prompt> ant build-client
```

See the `clientclasses` directory to view the files and artifacts generated by the `clientgen` Ant task.

### 6.2.2 Getting Information About a Web Service

You need to know the name of the web service and the signature of its operations before you write your Java client application code to invoke an operation. There are a variety of ways to find this information.

The best way to get this information is to use the `clientgen` Ant task to generate the web service-specific JAX-RPC stubs and look at the generated `.java` files. These files are generated into the directory specified by the `destDir` attribute, with subdirectories corresponding to either the value of the `packageName` attribute, or, if this attribute is not specified, to a package based on the `targetNamespace` of the WSDL.

- The `ServiceName.java` source file contains the `getPortName()` methods for getting the web service port, where `ServiceName` refers to the name of the web service and `PortName` refers to the name of the port. If the web service was implemented with a JWS file, the name of the web service is the value of the `serviceName` attribute of the `@WebService` JWS annotation and the name of the port is the value of the `portName` attribute of the `@WLHttpTransport` annotation.

- The `PortType.java` file contains the method signatures that correspond to the public operations of the web service, where `PortType` refers to the port type of the web service. If the web service was implemented with a JWS file, the port type is the value of the `name` attribute of the `@WebService` JWS annotation.

You can also examine the actual WSDL of the web service; see Section 3.10, "Browsing to the WSDL of the Web Service" for details about the WSDL of a deployed WebLogic web service. The name of the web service is contained in the `<service>` element, as shown in the following excerpt of the `TraderService` WSDL:

```
<service name="TraderService">
```

**Note:** The `clientgen` Ant task also provides the `destFile` attribute if you want the Ant task to automatically compile the generated Java code and package all artifacts into a JAR file. For details and an example, see "clientgen" in the WebLogic Web Services Reference for Oracle WebLogic Server.
The operations defined for this web service are listed under the corresponding <binding> element. For example, the following WSDL excerpt shows that the TraderService web service has two operations, buy and sell (for clarity, only relevant parts of the WSDL are shown):

```
<binding name="TraderServiceSoapBinding" ...>
  ...
</binding>
```

### 6.2.3 Writing the Java Client Application Code to Invoke a Web Service

In the following code example, a Java application invokes a web service operation. The client application takes a single argument: the WSDL of the web service. The application then uses standard JAX-RPC API code and the web service-specific implementation of the Service interface, generated by clientgen, to invoke an operation of the web service.

The example also shows how to invoke an operation that has a user-defined data type (examples.webservices.complex.BasicStruct) as an input parameter and return value. The clientgen Ant task automatically generates the Java code for this user-defined data type.

```java
package examples.webservices.simple_client;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
// import the BasicStruct class, used as a param and return value of the
// echoComplexType operation. The class is generated automatically by
// the clientgen Ant task.
import examples.webservices.complex.BasicStruct;
/**
 * This is a simple Java client application that invokes the
 * the echoComplexType operation of the ComplexService web service.
 */
public class Main {
  public static void main(String[] args)
    throws ServiceException, RemoteException {
    ComplexService service = new ComplexService_Impl (args[0] + "?WSDL" );
    ComplexPortType port = service.getComplexServicePort();
    BasicStruct in = new BasicStruct();
    in.setIntValue(999);
    in.setStringValue("Hello Struct");
    BasicStruct result = port.echoComplexType(in);
    System.out.println("echoComplexType called. Result: "+ result.getIntValue()
      + ", " + result.getStringValue());
  }
}
```
In the preceding example:

- The following code shows how to create a ComplexPortType stub:

```java
ComplexService service = new ComplexService_Impl (args[0] + "?WSDL");
ComplexPortType port = service.getComplexServicePort();
```

The ComplexService_Impl stub factory implements the JAX-RPC Service interface. The constructor of ComplexService_Impl creates a stub based on the provided WSDL URI (args[0] + "?WSDL"). The getComplexServicePort() method is used to return an instance of the ComplexPortType stub implementation.

- The following code shows how to invoke the echoComplexType operation of the ComplexService web service:

```java
BasicStruct result = port.echoComplexType(in);
```

The echoComplexType operation returns the user-defined data type called BasicStruct.

The method of your application that invokes the web service operation must throw or catch java.rmi.RemoteException and javax.xml.rpc.ServiceException, both of which are thrown from the generated JAX-RPC stubs.

### 6.2.4 Compiling and Running the Client Application

Add javac tasks to the build-client target in the build.xml file to compile all the Java files (both of your client application and those generated by clientgen) into class files, as shown by the bold text in the following example:

```xml
<target name="build-client">
  <clientgen
    wsdl="http://${wls.hostname}:${wls.port}/complex/ComplexService?WSDL"
    destDir="clientclasses"
    packageName="examples.webservices.simple_client"
    type="JAXRPC"/>
  <javac
    srcdir="clientclasses"
    destdir="clientclasses"
    includes="**/*.java"/>
  <javac
    srcdir="src"
    destdir="clientclasses"
    includes="examples/webservices/simple_client/*.java"/>
</target>
```

In the example, the first javac task compiles the Java files in the clientclasses directory that were generated by clientgen, and the second javac task compiles the Java files in the examples/webservices/simple_client subdirectory of the current directory; where it is assumed your Java client application source is located.

In the preceding example, the clientgen-generated Java source files and the resulting compiled classes end up in the same directory (clientclasses). Although this might be adequate for prototyping, it is often a best practice to keep source code (even generated code) in a different directory from the compiled classes. To do this, set the destdir for both javac tasks to a directory different from the srcdir directory. You must also copy the following clientgen-generated files from clientgen's destination directory to javac's destination directory, keeping the same subdirectory hierarchy in the destination:
packageName/ServiceName_internaldd.xml
packageName/ServiceName_java_wsdll_mapping.xml
packageName/ServiceName_saved_wsdll.wsdl

where packageName refers to the subdirectory hierarchy that corresponds to the package of the generated JAX-RPC stubs and ServiceName refers to the name of the web service.

To run the client application, add a run target to the build.xml that includes a call to the java task, as shown below:

```xml
<target name="run">
  <java
    fork="true"
    classname="examples.webServices.simple_client.Main"
    failonerror="true" >
    <classpath refid="client.class.path"/>
    <arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService" />
  </java>
</target>
```

The path task adds the clientclasses directory to the CLASSPATH. The run target invokes the Main application, passing it the URL of the deployed web service as its single argument.

See Section 6.2.5, "Sample Ant Build File for a Java Client" for a full sample build.xml file that contains additional targets from those described in this procedure, such as clean.

Rerun the build-client target to regenerate the artifacts and recompile into classes, then execute the run target to invoke the echoStruct operation:

```
prompt> ant build-client run
```

You can use the build-client and run targets in the build.xml file to iteratively update, rebuild, and run the Java client application as part of your development process.

### 6.2.5 Sample Ant Build File for a Java Client

The following example shows a complete build.xml file for generating and compiling a Java client. See Section 6.2.1, "Using the clientgen Ant Task To Generate Client Artifacts" and Section 6.2.4, "Compiling and Running the Client Application" for explanations of the sections in bold.

```xml
<project name="webservices-simple_client" default="all">
  <!-- set global properties for this build -->
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="example-output" value="output" />
  <property name="clientclass-dir" value="${example-output}/clientclass" />
  <path id="client.class.path">
    <pathelement path="${clientclass-dir}"/>
    <pathelement path="${java.class.path}"/>
  </path>
  <taskdef name="clientgen"
    classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
  <target name="clean">
    <delete quiet="true" includeemptydirs="false">
      <fileset dir="clientclass" path="*" recursive="false" includeemptydirs="false" />
      <fileset dir="build" path="*" recursive="false" includeemptydirs="false" />
    </delete>
  </target>
  <target name="clientgen">
    <clientgen srcdir="examples/" destdir="clientclass" classes="examples.webServices.simple_client" />
  </target>
  <target name="compile">
    <javac srcdir="clientclass" destdir="build" includeantruntime="false" />
  </target>
  <target name="run" depends="build">
    <java
      fork="true"
      classname="examples.webServices.simple_client.Main"
      failonerror="true" >
      <classpath refid="client.class.path"/>
      <arg line="http://${wls.hostname}:${wls.port}/complex/ComplexService" />
    </java>
  </target>
</project>
```
6.3 Invoking a Web Service from Another Web Service

Invoking a web service from within a WebLogic web service is similar to invoking one from another Java application, as described in Section 6.2, "Invoking a Web Service from a Java SE Client." However, instead of using the clientgen Ant task to generate the JAX-RPC stubs of the web service to be invoked, you use the <clientgen> child element of the <jws> element, inside the jwsc Ant task that compiles the invoking web service. In the JWS file that invokes the other web service, however, you still use the same standard JAX-RPC APIs to get Service and PortType instances to invoke the web service operations.

It is assumed that you have read and understood Section 6.2, "Invoking a Web Service from a Java SE Client." It is also assumed that you use Ant in your development environment to build your client application, compile Java files, and so on, and that you have an existing build.xml that builds a web service that you want to update to invoke another web service.

The following list describes the changes you must make to the build.xml file that builds your client web service, which will invoke another web service. See Section 6.3.1, "Sample build.xml File for a Web Service Client" for the full sample build.xml file:

- Add a <clientgen> child element to the <jws> element that specifies the JWS file that implements the web service that invokes another web service. Set the required wsdl attribute to the WSDL of the web service to be invoked. Set the required packageName attribute to the package into which you want the JAX-RPC client stubs to be generated.

The following list describes the changes you must make to the JWS file that implements the client web service; see Section 6.3.2, "Sample JWS File That Invokes a Web Service" for the full JWS file example.
Import the files generated by the `<clientgen>` child element of the `jwsc` Ant task. These include the JAX-RPC stubs of the invoked web service, as well as the Java representation of any user-defined data types used as parameters or return values in the operations of the invoked web service.

---

**Note:** The user-defined data types are generated into a package based on the XML Schema of the data type in the WSDL, *not* in the package specified by `clientgen`. The JAX-RPC stubs, however, use the package name specified by the `packageName` attribute of the `<clientgen>` element.

---

Update the method that contains the invoke of the web service to either throw or catch both `java.rmi.RemoteException` and `javax.xml.rpc.ServiceException`.

Get the Service and PortType JAX-RPC stubs implementation and invoke the operation on the port as usual; see Section 6.2.3, "Writing the Java Client Application Code to Invoke a Web Service" for details.

### 6.3.1 Sample build.xml File for a Web Service Client

The following sample build.xml file shows how to create a web service that itself invokes another web service; the relevant sections that differ from the build.xml for building a simple web service that does not invoke another web service are shown in **bold**.

The `build-service` target in this case is very similar to a target that builds a simple web service; the only difference is that the `jwsc` Ant task that builds the invoking web service also includes a `<clientgen>` child element of the `<jws>` element so that `jwsc` also generates the required JAX-RPC client stubs.

```xml
<project name="webservices-service_to_service" default="all">
  <!-- set global properties for this build -->
  <property name="wls.username" value="weblogic" />
  <property name="wls.password" value="weblogic" />
  <property name="wls.hostname" value="localhost" />
  <property name="wls.port" value="7001" />
  <property name="wls.server.name" value="myserver" />
  <property name="ear.deployed.name" value="ClientServiceEar" />
  <property name="example-output" value="output" />
  <property name="ear-dir" value="${example-output}/ClientServiceEar" />
  <property name="clientclass-dir" value="${example-output}/clientclasses" />
  <path id="client.class.path">
    <pathelement path="${clientclass-dir}"/>
    <pathelement path="${java.class.path}"/>
  </path>
  <taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />
  <taskdef name="clientgen"
    classname="weblogic.wsee.tools.anttasks.ClientGenTask" />
  <taskdef name="wldeploy"
    classname="weblogic.ant.taskdefs.management.WLDeploy"/>
  <target name="all" depends="clean,build-service,deploy,client"/>
  <target name="clean" depends="undeploy">
    <delete dir="${example-output}"/>
  </target>
  <target name="build-service">
    <jwsc
      srcdir="src"
      Note: The user-defined data types are generated into a package based on the XML Schema of the data type in the WSDL, *not* in the package specified by `clientgen`. The JAX-RPC stubs, however, use the package name specified by the `packageName` attribute of the `<clientgen>` element.
```
6.3.2 Sample JWS File That Invokes a Web Service

The following sample JWS file, called ClientServiceImpl.java, implements a web service called ClientService that has an operation that in turn invokes the echoComplexType operation of a web service called ComplexService. This operation has a user-defined data type (BasicStruct) as both a parameter and a return value. The relevant code is shown in bold and described after the example.
package examples.webservices.service_to_service;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;
// Import the BasicStruct data type, generated by clientgen and used
// by the ComplexService Web Service
import examples.webservices.complex.BasicStruct;
// Import the JAX-RPC Stubs for invoking the ComplexService Web Service.
// Stubs generated by clientgen
import examples.webservices.service_to_service.ComplexPortType;
import examples.webservices.service_to_service.ComplexService_Impl;
import examples.webservices.service_to_service.ComplexService;
@WebService(name="ClientPortType", serviceName="ClientService",
targetNamespace="http://examples.org")
@WLHttpTransport(contextPath="ClientService", serviceUri="ClientService",
portName="ClientServicePort")
public class ClientServiceImpl {
    @WebMethod()
    public String callComplexService(BasicStruct input, String serviceUrl)
        throws ServiceException, RemoteException {
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePort();
        // Create service and port stubs to invoke ComplexService
        ComplexService service = new ComplexService_Impl(serviceUrl + "?WSDL");
        ComplexPortType port = service.getComplexServicePortTypePort();
        // Invoke the echoComplexType operation of ComplexService
        BasicStruct result = port.echoComplexType(input);
        System.out.println("Invoked ComplexPortType.echoComplexType.");
        return "Invoke went okay! Here's the result: " + result.getIntValue() + ",
        " + result.getStringValue() + ";
    }
}

Follow these guidelines when programming the JWS file that invokes another web
service; code snippets of the guidelines are shown in bold in the preceding example:

- Import any user-defined data types that are used by the invoked web service. In this
  example, the ComplexService uses the BasicStruct JavaBean:

  import examples.webservices.complex.BasicStruct;

- Import the JAX-RPC stubs of the ComplexService web service; the stubs are
  generated by the <clientgen> child element of <jws>:

  import examples.webservices.service_to_service.ComplexPortType;
  import examples.webservices.service_to_service.ComplexService_Impl;
  import examples.webservices.service_to_service.ComplexService;

- Ensure that your client web service throws or catches ServiceException and
  RemoteException:

  throws ServiceException, RemoteException

- Create the JAX-RPC Service and PortType instances for the ComplexService:

  ComplexService service = new
ComplexService_Impl(serviceUrl + "?WSDL");
  ComplexPortType port = service.getComplexServicePortTypePort();
- Invoke the echoComplexType operation of ComplexService using the port you just instantiated:

```java
BasicStruct result = port.echoComplexType(input);
```

### 6.4 Using a Standalone Client JAR File When Invoking Web Services

It is assumed in this document that, when you invoke a web service using the client-side artifacts generated by the clientgen or wsdlc Ant tasks, you have the entire set of WebLogic Server classes in your CLASSPATH. If, however, your computer does not have WebLogic Server installed, you can still invoke a web service by using the standalone WebLogic web services client JAR file, as described in this section.

The standalone client JAR file supports basic client-side functionality, such as:

- Use with client-side artifacts created by both the clientgen Ant tasks
- Processing SOAP messages
- Using client-side SOAP message handlers
- Using MTOM
- Invoking JAX-RPC web services
- Using SSL

The standalone client JAR file does not, however, support invoking web services that use the following advanced features:

- Web services reliable SOAP messaging
- Message-level security (WS-Security)
- Conversations
- Asynchronous request-response
- Buffering
- JMS transport

To use the standalone WebLogic web services client JAR file with your client application, follow these steps:

1. Copy the file `ORACLE_HOME/wls/server/modules/clients/com.oracle.webservices.wls.jaxrpc-client.jar` from the computer hosting WebLogic Server to the client computer, where `ORACLE_HOME` is the directory you specified as Oracle Home when you installed Oracle WebLogic Server and `domainName` is the name of your domain.

2. Add the JAR file to your CLASSPATH.

---

**Note:** Ensure that your CLASSPATH includes the JAR file that contains the Ant classes (`ant.jar`) as a subset of the classes are required by the JAR file. This JAR file is typically located in the `lib` directory of the Ant distribution.
6.5 Using a Proxy Server When Invoking a Web Service

You can use a proxy server to proxy requests from a client application to an application server (either WebLogic or non-WebLogic) that hosts the invoked web service. You typically use a proxy server when the application server is behind a firewall. There are two ways to specify the proxy server in your client application: programmatically using the WebLogic HttpTransportInfo API or using system properties.

6.5.1 Using the HttpTransportInfo API to Specify the Proxy Server

You can programmatically specify within the Java client application itself the details of the proxy server that will proxy the web service invoke by using the standard java.net.* classes and the WebLogic-specific HttpTransportInfo API. You use the java.net classes to create a Proxy object that represents the proxy server, and then use the WebLogic API and properties to set the proxy server on the JAX-RPC stub, as shown in the following sample client that invokes the echo operation of the HttpProxySampleService web service. The code in bold is described after the example:

```java
package dev2dev.proxy.client;
import java.net.Proxy;
import java.net.InetSocketAddress;
import weblogic.wsee.connection.transport.http.HttpTransportInfo;
/**
 * Sample client to invoke a service through a proxy server via
 * programmatic API
 */
public class HttpProxySampleClient {
    public static void main(String[] args) throws Throwable{
        assert args.length == 5;
        String endpoint = args[0];
        String proxyHost = args[1];
        String proxyPort = args[2];
        String user = args[3];
        String pass = args[4];
        //create service and port
        HttpProxySampleService service = new HttpProxySampleService_Impl();
        HttpProxySamplePortType port = service.getHttpProxySamplePortTypeSoapPort();
        //set endpoint address
        ((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, endpoint);
        //set proxy server info
        Proxy p = new Proxy(Proxy.Type.HTTP, new  InetSocketAddress(proxyHost,
            Integer.parseInt(proxyPort)));
        HttpTransportInfo info = new HttpTransportInfo();
        info.setProxy(p);
        ((Stub)port)._setProperty("weblogic.wsee.connection.transportinfo",info);
        //set proxy-authentication info
        ((Stub)port)._setProperty("weblogic.webservice.client.proxyusername",user);
        ((Stub)port)._setProperty("weblogic.webservice.client.proxypassword",pass);
        //invoke
        String s = port.echo("Hello World!");
        System.out.println("echo: " + s);
    }
}
```

The sections of the preceding example to note are as follows:

- Import the required java.net.* classes:
import java.net.Proxy;
import java.net.InetSocketAddress;

■ Import the WebLogic HttpTransportInfo API:
import weblogic.wsee.connection.transport.http.HttpTransportInfo;

■ Create a Proxy object that represents the proxy server:
Proxy p = new Proxy(Proxy.Type.HTTP, new InetSocketAddress(proxyHost, Integer.parseInt(proxyPort)));

The proxyHost and proxyPort arguments refer to the host computer and port of the proxy server.

■ Create an HttpTransportInfo object and use the setProxy() method to set the proxy server information:
HttpTransportInfo info = new HttpTransportInfo();
info.setProxy(p);

■ Use the weblogic.wsee.connection.transportinfo WebLogic stub property to set the HttpTransportInfo object on the JAX-RPC stub:
((Stub)port)._setProperty("weblogic.wsee.connection.transportinfo",info);

■ Use weblogic.webservice.client.proxyusername and weblogic.webservice.client.proxypassword WebLogic-specific stub properties to specify the username and password of a user who is authenticated to access the proxy server:
((Stub)port)._setProperty("weblogic.webservice.client.proxyusername",user);
((Stub)port)._setProperty("weblogic.webservice.client.proxypassword",pass);

Alternatively, you can use the setProxyUsername() and setProxyPassword() methods of the HttpTransportInfo API to set the proxy username and password, as shown in the following example:
info.setProxyUsername("juliet".getBytes());
info.setProxyPassword("secret".getBytes());

6.5.2 Using System Properties to Specify the Proxy Server

To use system properties to specify the proxy server, write your client application in the standard way, and then specify system properties when you execute the client application.

You have a choice of using standard Java system properties or historical WebLogic properties. If the proxySet system property is set to false (proxySet=false), proxy properties will be ignored and no proxy will be used.

The following table summarizes the Java system properties. In this case, the proxySet system property must not be set.
Using a Proxy Server When Invoking a Web Service

The following excerpt from an Ant build script shows an example of setting Java system properties when invoking a client application called clients.InvokeMyService:

```xml
<target name="run-client">
  <java fork="true"
      classname="clients.InvokeMyService"
      failonerror="true">
    <classpath refid="client.class.path"/>
    <arg line="${http-endpoint}"/>
    <jvmarg line="-Dhttp.proxyHost=${proxy-host}
                   -Dhttp.proxyPort=${proxy-port}
                   -Dhttp.nonProxyHosts=${mydomain}"/>
  </java>
</target>
```

The following table summarizes the WebLogic system properties. In this case, the proxySet system property must be set to true.

**Table 6–3 Java System Properties Used to Specify Proxy Server**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http.proxyHost=proxyHost</td>
<td>Name of the host computer on which the proxy server is running. Use https.proxyHost for HTTP over SSL.</td>
</tr>
<tr>
<td>https.proxyHost=proxyHost</td>
<td></td>
</tr>
<tr>
<td>http.proxyPort=proxyPort</td>
<td>Port to which the proxy server is listening. Use https.proxyPort for HTTP over SSL.</td>
</tr>
<tr>
<td>https.proxyPort=proxyPort</td>
<td></td>
</tr>
<tr>
<td>http.nonProxyHosts=hostname</td>
<td>List of hosts that should be reached directly, bypassing the proxy. Separate each host name using a</td>
</tr>
<tr>
<td>hostname \ hostname \ ...</td>
<td></td>
</tr>
</tbody>
</table>

The following excerpt from an Ant build script shows an example of setting WebLogic system properties when invoking a client application called clients.InvokeMyService:

```xml
<target name="run-client">
  <java fork="true"
      classname="clients.InvokeMyService"
      failonerror="true">
    <classpath refid="client.class.path"/>
    <arg line="${http-endpoint}"/>
    <jvmarg line="-Dhttp.proxyHost=${proxy-host}
                   -Dhttp.proxyPort=${proxy-port}
                   -Dhttp.nonProxyHosts=${mydomain}"/>
  </java>
</target>
```

The following table summarizes the WebLogic system properties. In this case, the proxySet system property must be set to true.

**Table 6–4 WebLogic System Properties Used to Specify the Proxy Server**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxySet=true</td>
<td>Flag that specifies that the historical WebLogic proxy properties should be used.</td>
</tr>
<tr>
<td>proxyHost=proxyHost</td>
<td>Name of the host computer on which the proxy server is running.</td>
</tr>
<tr>
<td>proxyPort=proxyPort</td>
<td>Port to which the proxy server is listening.</td>
</tr>
<tr>
<td>weblogic.webservice.client.proxyusername=username</td>
<td>Username used to access the proxy server.</td>
</tr>
<tr>
<td>weblogic.webservice.client.proxypassword=password</td>
<td>Password used to access the proxy server.</td>
</tr>
</tbody>
</table>

The following excerpt from an Ant build script shows an example of setting WebLogic system properties when invoking a client application called clients.InvokeMyService:

```xml
<target name="run-client">
  <java fork="true"
      classname="clients.InvokeMyService"
      failonerror="true">
    <classpath refid="client.class.path"/>
    <arg line="${http-endpoint}"/>
    <jvmarg line="-Dhttp.proxyHost=${proxy-host}
                   -Dhttp.proxyPort=${proxy-port}
                   -Dhttp.nonProxyHosts=${mydomain}"/>
  </java>
</target>
```
6.6 Client Considerations When Redeploying a Web Service

WebLogic Server supports production redeployment, which means that you can deploy a new version of an updated WebLogic web service alongside an older version of the same web service.

WebLogic Server automatically manages client connections so that only new client requests are directed to the new version. Clients already connected to the web service during the redeployment continue to use the older version of the service until they complete their work, at which point WebLogic Server automatically retires the older web service. If the client is connected to a conversational or reliable web service, its work is considered complete when the existing conversation or reliable messaging sequence is explicitly ended by the client or because of a timeout.

You can continue using the old client application with the new version of the web service, as long as the following web service artifacts have not changed in the new version:

- WSDL that describes the web service
- WS-Policy files attached to the web service

If any of these artifacts have changed, you must regenerate the JAX-RPC stubs used by the client application by re-running the clientgen Ant task.

For example, if you change the signature of an operation in the new version of the web service, then the WSDL file that describes the new version of the web service will also change. In this case, you must regenerate the JAX-RPC stubs. If, however, you simply change the implementation of an operation, but do not change its public contract, then you can continue using the existing client application.

6.7 WebLogic Web Services Stub Properties

WebLogic Server provides a set of stub properties that you can set in the JAX-RPC Stub used to invoke a WebLogic web service. Use the Stub._setProperty() method to set the properties, as shown in the following example:

```java
((Stub)port)._setProperty(WLStub.MARSHAL_FORCE_INCLUDE_XSI_TYPE,"true");
```

Most of the stub properties are defined in the WLStub class. See "weblogic.wsee.jaxrpc.WLStub" in the Java API Reference for Oracle WebLogic Server for details.

The following table describes additional stub properties not defined in the WLStub class.
<table>
<thead>
<tr>
<th><strong>Table 6–5 Additional Stub Properties</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Stub Property</strong></td>
</tr>
<tr>
<td>weblogic.wsee.transport.connection.timeout</td>
</tr>
<tr>
<td>weblogic.wsee.transport.read.timeout</td>
</tr>
</tbody>
</table>
| weblogic.wsee.security.bst.serverVerifyCert | Specifies the certificate that the client application uses to validate the signed response from WebLogic Server. By default, WebLogic Server includes the certification used to validate in the response SOAP message itself; if this is not possible, then use this stub property to specify a different one.  
This stub property applies only to client applications that run inside of a WebLogic Server container, and not to standalone client applications.  
The value of the property is an object of data type java.security.cert.X509Certificate. |
| weblogic.wsee.security.bst.serverEncryptCert | Specifies the certificate that the client application uses to encrypt the request SOAP message sent to WebLogic Server.  
By default, the client application uses the public certificate published in the web service’s WSDL; if this is not possible, then use this stub property to specify a different one.  
This stub property applies only to client applications that run inside of a WebLogic Server container, and not to standalone client applications.  
The value of the property is an object of data type java.security.cert.X509Certificate. |
| weblogic.wsee.marshal.forceIncludeXsiType | Specifies that the SOAP messages for a web service operation invoke should include the XML Schema data type of each parameter. By default, the SOAP messages do not include the data type of each parameter.  
If you set this property to True, the elements in the SOAP messages that describe operation parameters will include an xsi:type attribute to specify the data type of the parameter, as shown in the following example:  

```xml
<soapenv:Envelope>  
  ...  
  <maxResults xsi:type="xs:int">10</maxResults>  
  ...  
</soapenv:Envelope>
```

By default (or if you set this property to False), the parameter element would look like the following example:  

```xml
<soapenv:Envelope>  
  ...  
  <maxResults>10</maxResults>  
  ...  
</soapenv:Envelope>
```

Valid values for this property are True and False; default value is False.
6.8 Setting the Character Encoding For the Response SOAP Message

Use the `weblogic.wsee.jaxrpc.WLStub.CHARACTER_SET_ENCODING` WLStub property to set the character encoding of the response (outbound) SOAP message. You can set it to the following two values:

- UTF-8
- UTF-16

The following code snippet from a client application shows how to set the character encoding to UTF-16:

```java
Simple port = service.getSimpleSoapPort();
((Stub) port)._setProperty(weblogic.wsee.jaxrpc.WLStub.CHARACTER_SET_ENCODING, 'UTF-16');
port.invokeMethod();
```

See "weblogic.wsee.jaxrpc.WLStub" in the Java API Reference for Oracle WebLogic Server for additional WLStub properties you can set.
Part II describes how to develop advanced features of WebLogic web services using Java API for XML-based RPC (JAX-RPC).

Sections include:

- Chapter 7, "Invoking a Web Service Using Asynchronous Request-Response"
- Chapter 8, "Using Web Services Reliable Messaging"
- Chapter 9, "Creating Conversational Web Services"
- Chapter 10, "Creating Buffered Web Services"
- Chapter 11, "Using the Asynchronous Features Together"
- Chapter 12, "Using Callbacks to Notify Clients of Events"
- Chapter 13, "Using JMS Transport as the Connection Protocol"
- Chapter 14, "Creating and Using SOAP Message Handlers"
- Chapter 15, "Using Database Web Services"
This chapter describes how to invoke a WebLogic Java API for XML-based RPC (JAX-RPC) web service using asynchronous request-response for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of the Asynchronous Request-Response Feature
- Using Asynchronous Request-Response: Main Steps
- Configuring the Host WebLogic Server Instance for the Asynchronous Web Service
- Writing the Asynchronous JWS File
- Updating the build.xml File When Using Asynchronous Request-Response
- Disabling The Internal Asynchronous Service
- Using Asynchronous Request Response With a Proxy Server

7.1 Overview of the Asynchronous Request-Response Feature

When you invoke a web service synchronously, the invoking client application waits for the response to return before it can continue with its work. In cases where the response returns immediately, this method of invoking the web service might be adequate. However, because request processing can be delayed, it is often useful for the client application to continue its work and handle the response later on, or in other words, use the asynchronous request-response feature of WebLogic web services.

You invoke a web service asynchronously only from a client running in a WebLogic web service, never from a stand-alone client application. The invoked web service does not change in any way, thus you can invoke any deployed web service (both WebLogic and non-WebLogic) asynchronously as long as the application server that hosts the web service supports the WS-Addressing specification at http://www.w3.org/Submission/2004/SUBM-ws-addressing-20040810/.

When implementing asynchronous request-response in your client, rather than invoking the operation directly, you invoke an asynchronous flavor of the same operation. (This asynchronous flavor of the operation is automatically generated by the jwsc Ant task.) For example, rather than invoking an operation called getQuote directly, you would invoke getQuoteAsync instead. The asynchronous flavor of the operation always returns void, even if the original operation returns a value. You then include methods in your client that handle the asynchronous response or failures when it returns later on. You put any business logic that processes the return value of
the web service operation invoke or a potential failure in these methods. You use both
naming conventions and JWS annotations to specify these methods to the JWS
compiler. For example, if the asynchronous operation is called getQuoteAsync, then
these methods might be called onGetQuoteAsyncResponse and
onGetQuoteAsyncFailure.

Note: For information about using asynchronous request-response
with other asynchronous features, such as web service reliable
messaging or buffering, see Chapter 11, "Using the Asynchronous
Features Together." This section describes how to use the
asynchronous request-response feature on its own.

The asynchronous request-response feature works only with HTTP;
you cannot use it with the HTTPS or JMS transport.

7.2 Using Asynchronous Request-Response: Main Steps

The following procedure describes how to create a client web service that
asynchronously invokes an operation in a different web service. The procedure shows
how to create the JWS file that implements the client web service from scratch; if you
want to update an existing JWS file, use this procedure as a guide.

For clarity, it is assumed in the procedure that:

■ The client web service is called StockQuoteClientService.

■ The StockQuoteClientService service is going to invoke the getQuote(String)
operation of the already-deployed StockQuoteService service whose WSDL is
found at the following URL:

It is further assumed that you have set up an Ant-based development environment
and that you have a working build.xml file to which you can add targets for running
the jwsc Ant task and deploying the generated service. For more information, see the
following sections:

■ "Examples for JAX-RPC Web Service Developers" on page 2-1

■ "Developing JAX-RPC Web Services" on page 3-1

■ "Programming the JWS File" on page 4-1

■ "Developing JAX-RPC Web Service Clients" on page 6-1

Table 7–1 Steps to Use Asynchronous Request-Response

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Configure the WebLogic Server instances.</td>
<td>Configure the asynchronous response service, as described in Section 7.3, &quot;Configuring the Host WebLogic Server Instance for the Asynchronous Web Service&quot;.</td>
</tr>
<tr>
<td>2</td>
<td>Create a new JWS file, or update an existing one, that implements the StockQuoteClientService web service.</td>
<td>Use your favorite IDE or text editor. See Section 7.4, &quot;Writing the Asynchronous JWS File&quot;.</td>
</tr>
</tbody>
</table>
When you invoke the `StockQuoteClientService` web service, which in turn invokes the `StockQuoteService` web service, the second invoke will be asynchronous rather than synchronous.

### 7.3 Configuring the Host WebLogic Server Instance for the Asynchronous Web Service

Configuring the WebLogic Server instance on which the asynchronous web service is deployed involves configuring JMS resources, such as JMS servers and modules, that are used internally by the web services runtime.

You can configure these resources manually or you can use the Configuration Wizard to extend the WebLogic Server domain using a web services-specific extension template. Using the Configuration Wizard greatly simplifies the required configuration steps; for details, see “Configuring Your Domain For Web Services Features” on page 3-2.

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Update your <code>build.xml</code> file to compile the JWS file that implements the <code>StockQuoteClientService</code>.</td>
<td>You will add a <code>&lt;clientgen&gt;</code> child element to the <code>jwsc</code> Ant task so as to automatically generate the asynchronous flavor of the web service operations you are invoking. See Section 7.5, &quot;Updating the <code>build.xml</code> File When Using Asynchronous Request-Response&quot;.</td>
</tr>
<tr>
<td>4</td>
<td>Run the Ant target to build the <code>StockQuoteClientService</code>.</td>
<td>For example: <code>prompt&gt; ant build-clientService</code></td>
</tr>
<tr>
<td>5</td>
<td>Deploy the <code>StockQuoteClientService</code> web service as usual.</td>
<td>See “Deploying and Undeploying WebLogic Web Services” on page 3-14.</td>
</tr>
</tbody>
</table>

When you invoke the `StockQuoteClientService` web service, which in turn invokes the `StockQuoteService` web service, the second invoke will be asynchronous rather than synchronous.

**Notes:** Alternatively, you can use WLST to configure the resources. For information about using WLST to extend the domain, see "Configuring Existing Domains" in *Understanding the WebLogic Scripting Tool*.

A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

If you prefer to configure the resources manually, perform the following steps.
7.4 Writing the Asynchronous JWS File

The following example shows a simple JWS file that implements a web service called StockQuoteClient that has a single method, asyncOperation, that in turn asynchronously invokes the getQuote method of the StockQuote service. The Java code in bold is described Section 7.4.1, "Coding Guidelines for Invoking a Web Service Asynchronously". See Section 7.4.3, "Example of a Synchronous Invoke" to see how the

---

Table 7–2 Steps to Configure Host WebLogic Server Instance Manually for the Asynchronous Web Service

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1  | Invoke the WebLogic Server Administration Console for the domain that contains the host WebLogic Server instance. | To invoke the WebLogic Server Administration Console in your browser, enter the following URL: http://host:port/console where  
  ■ host refers to the computer on which the Administration Server is running.  
  ■ port refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001.  
  See "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server. |
| 2  | Create a JMS Server.                                                 | Create a JMS Server. If a JMS server already exists, you can use it if you do not want to create a new one.  
  See "Create JMS servers" in Oracle WebLogic Server Administration Console Online Help.                                                                                                                                         |
| 3  | Create JMS module and define queue.                                 | Create a JMS module, and then define a JMS queue in the module. If a JMS module already exists, you can use it if you do not want to create a new one. Target the JMS queue to the JMS server you created in the preceding step. Be sure you specify that this JMS queue is local, typically by setting the local JNDI name.  
  See "Create JMS system modules" and "Create queues in a system module" in Oracle WebLogic Server Administration Console Online Help.  
  If you want the asynchronous web service to use the default web services queue, set the JNDI name of the JMS queue to weblogic.wsee.DefaultQueue.  
  Clustering Considerations:  
  If you are using the web service asynchronous feature in a cluster, you must:  
  ■ Create a local JMS queue, rather than a distributed queue, when creating the JMS queue.  
  ■ Explicitly target this JMS queue to each server in the cluster. |
| 4  | Create a Work Manager.                                              | Define a Work Manager named weblogic.wsee.mdb.DispatchPolicy, which is used by the asynchronous request-response feature, by default.  
  See "Create global Work Managers" in Oracle WebLogic Server Administration Console Online Help.                                                                                                                                   |
| 5  | Tune your domain environment, as required. (Optional)               | Review "Tuning Heavily Loaded Systems to Improve Web Service Performance" in Tuning Performance of Oracle WebLogic Server.                                                                                                                                                                |
asynchronous invoke differs from a synchronous invoke of the same operation.

```java
package examples.webservices.async_req_res;

import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;
import weblogic.jws.AsyncResponse;
import weblogic.jws.AsyncFailure;
import weblogic.wsee.async.AsyncPreCallContext;
import weblogic.wsee.async.AsyncCallContextFactory;
import weblogic.wsee.async.AsyncPostCallContext;
import javax.jws.WebService;
import javax.jws.WebMethod;
import examples.webservices.async_req_res.StockQuotePortType;
import java.rmi.RemoteException;

@WebService(name="StockQuoteClientPortType",
serviceName="StockQuoteClientService",
targetNamespace="http://examples.org/")
@WLHttpTransport(contextPath="asyncClient",
serviceUri="StockQuoteClient",
portName="StockQuoteClientServicePort")
/**
 * Client Web Service that invokes the StockQuote Service asynchronously.
 */
public class StockQuoteClientImpl {

private StockQuotePortType port;

@WebMethod
public void asyncOperation (String symbol, String userName) throws RemoteException {
    AsyncPreCallContext apc = AsyncCallContextFactory.getAsyncPreCallContext();
    apc.setProperty("userName", userName);
    try {
        port.getQuoteAsync(apc, symbol);
        System.out.println("in getQuote method of StockQuoteClient WS");
    } catch (RemoteException re) {
        System.out.println("RemoteException thrown");
        throw new RuntimeException(re);
    }
}

@AsyncResponse(target="port", operation="getQuote")
public void onGetQuoteAsyncResponse(AsyncPostCallContext apc, int quote) {
    // Get the userName property we set on AsyncPreCallContext
```
Writing the Asynchronous JWS File

```java
String userName = (String)apc.getProperty("userName");
System.out.println("-------------------");
System.out.println(username + " Got quote " + quote);
System.out.println("-------------------");
}

@AsyncFailure(target="port", operation="getQuote")
public void onGetQuoteAsyncFailure(AsyncPostCallContext apc, Throwable e) {
    System.out.println("-------------------");
e.printStackTrace();
    System.out.println("-------------------");
}

7.4.1 Coding Guidelines for Invoking a Web Service Asynchronously

The following guidelines for invoking an operation asynchronously correspond to the Java code shown in **bold** in the example described in Section 7.4, "Writing the Asynchronous JWS File". These guidelines are in addition to the standard ones for creating JWS files. See Section 7.4.3, "Example of a Synchronous Invoke" to see how the asynchronous invoke differs from a synchronous invoke of the same operation.

To invoke an operation asynchronously in your JWS file:

- Import the following WebLogic-specific JWS annotations related to the asynchronous request-response feature:

  ```java
  import weblogic.jws.ServiceClient;
  import weblogic.jws.AsyncResponse;
  import weblogic.jws.AsyncFailure;
  ```

- Import the JAX-RPC stub, created later by the `<jwsc>` Ant task, of the port type of the web service you want to invoke. The stub package is specified by the `packageName` attribute of the `<clientgen>` child element of `<jwsc>`, and the name of the stub is determined by the WSDL of the invoked web service.

  ```java
  import examples.webservices.async_req_res.StockQuotePortType;
  ```

- Import the asynchronous pre- and post-call context WebLogic APIs:

  ```java
  import weblogic.wsee.async.AsyncCallContextFactory;
  import weblogic.wsee.async.AsyncPreCallContext;
  import weblogic.wsee.async.AsyncPostCallContext;
  ```

  For more information about asynchronous pre- and post-call context, see Section 7.4.2, "Using Asynchronous Pre- and Post-call Contexts". See the "weblogic.wsee.async" package in *Java API Reference for Oracle WebLogic Server* for additional reference information about these APIs.

- In the body of the JWS file, use the required `@ServiceClient` JWS annotation to specify the WSDL, name, and port of the web service you will be invoking asynchronously. You specify this annotation at the field-level on a variable, whose data type is the JAX-RPC port type of the web service you are invoking.

  ```java
  @ServiceClient(
      serviceName="StockQuoteService",
      portName="StockQuote")
  ```

  private StockQuotePortType port;
```
When you annotate a variable (in this case, `port`) with the `@ServiceClient` annotation, the web services runtime automatically initializes and instantiates the variable, preparing it so that it can be used to invoke another web service asynchronously.

- In the method of the JWS file which is going to invoke the `getQuote` operation asynchronously, get a pre-call asynchronous context using the context factory:

  ```java
  AsyncPreCallContext apc =
  AsyncCallContextFactory.getAsyncPreCallContext();
  
  For more information about asynchronous pre- and post-call context, see Section 7.4.2, "Using Asynchronous Pre- and Post-call Contexts".

- Use the `setProperty` method of the pre-call context to create a property to store the username:

  ```java
  apc.setProperty("userName", userName);
  
  For more information about asynchronous pre- and post-call context, see Section 7.4.2, "Using Asynchronous Pre- and Post-call Contexts".

- Using the stub you annotated with the `@ServiceClient` annotation, invoke the operation (in this case, `getQuote`). Instead of invoking it directly, however, invoke the asynchronous flavor of the operation, which has `Async` added on to the end of its name. The asynchronous flavor always returns `void`. Pass the asynchronous context as the first parameter:

  ```java
  port.getQuoteAsync(apc, symbol);
  
  For each operation you will be invoking asynchronously, create a method called `onOperationnameAsyncResponse`, where `Operationname` refers to the name of the operation, with initial letter always capitalized. The method must return `void`, and have two parameters: the post-call asynchronous context and the return value of the operation you are invoking. Annotate the method with the `@AsyncResponse` JWS annotation; use the `target` attribute to specify the variable whose datatype is the JAX-RPC stub and the `operation` attribute to specify the name of the operation you are invoking asynchronously. Inside the body of the method, put the business logic that processes the value returned by the operation. Use the `getProperty` method of the post-call context to get the property that was set by pre-call context before invoking the asynchronous method:

  ```java
  @AsyncResponse(target="port", operation="getQuote")
  public void onGetQuoteAsyncResponse(AsyncPostCallContext apc, int quote) {
      // Get the userName property we set on AsyncPreCallContext
      String userName = (String)apc.getProperty("userName");
      System.out.println("-------------------");
      System.out.println("Got quote "+ quote);
      System.out.println("-------------------");
  }
  
  For more information about asynchronous pre- and post-call context, see Section 7.4.2, "Using Asynchronous Pre- and Post-call Contexts".

- For each operation you will be invoking asynchronously, create a method called `onOperationnameAsyncFailure`, where `Operationname` refers to the name of the operation, with initial letter capitalized. The method must return `void`, and have two parameters: the post-call asynchronous context and a `Throwable` object, the superclass of all exceptions to handle any type of exception thrown by the invoked operation. Annotate the method with the `@AsyncFailure` JWS annotation; use the `target` attribute to specify the variable whose datatype is the JAX-RPC stub and
the operation attribute to specify the name of the operation you are invoking asynchronously. Inside the method, you can determine the exact nature of the exception and write appropriate Java code.

```java
@AsyncFailure(target="port", operation="getQuote")
public void onGetQuoteAsyncFailure(AsyncPostCallContext apc, Throwable e) {
    System.out.println("-------------------");
    e.printStackTrace();
    System.out.println("-------------------");
}
```

**Note:** You are not required to use the @AsyncResponse and @AsyncFailure annotations, although it is a good practice because it clears up any ambiguity and makes your JWS file clean and understandable. However, in the rare use case where you want one of the onXXX methods to handle the asynchronous response or failure from two (or more) stubs that are invoking operations from two different web services that have the same name, then you should explicitly NOT use these annotations. Be sure that the name of the onXXX methods follow the correct naming conventions exactly, as described above.

---

### 7.4.2 Using Asynchronous Pre- and Post-call Contexts

The AsyncPreCallContext and AsyncPostCallContext APIs describe asynchronous contexts that you can use in your web service for a variety of reasons. For example:

- Set a property in the pre-context so that the method that handles the asynchronous response can distinguish between different asynchronous calls.
- Get and set contextual variables, such as the name of the user invoking the operation, their password, and so on.
- Get the name of the JAX-RPC stub that invoked a method asynchronously; and to set a time-out interval on the context.

To use asynchronous pre- and post-call contexts:

1. Import the asynchronous pre- and post-call context WebLogic APIs:
   ```java
   import weblogic.wsee.async.AsyncCallContextFactory;
   import weblogic.wsee.async.AsyncPreCallContext;
   import weblogic.wsee.async.AsyncPostCallContext;
   ```

2. In the method of the JWS file that is going to invoke the asynchronous operation, get a pre-call asynchronous context using the context factory. For example:
   ```java
   AsyncPreCallContext apc =
   AsyncCallContextFactory.getAsyncPreCallContext();
   ```

3. Use the pre-call context methods to operate on the asynchronous context before the asynchronous method is called. The following example uses the `setProperty` method of the pre-call context to create a property that stores the username:
   ```java
   apc.setProperty("userName", userName);
   ```

4. Use the post-call context methods to operate on the asynchronous context after the asynchronous method is called. The following example uses the `getProperty`
method of the post-call context to get the property that was set by pre-call context before invoking the asynchronous method:

```java
String userName = (String)apc.getProperty("userName");
```

### 7.4.3 Example of a Synchronous Invoke

The following example shows a JWS file that invokes the `getQuote` operation of the `StockQuote` web service synchronously. The example is shown only so you can compare it with the corresponding asynchronous invoke shown in Section 7.4, “Writing the Asynchronous JWS File”.

```java
package examples.webservices.async_req_res;

import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;
import javax.jws.WebService;
import javax.jws.WebMethod;
import java.rmi.RemoteException;

@WebService(name="SyncClientPortType",
            serviceName="SyncClientService",
            targetNamespace="http://examples.org/")
@WLHttpTransport(contextPath="syncClient",
            serviceUri="SyncClient",
            portName="SyncClientPort")
/**
 * Normal service-to-service client that invokes StockQuote service
 * synchronously.
 */
public class SyncClientImpl {

    @ServiceClient(wsdlLocation="http://localhost:7001/async/StockQuote?WSDL",
                   serviceName="StockQuoteService", portName="StockQuote")
    private StockQuotePortType port;

    @WebMethod
    public void nonAsyncOperation(String symbol) throws RemoteException {

        int quote = port.getQuote(symbol);

        System.out.println("-------------------");
        System.out.println("Got quote " + quote);
        System.out.println("-------------------");

    }
}
```
7.5 Updating the build.xml File When Using Asynchronous Request-Response

To update a build.xml file to generate the JWS file that invokes a web service operation asynchronously, add taskdefs and a build-clientService target that looks something like the following; see the description after the example for details:

```xml
<taskdef name="jwsc"
   classname="weblogic.wsee.tools.anttasks.JwscTask" />

<target name="build-clientService">

   <jwsc
      enableAsyncService="true"
      srcdir="src"
      destdir="${clientService-ear-dir}" >

      <jws file="examples/webservices/async_req_res/StockQuoteClientImpl.java" >

         <clientgen
            wsdl="http://${wls.hostname}:${wls.port}/async/StockQuote?WSDL"
            packageName="examples.webservices.async_req_res"/>

      </jws>

   </jwsc>

</target>
```

Use the taskdef Ant task to define the full classname of the jwsc Ant tasks.

Update the jwsc Ant task that compiles the client web service to include a <clientgen> child element of the <jws> element so as to generate and compile the JAX-RPC stubs for the deployed StockQuote web service. The jwsc Ant task automatically packages them in the generated WAR file so that the client web service can immediately access the stubs. By default, the jwsc Ant task in this case generates both synchronous and asynchronous flavors of the web service operations in the JAX-RPC stubs. You do this because the StockQuoteClientImpl JWS file imports and uses one of the generated classes.

7.6 Disabling The Internal Asynchronous Service

By default, every WebLogic Server instance deploys an internal asynchronous web service that handles the asynchronous request-response feature. To specify that you do not want to deploy this internal service, start the WebLogic Server instance using the -Dweblogic.wsee.skip.async.response=true Java system property.

One reason for disabling the asynchronous service is if you use a WebLogic Server instance as a Web proxy to a WebLogic cluster. In this case, asynchronous messages will never get to the cluster, as required, because the asynchronous service on the proxy server consumes them instead. For this reason, you must disable the asynchronous service on the proxy server using the system property.

For details on specifying Java system properties to configure WebLogic Server, see "Specifying Java Options for a WebLogic Server Instance" in Administering Server Startup and Shutdown for Oracle WebLogic Server.
7.7 Using Asynchronous Request Response With a Proxy Server

Client applications that use the asynchronous request-response feature might not invoke the operation directly, but rather, use a proxy server. Reasons for using a proxy include the presence of a firewall or the deployment of the invoked web service to a cluster.

In this case, the WebLogic Server instance that hosts the invoked web service must be configured with the address and port of the proxy server. If your web service is deployed to a cluster, you must configure every server in the cluster.

This procedure describes how to create a network channel, the primary configurable WebLogic Server resource for managing network connection. Network channels enable you to provide a consistent way to access the front-end address of a cluster. For more information about network channels, see "Understanding Network Channels" in *Administering Server Environments for Oracle WebLogic Server*.

For each server instance:

1. Create a network channel for the protocol you use to invoke the web service. You must name the network channel `weblogic-wsee-proxy-channel-XXX`, where `XXX` refers to the protocol. For example, to create a network channel for HTTPS, call it `weblogic-wsee-proxy-channel-https`.

   See "Configure custom network channels" in *Oracle WebLogic Server Administration Console Online Help* for general information about creating a network channel.

2. Configure the network channel, updating the **External Listen Address** and **External Listen Port** fields with the address and port of the proxy server, respectively.
This chapter describes web services reliable messaging for WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of Web Service Reliable Messaging
- Using Web Service Reliable Messaging: Main Steps
- Configuring the Destination WebLogic Server Instance
- Configuring the Source WebLogic Server Instance
- Creating the Web Service Reliable Messaging WS-Policy File
- Programming Guidelines for the Reliable JWS File
- Configuring Reliable Messaging for a Reliable Web Service
- Programming Guidelines for the JWS File That Invokes a Reliable Web Service
- Updating the build.xml File for a Client of a Reliable Web Service
- Using Reliable Messaging With MTOM
- Client Considerations When Redeploying a Reliable Web Service
- Using Reliable Messaging With a Proxy Server

Note: Web service reliable messaging requires the use of asynchronous request-response feature of WebLogic web services. Before proceeding, you should familiarize yourself with the concepts described in Chapter 7, "Invoking a Web Service Using Asynchronous Request-Response.”

8.1 Overview of Web Service Reliable Messaging

Web service reliable messaging is a framework that enables an application running on one application server to reliably invoke a web service running on another application server, assuming that both servers implement the WS-ReliableMessaging specification. Reliable is defined as the ability to guarantee message delivery between the two Web Services in the presence of software component, system, or network failures.
Overview of Web Service Reliable Messaging

WebLogic web services conform to the WS-ReliableMessaging specification (June 2007) at [http://docs.oasis-open.org/ws-rx/wsrm/200702/wsrn-1.1-spec-os-01.pdf](http://docs.oasis-open.org/ws-rx/wsrm/200702/wsrn-1.1-spec-os-01.pdf), which describes how two web services running on different application servers can communicate reliably. In particular, the specification describes an interoperable protocol in which a message sent from a source endpoint (or client web service) to a destination endpoint (or web service whose operations can be invoked reliably) is guaranteed either to be delivered, according to one or more delivery assurances, or to raise an error.

A reliable WebLogic web service provides the following delivery assurances.

### Table 8–1 Delivery Assurances for Reliable Messaging

<table>
<thead>
<tr>
<th>Delivery Assurance</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>At Most Once</td>
<td>Messages are delivered at most once, without duplication. It is possible that some messages may not be delivered at all.</td>
</tr>
<tr>
<td>At Least Once</td>
<td>Every message is delivered at least once. It is possible that some messages are delivered more than once.</td>
</tr>
<tr>
<td>Exactly Once</td>
<td>Every message is delivered exactly once, without duplication.</td>
</tr>
<tr>
<td>In Order</td>
<td>Messages are delivered in the order that they were sent. This delivery assurance can be combined with one of the preceding three assurances.</td>
</tr>
</tbody>
</table>

**Note:** Web services reliable messaging requires the use of asynchronous messages. Clients cannot invoke a reliable service synchronously. When invoking a reliable stub method, you must use the async signature—for example, xyzAsync() instead of xyz(). For clients that create SOAP messages directly, the request message is created with non-anonymous ReplyTo address.

You cannot set ReplyTo to the anonymous URI. Any attempt to invoke an operation on a JAX-RPC-based reliable service (either by invoking the sync stub signature or sending a request with anonymous ReplyTo) will result in a runtime exception.

This document describes how to create the reliable and client web services and how to configure the two WebLogic Server instances to which the web services are deployed. See the WS-ReliableMessaging specification for detailed documentation about the architecture of web service reliable messaging (see [http://docs.oasis-open.org/ws-rx/wsrm/200702/wsrn-1.1-spec-os-01.pdf](http://docs.oasis-open.org/ws-rx/wsrm/200702/wsrn-1.1-spec-os-01.pdf)).
8.1.1 Using WS-Policy to Specify Reliable Messaging Policy Assertions

WebLogic web services use WS-Policy files to enable a destination endpoint to describe and advertise its web service reliable messaging capabilities and requirements. The WS-Policy files are XML files that describe features such as the version of the supported WS-ReliableMessaging specification and quality of service requirements. The WS-Policy specification (http://www.w3.org/TR/ws-policy/) provides a general purpose model and syntax to describe and communicate the policies of a web service.

WebLogic Server includes pre-packaged WS-Policy files that contain typical reliable messaging assertions, as described in Appendix A, "Pre-Packaged WS-Policy Files for Reliable Messaging." If the pre-packaged WS-Policy files do not suit your needs, you must create your own WS-Policy file. See Section 8.5, "Creating the Web Service Reliable Messaging WS-Policy File" for details. See "Web Service Reliable Messaging Policy Assertion Reference" in the WebLogic Web Services Reference for Oracle WebLogic Server for reference information about the reliable messaging policy assertions.

8.1.2 Managing the Life Cycle of the Reliable Message Sequence

The following figure shows a one-way reliable message exchange.

![Figure 8–1  Web Service Reliable Message Exchange](image)

A reliable message sequence is used to track the progress of a set of messages that are exchanged reliably between an RM source and RM destination. A sequence can be used to send zero or more messages, and is identified by a string identifier. This identifier is used to reference the sequence when using reliable messaging.

The web service client application sends a message for reliable delivery which is transmitted by the RM source to the RM destination. The RM destination acknowledges that the reliable message has been received and delivers it to the web service application. The message may be retransmitted by the RM source until the acknowledgement is received.

A web service client sends messages to a target web service by invoking methods on a JAX-RPC stub. The stub is associated with the port type of the reliable web service and represents a programmatic interface to that service. WebLogic stores the identifier for the reliable message sequence within this stub. This causes the reliable message sequence to be connected to a single JAX-RPC stub. All messages that are sent using a given stub will use the same reliable messaging sequence, regardless of the number of messages that are sent using the stub. The JAX-RPC stub is created by the <clientgen> child element of the "jwsc" Ant task.

Because WebLogic Server retains resources associated with the reliable sequence, it is recommended that you take steps to release these resources in a timely fashion.
WebLogic Server provides a utility class, `weblogic.wsee.reliability.WsrmUtils`, for use with the web service reliable messaging. Use this class to perform common tasks such as set configuration options, get the sequence id, and terminate a reliable sequence.

Under normal circumstances, a reliable sequence should be retained until all messages have been sent and acknowledged by the RM destination. To facilitate the timely and proper termination of a sequence, it is recommended that you identify the final message in a reliable message sequence. Doing so indicates you are done sending messages to the RM destination and that WebLogic Server can begin looking for the final acknowledgement before automatically terminating the reliable sequence. Indicate the final message using the `weblogic.wsee.reliability.WsrmUtils.setFinalMessage()` method, passing the JAX-RPC stub being used to send messages to the RM destination.

When you identify a final message, after all messages up to and including the final message are acknowledged, the reliable message sequence is terminated, and all resources are released. Otherwise, the sequence is terminated automatically after the configured sequence expiration period is reached.

Although not recommended, you can terminate the sequence regardless of whether all messages have been acknowledged using the `terminateSequence()` method. Once issued, no further reliable messages can be sent on this stub.

---

**Note:** The JAX-RPC stub is not fully initialized until shortly after the first method is invoked on the reliable web service. When the first method is invoked, the RM source sends a `CreateSequence` message to the RM destination requesting that the RM destination create and register the reliable sequence. The RM destination, at some later time, responds with the ID for the newly created sequence. Until this response ID is received, the RM source cannot have any further communication with the RM destination and the JAX-RPC stub representing the target service at the RM destination cannot be used.

You cannot perform operations on the reliable message sequence until it is fully initialized; otherwise an error is returned. Use the `weblogic.wsee.reliability.WsrmUtils.waitForSequenceInitialization()` method to monitor whether or not the reliable message sequence has been initialized. Once the reliable sequence is initialized, this method returns the ID of the sequence.

---

For more information about the `WsrmUtils` utility class, see "weblogic.wsee.reliability.WsrmUtils" in [Java API Reference for Oracle WebLogic Server](https://docs.oracle.com/en/middleware/weblogic-server/12.1.3.0.1/api/index.html).

### 8.2 Using Web Service Reliable Messaging: Main Steps

Configuring reliable messaging for a WebLogic web service requires standard JMS tasks such as creating JMS servers and Store and Forward (SAF) agents, as well as web service-specific tasks, such as adding additional JWS annotations to your JWS file. Optionally, you create WS-Policy files that describe the reliable messaging capabilities of the reliable web service if you do not use the pre-packaged ones.

If you are using the WebLogic client APIs to invoke a reliable web service, the client application must run on WebLogic Server. Thus, configuration tasks must be performed on both the source WebLogic Server instance on which the web service that
includes client code to invoke the reliable web service reliably is deployed, as well as the destination WebLogic Server instance on which the reliable web service itself is deployed.

The following table summarizes the steps to create a reliable web service, as well as a client web service that invokes an operation of the reliable web service. The procedure describes how to create the JWS files that implement the two web services from scratch; if you want to update existing JWS files, use this procedure as a guide. The procedure also describes how to configure the source and destination WebLogic Server instances.

**Table 8–2  Steps to Create and Invoke a Reliable Web Service**

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1  | Configure the destination and source WebLogic Server instances.    | You will deploy the reliable web service to the destination WebLogic Server instance. For information about configuring the destination WebLogic Server instance, see Section 8.3, "Configuring the Destination WebLogic Server Instance".  
You will deploy the client web service that invokes the reliable web service to the source WebLogic Server instance. For information about configuring the source WebLogic Server instance, see Section 8.4, "Configuring the Source WebLogic Server Instance". |
| 2  | Create the WS-Policy file. (Optional)                               | Using your favorite XML or plain text editor, optionally create a WS-Policy file that describes the reliable messaging capabilities of the web service running on the destination WebLogic Server. For details about creating your own WS-Policy file, see Section 8.5, "Creating the Web Service Reliable Messaging WS-Policy File".  
This step is not required if you plan to use one of the WS-Policy files that are included in WebLogic Server; see Appendix A, "Pre-Packaged WS-Policy Files for Reliable Messaging," for more information. |
| 3  | Create or update the JWS file that implements the reliable web service. | This web service will be deployed to the destination WebLogic Server instance. See Section 8.6, "Programming Guidelines for the Reliable JWS File". |
| 4  | Update the build.xml file that is used to compile the reliable web services. | Update your build.xml file to include a call to the jwsc Ant task which will compile the reliable JWS file into a web service.  
See "Running the jwsc WebLogic Web Services Ant Task" on page 3-7 for general information about using the jwsc task. |
| 5  | Compile and deploy the reliable JWS file.                          | Compile the reliable JWS file by calling the appropriate target and deploy to the destination WebLogic Server. For example:  
prompt> ant build-mainService deploy-mainService |
| 6  | Configure the reliable web service.                                 | Configure the reliable messaging options for the reliable web service using the WebLogic Server Administration Console. See Section 8.7, "Configuring Reliable Messaging for a Reliable Web Service". |
| 7  | Create or update the JWS file that implements the client web service. | This service invokes the reliable web service and will be deployed to the source WebLogic Server. See Section 8.8, "Programming Guidelines for the JWS File That Invokes a Reliable Web Service". |
| 8  | Update the build.xml file that is used to compile the client web service. | See Section 8.9, "Updating the build.xml File for a Client of a Reliable Web Service". |
8.2.1 Prerequisites

It is assumed that you have completed the following tasks:

- You have created the destination and source WebLogic Server instances.
- You have set up an Ant-based development environment for each environment.
- You have working build.xml files that you can edit, for example, to add targets for running the jwsc Ant task and deploying the generated reliable web service.

For more information, see "Developing JAX-RPC Web Services" on page 3-1.

8.3 Configuring the Destination WebLogic Server Instance

To configure the WebLogic Server instance on which the reliable web service is deployed, configure the JMS and store and forward (SAF) resources.

You can configure these resources manually or you can use the Configuration Wizard to extend the WebLogic Server domain using a web services-specific extension template. Using the Configuration Wizard greatly simplifies the required configuration steps; for details, see "Configuring Your Domain For Web Services Features" on page 3-2.
Configuring the Destination WebLogic Server Instance

Note: Alternatively, you can use WLST to configure the resources. For information about using WLST to extend the domain, see "Configuring Existing Domains" in Understanding the WebLogic Scripting Tool.

A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

If you prefer to configure the resources manually, perform the following steps.

Table 8–3 Steps to Configure the Destination WebLogic Server Instance Manually

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1  | Invoke the WebLogic Server Administration Console for the domain that contains the destination WebLogic Server. | To invoke the WebLogic Server Administration Console in your browser, enter the following URL: http://host:port/console where
  - host refers to the computer on which the Administration Server is running.
  - port refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001. See "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server. |
| 2  | Create persistent file store. (Optional)                             | Optionally create a persistent store (file or JDBC) that will be used by the destination WebLogic Server to store internal web service reliable messaging information. You can use an existing one, or the default store that always exists, if you do not want to create a new one. See "Create file stores" in Oracle WebLogic Server Administration Console Online Help. |
| 3  | Create a JMS Server.                                                | Create a JMS Server. If a JMS server already exists, you can use it if you do not want to create a new one. See "Create JMS servers" in Oracle WebLogic Server Administration Console Online Help. |
Table 8–3  (Cont.) Steps to Configure the Destination WebLogic Server Instance Manually

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 4  | Create JMS module and define queue.     | Create a JMS module, and then define a JMS queue in the module. If a JMS module already exists, you can use it if you do not want to create a new one. Target the JMS queue to the JMS server you created in the preceding step. Be sure you specify that this JMS queue is local, typically by setting the local JNDI name. Take note of the JNDI name you define for the JMS queue because you will later use it when you program the JWS file that implements your reliable web service. See "Create JMS system modules" and "Create queues in a system module" in Oracle WebLogic Server Administration Console Online Help. **Clustering Considerations:** If you are using the web service reliable messaging feature in a cluster, you must:  
  - Create a local JMS queue, rather than a distributed queue, when creating the JMS queue.  
  - Explicitly target this JMS queue to each server in the cluster. |
| 5  | Create a store and forward (SAF) agent. | You can use an existing one if you do not want to create a new one. When you create the SAF agent:  
  - Set the Agent Type field to Both to enable both sending and receiving agents.  
  - Be sure to target the SAF agent by clicking Next on the first assistant page to view the Select targets page (rather than clicking Finish).  
**Clustering Considerations:** If you are using reliable messaging within a cluster, you must target the SAF agent to the cluster. See "Create Store-and-Forward agents" in Oracle WebLogic Server Administration Console Online Help. |
| 6  | Tune your domain environment, as required. (Optional) | Review “Tuning Heavily Loaded Systems to Improve web service Performance” in Tuning Performance of Oracle WebLogic Server. |
| 7  | Restart the server.                     | In order for the configuration changes to take effect, you must restart the server, as described in “Starting and Stopping Servers” in Administering Server Startup and Shutdown for Oracle WebLogic Server. |

### 8.4 Configuring the Source WebLogic Server Instance

Configuring the WebLogic Server instance on which the client web service is deployed involves configuring JMS and store and forward (SAF) resources.

You can configure these resources manually or you can use the Configuration Wizard to extend the WebLogic Server domain using a web services-specific extension template. Using the Configuration Wizard greatly simplifies the required configuration steps; for details, see “Configuring Your Domain For Web Services Features” on page 3-2.
Notes: Alternatively, you can use WLST to configure the resources. For information about using WLST to extend the domain, see "Configuring Existing Domains" in Understanding the WebLogic Scripting Tool.

A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

If you prefer to configure the resources manually, perform the following steps.

Table 8–4 Steps to Configure the Source WebLogic Server Instance

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1   | Invoke the WebLogic Server Administration Console for the domain that contains the source WebLogic Server. | To invoke the WebLogic Server Administration Console in your browser, enter the following URL:  
   http://host:port/console  
   where  
   - host refers to the computer on which the Administration Server is running.  
   - port refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001.  
   See "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server. |
| 2   | Create persistent file store. (Optional)                             | Optionally create a persistent store (file or JDBC) that will be used by the source WebLogic Server to store internal web service reliable messaging information. You can use an existing one, or the default store that always exists, if you do not want to create a new one.  
   See "Create file stores" in Oracle WebLogic Server Administration Console Online Help. |
| 3   | Create as store and forward (SAF) agent.                            | You can use an existing one if you do not want to create a new one.  
   When you create the SAF agent, set the Agent Type field to Both to enable both sending and receiving agents.  
   See "Create Store-and-Forward agents" in Oracle WebLogic Server Administration Console Online Help. |
| 6   | Tune your domain environment, as required. (Optional)               | Review "Tuning Heavily Loaded Systems to Improve web service Performance" in Tuning Performance of Oracle WebLogic Server. |
| 7   | Restart the server.                                                  | In order for the configuration changes to take effect, you must restart the server, as described in "Starting and Stopping Servers" in Administering Server Startup and Shutdown for Oracle WebLogic Server. |

8.5 Creating the Web Service Reliable Messaging WS-Policy File

A WS-Policy file is an XML file that contains policy assertions that comply with the WS-Policy specification. In this case, the WS-Policy file contains web service reliable messaging policy assertions.
WebLogic Server includes pre-packaged WS-Policy files that contain typical reliable messaging assertions that you can use if you do not want to create your own WS-Policy file. The pre-packaged WS-Policy files are listed in the following table.

<table>
<thead>
<tr>
<th>Pre-packaged WS-Policy File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultReliability1.1.xml</td>
<td>Specifies policy assertions related to quality of service. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion 1.1 at <a href="http://docs.oasis-open.org/ws-rx/wsrmp/200702/wsrmp-1.1-spec-os-01.pdf">http://docs.oasis-open.org/ws-rx/wsrmp/200702/wsrmp-1.1-spec-os-01.pdf</a>. See Section A.1, &quot;DefaultReliability1.1.xml (WS-Policy File)&quot;.</td>
</tr>
<tr>
<td>Reliability1.0_1.1.xml</td>
<td>Combines 1.1 and 1.0 WS Reliable Messaging policy assertions. This sample relies on smart policy selection to determine the policy assertion that is applied at runtime. See Section A.4, &quot;Reliability1.0_1.1.xml (WS-Policy.xml File)&quot;</td>
</tr>
<tr>
<td>DefaultRelibility.xml</td>
<td>Deprecated. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion Version 1.0 at <a href="http://schemas.xmlsoap.org/ws/2005/02/rm/WS-RMPolicy.pdf">http://schemas.xmlsoap.org/ws/2005/02/rm/WS-RMPolicy.pdf</a>. In this release, many of the reliable messaging policy assertions are managed through JWS annotations or configuration. Specifies typical values for the reliable messaging policy assertions, such as inactivity timeout of 10 minutes, acknowledgement interval of 200 milliseconds, and base retransmission interval of 3 seconds. See Section A.5, &quot;DefaultRelibility.xml (WS-Policy File) [Deprecated]&quot;.</td>
</tr>
<tr>
<td>LongRunningReliability.xml</td>
<td>Deprecated. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion Version 1.0 for long running processes. In this release, many of the reliable messaging policy assertions are managed through JWS annotations or configuration. Similar to the preceding default reliable messaging WS-Policy file, except that it specifies a much longer activity timeout interval (24 hours.) See Section A.6, &quot;LongRunningReliability.xml (WS-Policy File) [Deprecated]&quot;.</td>
</tr>
</tbody>
</table>

You can use one of the pre-packaged reliable messaging WS-Policy files included in WebLogic Server; these files are adequate for most use cases. You cannot modify the pre-packaged files. If the values do not suit your needs, you must create a custom WS-Policy file. The following sections describe how to create a custom WS-Policy file.

- Section 8.5.1, "Creating a Custom WS-Policy File Using WS-ReliableMessaging Policy Assertions Version 1.1"
8.5.1 Creating a Custom WS-Policy File Using WS-ReliableMessaging Policy Assertions Version 1.1

This section describes how to create a custom WS-Policy file that contains web service reliable messaging assertions that are based on WS Reliable Messaging Policy Assertion Version 1.1 at http://docs.oasis-open.org/ws-rx/wsrmp/200702/wsrmp-1.1-spec-os-01.pdf. In the current release, many of the reliable messaging policy assertions are managed through JWS annotations or configuration.

The root element of the WS-Policy file is `<Policy>` and it should include the following namespace declaration:

```xml
```

You wrap all web service reliable messaging policy assertions inside of a `<wsrmp:RMAssertion>` element. This element should include the following namespace declaration for using web service reliable messaging policy assertions:

```xml
<wsrmp:RMAssertion xmlns:wsrmp="http://docs.oasis-open.org/ws-rx/wsrmp/200702">
```

The following table lists the web service reliable messaging assertions that you can specify in the WS-Policy file. The order in which the assertions appear is important. You can specify the following assertions; the order they appear in the following list is the order in which they should appear in your WS-Policy file:

<table>
<thead>
<tr>
<th>Assertion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;wsrmp:SequenceSTR&gt;</code></td>
<td>To secure messages in a reliable sequence, the runtime will use the</td>
</tr>
<tr>
<td></td>
<td><code>wsse:SecurityTokenReference</code> that is referenced in the CreateSequence message. You can only specify one security assertion; that is, you can specify <code>wsrmp:SequenceSTR</code> or <code>wsrmp:SequenceTransportSecurity</code>, but not both.</td>
</tr>
<tr>
<td><code>&lt;wsrmp:SequenceTransportSecurity&gt;</code></td>
<td>To secure messages in a reliable sequence, the runtime will use the SSL transport session that is used to send the CreateSequence message. This assertion must be used in conjunction with the <code>sp:TransportBinding</code> assertion that requires the use of some transport-level security mechanism (for example, <code>sp:HttpsToken</code>). You can only specify one security assertion; that is, you can specify <code>wsrmp:SequenceSTR</code> or <code>wsrmp:SequenceTransportSecurity</code>, but not both.</td>
</tr>
<tr>
<td><code>&lt;wsrm:DeliveryAssurance&gt;</code></td>
<td>Delivery assurance (or quality of service) of the web service. Valid values are <code>AtMostOnce</code>, <code>AtLeastOnce</code>, <code>ExactlyOnce</code>, and <code>InOrder</code>. You can set one of the delivery assurances defined in the following table. If not set, the delivery assurance defaults to <code>ExactlyOnce</code>.</td>
</tr>
</tbody>
</table>

The following example shows a simple web service reliable messaging WS-Policy file:

```xml
<?xml version="1.0"?>
  <wsrmp:RMAssertion>
  
  </wsrmp:RMAssertion>
</wsp:Policy>
```
For more information about Reliable Messaging policy assertions in the WS-Policy file, see "Web Service Reliable Messaging Policy Assertion Reference" in WebLogic Web Services Reference for Oracle WebLogic Server.

8.5.2 Creating a Custom WS-Policy File Using WS-ReliableMessaging Policy Assertions Version 1.0 (Deprecated)

This section describes how to create a custom WS-Policy file that contains web service reliable messaging assertions that are based on WS Reliable Messaging Policy Assertion Version 1.0 at http://schemas.xmlsoap.org/ws/2005/02/rm/WS-RMPolicy.pdf.

The root element of the WS-Policy file is <Policy> and it should include the following namespace declarations for using web service reliable messaging policy assertions:

```xml
<wsp:Policy
 xmlns:wrm="http://schemas.xmlsoap.org/ws/2005/02/rm"
 xmlns:beapolicy="http://www.bea.com/wsrm/policy">
```

You wrap all web service reliable messaging policy assertions inside of a <wrm:RMAssertion> element. The assertions that use the wrm: namespace are standard ones defined by the WS-ReliableMessaging specification at http://docs.oasis-open.org/ws-rx/wrm/200702/wrm-1.1-spec-os-01.pdf. The assertions that use the beapolicy: namespace are WebLogic-specific. See "Web Service Reliable Messaging Policy Assertion Reference" in the WebLogic Web Services Reference for Oracle WebLogic Server for details.

The following table lists the web service reliable messaging assertions that you can specify in the WS-Policy file. All web service reliable messaging assertions are optional, so only set those whose default values are not adequate. The order in which the assertions appear is important. You can specify the following assertions; the order they appear in the following list is the order in which they should appear in your WS-Policy file,
The following example shows a simple web service reliable messaging WS-Policy file:

```xml
<?xml version="1.0"?>

<wsp:Policy
 xmlns:wsprm="http://schemas.xmlsoap.org/ws/2005/02/rm/policy"
 xmlns:beapolicy="http://www.bea.com/wsrm/policy"
>

<wrm:RMAssertion

<wrm:InactivityTimeout
   Milliseconds="600000" />

<wrm:BaseRetransmissionInterval
   Milliseconds="500" />

<wrm:ExponentialBackoff />

<wrm:AcknowledgementInterval
   Milliseconds="2000" />

</wrm:RMAssertion>

</wsp:Policy>
```

### Table 8–7  Web Service Reliable Messaging Assertions (Version 1.0)

<table>
<thead>
<tr>
<th>Assertion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;wrm:InactivityTimeout&gt;</code></td>
<td>Number of milliseconds, specified with the <code>Milliseconds</code> attribute, which defines an inactivity interval. After this amount of time, if the destination endpoint has not received a message from the source endpoint, the destination endpoint may consider the sequence to have terminated due to inactivity. The same is true for the source endpoint. By default, sequences never timeout.</td>
</tr>
<tr>
<td><code>&lt;wrm:BaseRetransmissionInterval&gt;</code></td>
<td>Interval, in milliseconds, that the source endpoint waits after transmitting a message and before it retransmits the message if it receives no acknowledgment for that message. Default value is set by the SAF agent on the source endpoint's WebLogic Server instance.</td>
</tr>
<tr>
<td><code>&lt;wrm:ExponentialBackoff&gt;</code></td>
<td>Specifies that the retransmission interval will be adjusted using the exponential backoff algorithm. This element has no attributes.</td>
</tr>
<tr>
<td><code>&lt;wrm:AcknowledgementInterval&gt;</code></td>
<td>Maximum interval, in milliseconds, in which the destination endpoint must transmit a stand-alone acknowledgement. The default value is set by the SAF agent on the destination endpoint's WebLogic Server instance.</td>
</tr>
<tr>
<td><code>&lt;beapolicy:Expires&gt;</code></td>
<td>Amount of time after which the reliable web service expires and does not accept any new sequence messages. The default value is to never expire. This element has a single attribute, <code>Expires</code>, whose data type is an XML Schema duration type (see <a href="http://www.w3.org/TR/2001/REC-xmlschema-2-20010502/#duration">http://www.w3.org/TR/2001/REC-xmlschema-2-20010502/#duration</a>). For example, if you want to set the expiration time to one day, use the following: <code>&lt;beapolicy:Expires Expires=&quot;P1D&quot; /&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;beapolicy:QOS&gt;</code></td>
<td>Delivery assurance level, as described in Table 8–9. The element has one attribute, <code>QOS</code>, which you set to one of the following values: <code>AtMostOnce</code>, <code>AtLeastOnce</code>, or <code>ExactlyOnce</code>. You can also include the <code>InOrder</code> string to specify that the messages be in order. The default value is <code>ExactlyOnce InOrder</code>. This element is typically not set.</td>
</tr>
</tbody>
</table>
8.3 Using Multiple Policy Alternatives

You can configure multiple policy alternatives—also referred to as smart policy alternatives—for a single web service by creating a custom policy file. At runtime, WebLogic Server selects which of the configured policies to apply. It excludes policies that are not supported or have conflicting assertions and selects the appropriate policy, based on your configured preferences, to verify incoming messages and build the response messages.

The following example provides an example of a security policy that supports both 1.1 and 1.0 WS-Reliable Messaging. Each policy alternative is enclosed in a &lt;wsp:All&gt; element.

```xml
  &lt;wsp:ExactlyOne&gt;
    &lt;wsp:All&gt;
      &lt;wsrmp10:RMAssertion xmlns:wsrmp10="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
        &lt;wsrmp10:InactivityTimeout Milliseconds="1200000"/>
        &lt;wsrmp10:BaseRetransmissionInterval Milliseconds="60000"/>
        &lt;wsrmp10:ExponentialBackoff/>
        &lt;wsrmp10:AcknowledgementInterval Milliseconds="800"/>
      </wsrmp10:RMAssertion>
    &lt;/wsp:All&gt;
    &lt;wsp:All&gt;
      &lt;wsrmp:RMAssertion xmlns:wsrmp="http://docs.oasis-open.org/ws-rx/wsrmp/200702">
        &lt;wsrmp:SequenceSTR/&gt;
        &lt;wsrmp:DeliveryAssurance&gt;
          &lt;wsp:Policy&gt;
            &lt;wsrmp:AtMostOnce/&gt;
          &lt;/wsp:Policy&gt;
        &lt;/wsrmp:DeliveryAssurance&gt;
      </wsrmp:RMAssertion>
    &lt;/wsp:All&gt;
  &lt;/wsp:ExactlyOne&gt;
&lt;/wsp:Policy&gt;
```

For more information about multiple policy alternatives, see "Smart Policy Selection" in "Configuring Message-Level Security" in Securing WebLogic Web Services for Oracle WebLogic Server.

8.6 Programming Guidelines for the Reliable JWS File

This section describes how to create the JWS file that implements the reliable web service.

The following JWS annotations are used in the JWS file that implements a reliable web service.
The following example shows a simple JWS file that implements a reliable web service; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.reliable;

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.Oneway;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.ReliabilityBuffer;
import weblogic.jws.BufferQueue;
import weblogic.jws.Policy;

/**
 * Simple reliable Web Service.
 */
@WebService(name="ReliableHelloWorldPortType",
            serviceName="ReliableHelloWorldService")
@WLHttpTransport(contextPath="ReliableHelloWorld",
                  serviceUri="ReliableHelloWorld",
                  portName="ReliableHelloWorldServicePort")
@Policy(uri="ReliableHelloWorldPolicy.xml",
        direction=Policy.Direction.both,
        attachToWsdl=true)
@BufferQueue(name="webservices.reliable.queue")
public class ReliableHelloWorldImpl {
    private static String onewaySavedInput = null;
    /**
     * A one-way helloWorld method that saves the given string for later
     * concatenation to the end of the message passed into helloWorldReturn.
     */
```
/**
 * @WebMethod()
 * @Oneway()
 * @ReliabilityBuffer(retryCount=10, retryDelay="10 seconds")
 *
 * public void helloWorld(String input) {
 *     System.out.println("Hello World " + input);
 *     onewaySavedInput = input;
 * }
 */

/**
 * This echo method concatenates the saved message from helloWorld
 * onto the end of the provided message, and returns it.
 */
@WebMethod()
@ReliabilityBuffer(retryCount=10, retryDelay="10 seconds")
public String echo(String input2) {
    System.out.println("Hello World " + input2 + onewaySavedInput);
    return input + onewaySavedInput;
}
}

In the example, the custom ReliableHelloWorldPolicy.xml policy file is attached to the web service at the class level, which means that the policy file is applied to all public operations of the web service. The policy file is applied only to the request web service message (as required by the reliable messaging feature) and it is attached to the WSDL file. For information about the pre-packaged policies available and creating a custom policy, see Section 8.5, "Creating the Web Service Reliable Messaging WS-Policy File".

The JMS queue that WebLogic Server uses internally to enable the web service reliable messaging has a JNDI name of webservices.reliable.queue, as specified by the @BufferQueue annotation.

The helloWorld() method has been marked with both the @WebMethod and @Oneway JWS annotations, which means it is a public operation called helloWorld. Because of the @Policy annotation, the operation can be invoked reliably. The web services runtime attempts to deliver reliable messages to the service a maximum of 10 times, at 10-second intervals, as described by the @ReliabilityBuffer annotation. The message may require re-delivery if, for example, the transaction is rolled back or otherwise does not commit.

The echo() method has been marked with the @WebMethod and JWS annotation, which means it is a public operation called echo. Because of the @Policy annotation, the operation can be invoked reliably. It uses the same reliability buffer configuration as the helloWorld() method.

8.6.1 Using the @Policy Annotation

Use the @Policy annotation in your JWS file to specify that the web service has a WS-Policy file attached to it that contains reliable messaging assertions. WebLogic Server delivers a set of pre-packaged WS-Policy files, as described in Appendix A, "Pre-Packaged WS-Policy Files for Reliable Messaging."

Follow the following guidelines when using the @Policy annotation for web service reliable messaging:

- Use the uri attribute to specify the build-time location of the policy file, as follows:
If you have created your own WS-Policy file, specify its location relative to the JWS file. For example:

```xml
@Policy(uri="ReliableHelloWorldPolicy.xml",
direction=Policy.Direction.both,
attachToWsdl=true)
```

In this example, the `ReliableHelloWorldPolicy.xml` file is located in the same directory as the JWS file.

To specify one of the pre-packaged WS-Policy files or a WS-Policy file that is packaged in a shared Java EE library, use the `policy:` prefix along with the name and path of the policy file. This syntax tells the `jwsc` Ant task at build-time not to look for an actual file on the file system, but rather, that the web service will retrieve the WS-Policy file from WebLogic Server at the time the service is deployed.

To specify that the policy file is published on the Web, use the `http:` prefix along with the URL, as shown in the following example:

```xml
@Policy(uri="http://someSite.com/policies/mypolicy.xml",
direction=Policy.Direction.both,
attachToWsdl=true)
```

By default, WS-Policy files are applied to both the request (inbound) and response (outbound) SOAP messages. You can change this default behavior with the `direction` attribute by setting the attribute to `Policy.Direction.inbound` or `Policy.Direction.outbound`.

You can specify whether the web service requires the operations to be invoked reliably and have the responses delivered reliably using the `wsp:optional` attribute within the policy file specified by `uri`.

If the `optional` attribute is set to `false` for outbound on any operation, then:
- The client must provide an offer sequence (`<wsrm: Offer...>` as described in the WS-ReliableMessaging specification at `http://docs.oasis-open.org/ws-rx/wsm/200702/wsmr-1.1-spec-os-01.pdf`) for use when sending reliable responses.
- Responses will be sent reliably for all operations requiring a response.

If the `optional` attribute is set to `true` for outbound on all operations, then:
- The client is not required to provide an offer sequence.
- Responses will be sent reliably if the client provides an offer sequence; otherwise, responses will be sent non-reliably.

---

**Note:** Shared Java EE libraries are useful when you want to share a WS-Policy file with multiple web services that are packaged in different Enterprise applications. As long as the WS-Policy file is located in the `META-INF/policies` or `WEB-INF/policies` directory of the shared Java EE library, you can specify the policy file in the same way as if it were packaged in the same archive at the web service. See "Creating Shared Java EE Libraries and Optional Packages” in Developing Applications for Oracle WebLogic Server for information about creating libraries and setting up your environment so the web service can locate the policy files.
- Set the attachToWsd1 attribute of the @Policy annotation to specify whether the policy file should be attached to the WSDL file that describes the public contract of the web service. Typically, you want to publicly publish the policy so that client applications know the reliable messaging capabilities of the web service. For this reason, the default value of this attribute is true.

For more information about the @Policy annotation, see “weblogic.jws.Policy” in *WebLogic Web Services Reference for Oracle WebLogic Server*.

### 8.6.2 Using the @Oneway Annotation

If you plan on invoking the reliable web service operation synchronously (or in other words, *not* using the asynchronous request-response feature), then you must annotate the implementing method with the @Oneway annotation to specify that the method is one-way. This means that the method cannot return a value, but rather, must explicitly return `void`.

Conversely, if the method is *not* annotated with the @Oneway annotation, then you must invoke it using the asynchronous request-response feature. If you are unsure how the operation is going to be invoked, consider creating two flavors of the operation: synchronous and asynchronous.

### 8.6.3 Using the @BufferQueue Annotation

Use the @BufferQueue annotation to specify the JNDI name of the JMS queue which WebLogic Server uses to store reliable messages internally. The JNDI name is the one you configured when creating a JMS queue in step 4 in Section 8.3, "Configuring the Destination WebLogic Server Instance”.

The @BufferQueue annotation is optional; if you do not specify it in your JWS file then WebLogic Server uses a queue with a JNDI name of `weblogic.wsee.DefaultQueue`. You must, however, still explicitly create a JMS queue with this JNDI name using the WebLogic Server Administration Console.

For more information about the @BufferQueue annotation, see “weblogic.jws.BufferQueue” in *WebLogic Web Services Reference for Oracle WebLogic Server*.

### 8.6.4 Using the @ReliabilityBuffer Annotation

Use the @ReliabilityBuffer annotation to specify the number of times WebLogic Server should attempt to deliver the message from the JMS queue to the web service implementation and the amount of time that the server should wait in between retries.

Use the retryCount attribute to specify the number of retries and the retryDelay attribute to specify the wait time. The format of the retryDelay attribute is a number and then one of the following strings:

- seconds
- minutes
- hours
- days
- years
For example, to specify a retry count of 20 and a retry delay of two days, use the following syntax:

```java
@ReliabilityBuffer(retryCount=20, retryDelay="2 days")
```

The retry count and delay default to 3 and 5 seconds, respectively.

For more information about the `@ReliabilityBuffer` annotation, see "weblogic.jws.ReliabilityBuffer" in WebLogic Web Services Reference for Oracle WebLogic Server.

### 8.7 Configuring Reliable Messaging for a Reliable Web Service

If necessary, you can edit the reliable message configuration options for a reliable web service that are stored in the `weblogic-webservices.xml` descriptor by updating the application deployment plan. The deployment plan associates new values with specific locations in the descriptors for your application. At deployment time, a deployment plan is merged with the descriptors in the application by applying the values in its variable assignments to the locations in the application descriptors to which the variables are linked.

The following table summarizes the reliable messaging options that can be configured for the reliable web service.

<table>
<thead>
<tr>
<th>Table 8–9 Configuration Options for Reliable Messaging</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configuration Option</strong></td>
</tr>
<tr>
<td>Customize Reliable Message Configuration</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Base Retransmission Interval</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Enable Retransmission Exponential Backoff

Flag that specifies whether the message retransmission interval will be adjusted using the exponential backoff algorithm.

This element is used in conjunction with the Base Retransmission Interval element. If a destination endpoint does not acknowledge a sequence of messages for the time interval specified by the Base Retransmission Interval, the exponential backoff algorithm is used for timing successive retransmissions by the source endpoint, should the message continue to go unacknowledged.

The exponential backoff algorithm specifies that successive retransmission intervals should increase exponentially, based on the base retransmission interval. For example, if the base retransmission interval is 2 seconds, and the exponential backoff element is set, successive retransmission intervals if messages continue to go unacknowledged are 2, 4, 8, 16, 32, and so on.

This value defaults to false, the same retransmission interval is used in successive retries; the interval does not increase exponentially.

Acknowledgement Interval

Maximum interval during which the destination endpoint must transmit a stand-alone acknowledgement.

A destination endpoint can send an acknowledgement on the return message immediately after it has received a message from a source endpoint, or it can send one separately as a stand-alone acknowledgement. If a return message is not available to send an acknowledgement, a destination endpoint may wait for up to the acknowledgement interval before sending a stand-alone acknowledgement. If there are no unacknowledged messages, the destination endpoint may choose not to send an acknowledgement.

The value specified must be a positive value and conform to the XML schema duration lexical format, \(P^nY^nM^nDT^nH^nM^nS\), where \(nY\) specifies the number of years, \(nM\) specifies the number of months, \(nD\) specifies the number of days, \(T\) is the date/time separator, \(nH\) specifies the number of hours, \(nM\) specifies the number of minutes, and \(nS\) specifies the number of seconds. This value defaults to \(P0DT0.2S\) (200 milliseconds).

Inactivity Timeout

Inactivity interval. If, during the inactivity timeout interval, an endpoint (the RM source or destination) has not received messages application or control messages, the endpoint may consider the RM sequence to have been terminated due to inactivity.

The value specified must be a positive value and conform to the XML schema duration lexical format, \(P^nY^nM^nDT^nH^nM^nS\), where \(nY\) specifies the number of years, \(nM\) specifies the number of months, \(nD\) specifies the number of days, \(T\) is the date/time separator, \(nH\) specifies the number of hours, \(nM\) specifies the number of minutes, and \(nS\) specifies the number of seconds. This value defaults to \(P0DT600S\) (600 seconds).

### Table 8–9  (Cont.) Configuration Options for Reliable Messaging

<table>
<thead>
<tr>
<th>Configuration Option</th>
<th>Description</th>

</tr>
</tbody>
</table>
You can set the reliable messaging configuration options using the WebLogic Server Administration Console or WLST, as described in the following sections.

- Section 8.7.1, "Using the Administration Console"
- Section 8.7.2, "Using WLST"

### 8.7.1 Using the Administration Console

To configure reliable messaging for the web service endpoint using the WebLogic Server Administration Console:

1. Invoke the WebLogic Server Administration Console, as described in "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server.

2. In the left navigation pane, select **Deployments**.

3. Click the name of the web service in the Deployments table.

4. Select the **Configuration** tab, then the **Ports** tab.

5. Click the name of the web service endpoint in the Ports table.

6. Select the **Reliable Message** tab.

7. Click **Customize Reliable Message Configuration** and follow the instructions to save the deployment plan, if required.

8. Set the reliable messaging properties, as required.

9. Click **Save**.

#### Table 8–9 (Cont.) Configuration Options for Reliable Messaging

<table>
<thead>
<tr>
<th>Configuration Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sequence Expiration</td>
<td>Expiration time for a sequence regardless of activity. The value specified must be a positive value and conform to the XML schema duration lexical format, <code>PnYnMnDTnHnMnS</code>, where <code>nY</code> specifies the number of years, <code>nM</code> specifies the number of months, <code>nD</code> specifies the number of days, <code>T</code> is the date/time separator, <code>nH</code> specifies the number of hours, <code>nM</code> specifies the number of minutes, and <code>nS</code> specifies the number of seconds. This value defaults to <code>P1D</code> (1 day).</td>
</tr>
<tr>
<td>Buffer Retry Count</td>
<td>Number of times to retry a reliable request. This value defaults to 3.</td>
</tr>
<tr>
<td>Buffer Retry Delay</td>
<td>Amount of time to wait before retrying a reliable request. The retry attempts are between the client's request message on the JMS queue and delivery of the message to the web service implementation. The value specified must be a positive value and conform to the XML schema duration lexical format, <code>PnYnMnDTnHnMnS</code>, where <code>nY</code> specifies the number of years, <code>nM</code> specifies the number of months, <code>nD</code> specifies the number of days, <code>T</code> is the date/time separator, <code>nH</code> specifies the number of hours, <code>nM</code> specifies the number of minutes, and <code>nS</code> specifies the number of seconds. This value defaults to <code>P0DT5S</code> (5 seconds).</td>
</tr>
</tbody>
</table>
8.7.2 Using WLST

For a complete description and example of using WLST to update an application’s deployment plan to configure reliable messaging, see "Updating the Deployment Plan" in Understanding the WebLogic Scripting Tool.

For your reference, the following table summarizes the XPath values for the WS-RM configuration options.

<table>
<thead>

</tbody>
</table>

8.8 Programming Guidelines for the JWS File That Invokes a Reliable Web Service

If you are using the WebLogic client APIs, you must invoke a reliable web service from within a web service; you cannot invoke a reliable web service from a stand-alone client application.
The following example shows a simple JWS file for a web service that invokes a reliable operation from the service described in Section 8.6, "Programming Guidelines for the Reliable JWS File".

```java
package examples.webservices.reliable;

import java.rmi.RemoteException;
import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.xml.rpc.Stub;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;
import weblogic.jws.ReliabilityErrorHandler;
import weblogic.jws.AsyncFailure;
import weblogic.jws.AsyncResponse;
import weblogic.jws.AsyncResponse;
import weblogic.jws.REliableHelloWorldPortType;
import weblogic.wsee.reliability.ReliabilityContext;
import weblogic.wsee.reliability.ReliabilityDeliveryException;
import weblogic.wsee.reliability.WsrmUtils;

@WebService(name="ReliableClientPortType",
    serviceName="ReliableClientService")
@WebLHttpTransport(contextPath="ReliableClient",
    serviceUri="ReliableClient",
    portName="ReliableClientServicePort")
public class ReliableClientImpl
{
    private static String responseMessage = null;

    @ServiceClient(
        serviceName="ReliableHelloWorldService",
        portName="ReliableHelloWorldServicePort")
    private ReliableHelloWorldPortType port;

    @WebMethod
    public void callHelloWorld(String input, String input2, String serviceUrl)
        throws RemoteException {
        ((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, serviceUrl);
        port.helloWorld(input);
        System.out.println(" Invoked the ReliableHelloWorld.helloWorld operation reliably."");
        WsrmUtils.setFinalMessage((Stub)port);
        port.echo(input2);
        System.out.println(" Invoked the ReliableHelloWorld.echo operation reliably." );
    }

    @AsyncResponse(target = "port", operation = "echo")
    public void onEchoAsyncResponse(String msg) {
```

As illustrated in the previous examples (in **bold** text), follow these guidelines when programming the JWS file that invokes a reliable web service:

- **Import the @ServiceClient and @ReliabilityErrorHandler JWS annotations:**

```java
import weblogic.jws.ServiceClient;
import weblogic.jws.ReliabilityErrorHandler;
```

- **Import the WebLogic APIs that you will use in the method that handles the error that results when the client web service does not receive an acknowledgement of message receipt from the reliable web service:**

```java
import weblogic.wsee.reliability.ReliabilityErrorContext;
import weblogic.wsee.reliability.ReliableDeliveryException;
```

- **Import the APIs used for asynchronous response and failure.**

```java
import weblogic.jws.AsyncFailure;
import weblogic.jws.AsyncResponse;
```

- **Import the JAX-RPC stub, created later by the <clientgen> child element of the jwsc Ant task, of the port type of the reliable web service you want to invoke. The stub package is specified by the packageName attribute of <clientgen>, and the name of the stub is determined by the WSDL of the invoked web service.**

```java
import examples.webservices.reliable.ReliableHelloWorldPortType;
```

- **Import the APIs used for life cycle management (to set properties and specify the final message later).**

```java
import javax.xml.rpc.Stub;
import weblogic.wsee.reliability.WsrmUtils;
```

- **In the body of the JWS file, use the @ServiceClient JWS annotation to specify the name and port of the reliable web service you want to invoke. You specify this**
annotation at the field-level on a private variable, whose data type is the JAX-RPC port type of the web service you are invoking.

```java
@ServiceClient(
    serviceName="ReliableHelloWorldService",
    portName="ReliableHelloWorldServicePort")

private ReliableHelloWorldPortType port;
```

- **Use the** `port._setProperty` **method to dynamically specify the target service endpoint address within the web service client.**

```java
((Stub)port)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, serviceUrl);
```

- **Using the stub you annotated with the** `@ServiceClient` **annotation, invoke the** `helloWorld` **reliable operation:**

```java
port.helloWorld(input);
```

Because the operation has been marked one-way, it does not return a value.

- **Create a method that handles the error when the client web service does not receive an acknowledgement from the reliable web service that the latter has received a message and annotate this method with the** `@weblogic.jws.ReliabilityErrorHandler` **annotation:**

```java
@ReliabilityErrorHandler(target="port")
public void onReliableMessageDeliveryError(ReliabilityErrorContext ctx) {
    ReliableDeliveryException fault = ctx.getFault();
    String message = null;
    if (fault != null) {
        message = ctx.getFault().getMessage();
    }
    String operation = ctx.getOperationName();
    System.out.println("Reliable operation " + operation + " may have not invoked. The error message is " + message);
}
```

This method takes `ReliabilityErrorContext` as its single parameter and returns `void`.

See "weblogic.jws.ReliabilityErrorHandler" in *WebLogic Web Services Reference for Oracle WebLogic Server* for details about programming this error-handling method.

- **Because the service is not conversational, any state kept in the port field will be lost when this method returns. In the case of reliable messaging, this state includes the ID of the reliable sequence being used to send messages. The** `setFinalMessage` **method specifies that this is the final message to be sent on this sequence. This will allow the reliable messaging subsystem to proactively clean up the reliable sequence instead of timing out.**

```java
WsrmUtils.setFinalMessage((Stub)port);
```

- **Using the stub you annotated with the** `@ServiceClient` **annotation, invoke the** `echo` **reliable operation:**

```java
port.echo(input2);
```

- **Create methods to handle the asynchronous response or failure. Use the** `@weblogic.jws.AsyncResponse` **and** `@weblogic.jws.AsyncFailure` **annotations:**

```java
@AsyncResponse(target = 'port', operation = 'echo')
public void onEchoAsyncResponse(String msg) {
    // Handle asynchronous response
}
```

```java
@AsyncFailure(target = 'port', operation = 'echo')
public void onEchoAsyncFailure(Throwable e) {
    // Handle asynchronous failure
}
```
System.out.println("ClientService: Got async response for request : " + msg);
responseMessage = msg;
}

@AsyncFailure(target = "port", operation = "echo")
public void onEchoAsyncFailure(Throwable t) {
    System.out.println("ClientService: Got async FAILURE for request : " + t);
t.printStackTrace();
}

For more information about generating asynchronous response and failure methods, see Section 7.4, "Writing the Asynchronous JWS File".

When programming the client web service:

- Do not specify any reliable messaging annotations (other than @ReliabilityErrorHandler) or use any reliable messaging assertions in the associated WS-Policy files.
- Do not specify the wsdlLocation attribute of the @ServiceClient annotation. This is because the runtime retrieval of the specified WSDL might not succeed; therefore, it is better for WebLogic Server to use a local WSDL file instead.

### 8.9 Updating the build.xml File for a Client of a Reliable Web Service

To update a build.xml file to generate the JWS file that invokes the operation of a reliable web service, add taskdef and a build-reliable-client targets similar to the following:

```
<taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />

<target name="build-reliable-client">

    <jwsc
        enableAsyncService="true"
        srcdir="src"
        destdir="${client-ear-dir}" >

    <jws file="examples/webservices/reliable/ReliableClientImpl.java">

        <clientgen
            wsdl="http://${wls.destination.host}:${wls.destination.port}/ReliableHelloWorld/ReliableHelloWorld?WSDL"
            packageName="examples.webservices.reliable"/>

    </jws>

</jwsc>

</target>
```

Use the taskdef Ant task to define the full classname of the jwsc Ant tasks.

Update the jwsc Ant task that compiles the client web service to include a clientgen child element of the <jws> element so as to generate and compile the JAX-RPC stubs for the deployed ReliableHelloWorld web service. The jwsc Ant task automatically packages them in the generated WAR file so that the client web service
can immediately access the stubs. You do this because the ReliableClientImpl JWS file imports and uses one of the generated classes.

8.10 Using Reliable Messaging With MTOM

The following example shows a simple JWS file that implements a reliable web service and uses MTOM/XOP to optimize the transmission of XML data of type xs:base64Binary in SOAP messages; see the explanation after the example for coding guidelines that correspond to the Java code in bold. This example builds on the example provided in Section 8.8, "Programming Guidelines for the JWS File That Invokes a Reliable Web Service".

```java
package examples.webservices.reliable;

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.Oneway;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.ReliabilityBuffer;
import weblogic.jws.BufferQueue;
import weblogic.jws.Policy;
import weblogic.jws.Policies;

/**
 * Simple reliable Web Service.
 */

@WebService(name="ReliableHelloWorldPortType",
            serviceName="ReliableHelloWorldService")
@WebMethod(name="ReliableHelloWorldPortType",
          implementation="com.salesforce.dcs.connector.mock.MockService")
@WLHttpTransport(contextPath="ReliableHelloWorld",
         serviceUri="ReliableHelloWorld",
         portName="ReliableHelloWorldServicePort")
@Policies({
    @Policy(uri="ReliableHelloWorldPolicy.xml",
            direction=Policy.Direction.both,
            attachToWsdl=true),
    @Policy(uri = "policy:Mtom.xml")})
@BufferQueue(name="webservices.reliable.queue")

public class ReliableHelloWorldImpl {

    @WebMethod()
    @Oneway()
    @ReliabilityBuffer(retryCount=10, retryDelay="10 seconds")

    public void helloWorld(String input) {
        System.out.println(" Hello World "+input);
    }

    @WebMethod

    public byte[] echoBinary(byte[] bytes) {
        return bytes;
    }

```
As illustrated in the previous example (in bold text), follow these guidelines when programming the JWS file that invokes a reliable web service with MTOM:

- Use the "@weblogic.jws.Policy" annotation to specify that the pre-packaged Mtom.xml file should be applied to your web service. Use the "@weblogic.jws.Policies" annotation to group multiple WS-Policy files, including the reliable messaging policy file and the MTOM policy file.

```java
@Policies({
    @Policy(uri="ReliableHelloWorldPolicy.xml",
    direction=Policy.Direction.both,
    attachToWsdl=true),
    @Policy(uri = "policy:Mtom.xml")
})
```

- Use the Java byte[] data type in your web service operations as either a return value or input parameter whenever you want the resulting SOAP message to use MTOM/XOP to send or receive the binary data.

```java
public byte[] echoBinary(byte[] bytes) {
    return bytes;
}
```

**Note:** In this release of WebLogic Server, the only supported Java data type when using MTOM/XOP is byte[]; other binary data types, such as image, are not supported.

### 8.11 Client Considerations When Redeploying a Reliable Web Service

WebLogic Server supports production redeployment, which means that you can deploy a new version of an updated reliable WebLogic web service alongside an older version of the same web service.

WebLogic Server automatically manages client connections so that only new client requests are directed to the new version. Clients already connected to the web service during the redeployment continue to use the older version of the service until they complete their work, at which point WebLogic Server automatically retires the older web service. If the client is connected to a reliable web service, its work is considered complete when the existing reliable message sequence is explicitly ended by the client or as a result of a timeout.

For additional information about production redeployment and web service clients, see "Client Considerations When Redeploying a Web Service" on page 6-17.

### 8.12 Using Reliable Messaging With a Proxy Server

Client applications that invoke reliable web services might not invoke the operation directly, but rather, use a proxy server. Reasons for using a proxy include the presence of a firewall or the deployment of the invoked web service to a cluster.

In this case, the WebLogic Server instance that hosts the invoked web service must be configured with the address and port of the proxy server. If your web service is deployed to a cluster, you must configure every server in the cluster.

This procedure describes how to create a network channel, the primary configurable WebLogic Server resource for managing network connection. Network channels enable you to provide a consistent way to access the front-end address of a cluster. For more information about network channels, see "Understanding Network Channels" in *Administering Server Environments for Oracle WebLogic Server*. 
For each server instance:

1. Create a network channel for the protocol you use to invoke the web service. You must name the network channel `weblogic-wsee-proxy-channel-XXX`, where `XXX` refers to the protocol. For example, to create a network channel for HTTPS, call it `weblogic-wsee-proxy-channel-https`.

   See "Configure custom network channels" in Oracle WebLogic Server Administration Console Online Help for general information about creating a network channel.

2. Configure the network channel, updating the **External Listen Address** and **External Listen Port** fields with the address and port of the proxy server, respectively.

3. Disable the asynchronous response service on the WebLogic Server proxy server by starting the WebLogic Server instance using the `-Dweblogic.wsee.skip.async.response=true` Java system property.

   By default, every WebLogic Server instance deploys an internal asynchronous web service that handles the asynchronous request-response feature. If you do not specify this system property, asynchronous messages will never get to the cluster, as required, because the asynchronous service on the proxy server will consume them instead.
This chapter describes how to create conversational WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of Conversational Web Services
- Creating a Conversational Web Service: Main Steps
- Programming Guidelines for the Conversational JWS File
- Programming Guidelines for the JWS File That Invokes a Conversational Web Service
- ConversationUtils Utility Class
- Updating the build.xml File for a Client of a Conversational Web Service
- Updating a Stand-Alone Java Client to Invoke a Conversational Web Service
- Example Conversational Web Service .NET Client
- Client Considerations When Redeploying a Conversational Web Service

9.1 Overview of Conversational Web Services

A web service and the client application that invokes it may communicate multiple times to complete a single task. Also, multiple client applications might communicate with the same web service at the same time. Conversations provide a straightforward way to keep track of data between calls and to ensure that the web service always responds to the correct client.

Conversations meet two challenges inherent in persisting data across multiple communications:

- Conversations uniquely identify a two-way communication between one client application and one web service so that messages are always returned to the correct client. For example, in a shopping cart application, a conversational web service keeps track of which shopping cart belongs to which customer. A conversational web service implements this by creating a unique conversation ID each time a new conversation is started with a client application.

- Conversations maintain state between calls to the web service; that is, they keep track of the data associated with a particular client application between its calls to the service. Conversations ensure that the data associated with a particular client is saved until it is no longer needed or the operation is complete. For example, in a shopping cart application, a conversational web service remembers which items are in the shopping cart while the customer continues shopping. Maintaining state
is also needed to handle failure of the computer hosting the web service in the
middle of a conversation; all state-related data is persisted to disk so that when the
computer comes up it can continue the conversation with the client application.

WebLogic Server manages this unique ID and state by creating a conversation context
each time a client application initiates a new conversation. The web service then uses
the context to correlate calls to and from the service and to persist its state-related data.

Conversations between a client application and a web service have three distinct
phases:

- **Start**—A client application initiates a conversation by invoking the start operation
  of the conversational web service. The web service in turn creates a new
  conversation context and an accompanying unique ID, and starts an internal timer
to measure the idle time and the age of the conversation.

- **Continue**—After the client application has started the conversation, it invokes one
  or more continue operations to continue the conversation. The conversational web
  service uses the ID associated with the invoke to determine which client
  application it is conversing with, what state to persist, and which idle timer to
  reset. A typical continue operation would be one that requests more information
  from the client application, requests status, and so on.

- **Finish**—A client application explicitly invokes the finish operation when it has
  finished its conversation; the web service then marks any data or resources
  associated with the conversation as deleted.

Conversations typically occur between two WebLogic web services: one is marked
conversational and defines the start, continue, and finish operations and the other web
service uses the `@ServiceClient` annotation to specify that it is a client of the
conversational web service. You can also invoke a conversational web service from a
stand-alone Java client, although there are restrictions.

As with other WebLogic web service features, you use JWS annotations to specify that
a web service is conversational.

---

**Note:** The client web service that invokes a conversational web
service is not required to also be conversational. However, if the client
is not conversational, there is a danger of multiple instances of this
client accessing the same conversational web service stub and possibly
corrupting the saved conversational state. If you believe this might
true in your case, then specify that the client web service also be
conversational. In this case you cannot use a stand-alone Java client,
because there is no way to mark it as conversational using the
WebLogic APIs.

A conversational web service on its own does not guarantee message
delivery or that the messages are delivered in order, exactly once. If
you require this kind of message delivery guarantee, you must also
specify that the web service be reliable. See Section 8.2, "Using Web
Service Reliable Messaging: Main Steps" and Chapter 11, "Using the
Asynchronous Features Together."

---

### 9.2 Creating a Conversational Web Service: Main Steps

The following procedure describes how to create a conversational web service, as well
as a client web service and stand-alone Java client application, both of which initiate
and conduct a conversation. The procedure shows how to create the JWS files that
implement the two web services from scratch. If you want to update existing JWS files, you can also use this procedure as a guide.

It is assumed that you have set up an Ant-based development environment and that you have a working build.xml file to which you can add targets for running the jwsc Ant task and deploying the generated conversational web service. It is further assumed that you have a similar setup for the WebLogic Server instance that hosts the client web service that initiates the conversation. For more information, see the following sections:

- "Examples for JAX-RPC Web Service Developers" on page 2-1
- "Developing JAX-RPC Web Services" on page 3-1
- "Programming the JWS File" on page 4-1
- "Developing JAX-RPC Web Service Clients" on page 6-1

Table 9–1  Steps to Create a Conversational Web Service

</tbody>
</table>
9.3 Programming Guidelines for the Conversational JWS File

The following example shows a simple JWS file that implements a conversational web service; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.conversation;

import java.io.Serializable;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.Conversation;
import weblogic.jws.Conversational;
import weblogic.jws.Context;
import weblogic.wsee.jws.JwsContext;
import weblogic.wsee.jws.ServiceHandle;
import javax.jws@WebService;
import javax.jws@WebMethod;
@Conversational(maxIdleTime="10 minutes",
                maxAge="1 day",
                runAsStartUser=false,
                singlePrincipal=false)
@WebService(name="ConversationalPortType",
            serviceName="ConversationalService",
            targetNamespace="http://examples.org/")
@WLHttpTransport(contextPath="conv",
                serviceUri="ConversationalService",
                portName="ConversationalServicePort")
/**
 * Conversational web service.
 */
public class ConversationalServiceImpl implements Serializable {

    @Context
    private JwsContext ctx;
    public String status = "undefined";

    @WebMethod
    @Conversation (Conversation.Phase.START)
    public String start() {
        ServiceHandle handle = ctx.getService();
        String convID = handle.getConversationID();

        status = "start";
        return "Starting conversation, with ID ' + convID + ' and status equal to " + status;
    }

    @WebMethod
    @Conversation (Conversation.Phase.CONTINUE)
    public String middle(String message) {
        status = "middle";
        return "Middle of conversation; the message is: ' + message + ' and status is " + status;
    }
}
```

---

9-4 Developing JAX-RPC Web Services for Oracle WebLogic Server 12.1.3
@WebMethod
@Conversation (Conversation.Phase.FINISH)
public String finish(String message) {
    status = 'finish';
    return 'End of conversation; the message is: " + message + " and status is " + status;
}
}

Follow these guidelines when programming the JWS file that implements a conversational web service. Code snippets of the guidelines are shown in bold in the preceding example.

- Conversational web services must implement java.io.Serializable, so you must first import the class into your JWS file:
  
  import java.io.Serializable;

- Import the conversational JWS annotations:

  import weblogic.jws.Conversation;
  import weblogic.jws.Conversational;

- If you want to access runtime information about the conversational web service, import the @Context annotation and context APIs:

  import weblogic.jws.Context;
  import weblogic.wsee.jws.JwsContext;
  import weblogic.wsee.jws.ServiceHandle;

- Use the class-level @Conversational annotation to specify that the web service is conversational. Although this annotation is optional (assuming you are specifying the @Conversation method-level annotation), it is a best practice to always use it in your JWS file to clearly specify that your web service is conversational.

  Specify any of the following optional attributes: maxIdleTime is the maximum amount of time that the web service can be idle before WebLogic Server finishes the conversation; maxAge is the maximum age of the conversation; runAsStartUser indicates whether the continue and finish phases of an existing conversation are run as the user who started the conversation; and singlePrincipal indicates whether users other than the one who started a conversation are allowed to execute the continue and finish phases of the conversation.

  @Conversational(maxIdleTime='10 minutes',
                 maxAge='1 day',
                 runAsStartUser=false,
                 singlePrincipal=false)

If a JWS file includes the @Conversational annotation, all operations of the web service are conversational. The default phase of an operation, if it does not have an explicit @Conversation annotation, is continue. However, because a conversational web service is required to include at least one start and one finish operation, you must use the method-level @Conversation annotation to specify which methods implement these operations.

9.4 Programming Guidelines for the JWS File That Invokes a Conversational Web Service

The following example shows a simple JWS file for a web service that invokes the conversational web service described in Section 9.3, "Programming Guidelines for the Conversational JWS File"; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.conversation;

```
import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;

import weblogic.wsee.conversation.ConversationUtils;

import java.rmi.RemoteException;

@WebService(name="ConversationalClientPortType",
    serviceName="ConversationalClientService",
    targetNamespace="http://examples.org/")

@WLHttpTransport(contextPath="convClient",
    serviceUri="ConversationalClient",
    portName="ConversationalClientPort")

/**
 *  client that has a conversation with the ConversationalService.
 */

public class ConversationalClientImpl {

    @ServiceClient(
        serviceName="ConversationalService",
        portName="ConversationalServicePort")

    private ConversationalPortType port;

    @WebMethod
    public void runConversation(String message) {
        try {
            // Invoke start operation
            String result = port.start();
            System.out.println("start method executed.");
            System.out.println("The message is: " + result);

             // Invoke continue operation
            result = port.middle(message);
            System.out.println("middle method executed.");
            System.out.println("The message is: " + result);

             // Invoke finish operation
            result = port.finish(message);
            System.out.println("finish method executed.");
            System.out.println("The message is: " + result);

            ConversationUtils.renewStub((Stub)port);
        }
        catch (RemoteException e) {
            e.printStackTrace();
        }
    }
}
Follow these guidelines when programming the JWS file that invokes a conversational web service; code snippets of the guidelines are shown in bold in the preceding example:

- **Import the @ServiceClient JWS annotation:**
  ```java
  import weblogic.jws.ServiceClient;
  ```

- **Optionally import the WebLogic utility class for further configuring a conversation:**
  ```java
  import weblogic.wsee.conversation.ConversationUtils;
  ```

- **Import the JAX-RPC stub of the port type of the conversational web service you want to invoke. The actual stub itself will be created later by the jwsc Ant task. The stub package is specified by the `packageName` attribute of the `<clientgen>` child element of `<jws>`, and the name of the stub is determined by the WSDL of the invoked web service.**
  ```java
  import examples.webservices.conversation.ConversationalPortType;
  ```

- **In the body of the JWS file, use the @ServiceClient JWS annotation to specify the WSDL, name, and port of the conversational web service you want to invoke. You specify this annotation at the field-level on a private variable, whose data type is the JAX-RPC port type of the web service you are invoking.**
  ```java
  @ServiceClient(
      serviceName="ConversationalService",
      portName="ConversationalServicePort")
  ```
  ```java
  private ConversationalPortType port;
  ```

- **Using the stub you annotated with the @ServiceClient annotation, invoke the start operation of the conversational web service to start the conversation. You can invoke the start method from any location in the JWS file (constructor, method, and so on):**
  ```java
  String result = port.start();
  ```

- **Optionally invoke the continue methods to continue the conversation. Be sure you use the same stub instance so that you continue the same conversation you started:**
  ```java
  result = port.middle(message);
  ```

- **Once the conversation is completed, invoke the finish operation so that the conversational web service can free up the resources it used for the current conversation:**
  ```java
  result = port.finish(message);
  ```

- **If you want to reuse the web service conversation stub to start a new conversation, you must explicitly renew the stub using the renewStub() method of the `weblogic.wsee.conversation.ConversationUtils` utility class:**
  ```java
  ConversationUtils.renewStub((Stub)port);
  ```
9.5 ConversationUtils Utility Class

WebLogic Server provides a utility class for use with the conversation feature. Use this class to perform common tasks such as getting and setting the conversation ID and setting configuration options. Some of these tasks are performed in the conversational web service, some are performed in the client that invokes the conversational web service. See Section 9.4, "Programming Guidelines for the JWS File That Invokes a Conversational Web Service" for an example of using this class.

9.6 Updating the build.xml File for a Client of a Conversational Web Service

You update a build.xml file to generate the JWS file that invokes a conversational web service by adding taskdefs and a build-clientService target that looks something like the following example. See the description after the example for details.

```xml
<taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />

<target name="build-clientService">

    <jwsc
        enableAsyncService="true"
        srcdir="src"
        destdir="${clientService-ear-dir}" >

        <jws
            file="examples/webservices/conversation/ConversationalClientImpl.java" >

            <clientgen
                wsdl="http://${wls.hostname}:${wls.port}/conv/ConversationalService?WSDL"
                packageName="examples.webservices.conversation"/>
        </jws>

    </jwsc>

</target>
```

Use the taskdef Ant task to define the full classname of the jwsc Ant tasks.

Update the jwsc Ant task that compiles the client web service to include a child element of the <jws> element so as to generate and compile the JAX-RPC stubs for the deployed ConversationalService web service. The jwsc Ant task automatically packages them in the generated WAR file so that the client web
service can immediately access the stubs. You do this because the ConversationalClientImpl JWS file imports and uses one of the generated classes.

## 9.7 Updating a Stand-Alone Java Client to Invoke a Conversational Web Service

The following example shows a simple stand-alone Java client that invokes the conversational web service described in Section 9.3, "Programming Guidelines for the Conversational JWS File". See the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.conv_standalone.client;

import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.xml.rpc.Stub;
import weblogic.wsee.jaxrpc.WLStub;

/**
 * stand-alone client that invokes and converses with ConversationlService.
 */
public class Main {
    public static void main(String[] args)
        throws ServiceException, RemoteException{
        ConversationalService service = new ConversationalService_Impl(args[0] + "?WSDL");
        ConversationalPortType port = service.getConversationalServicePort();

        // Set property on stub to specify that client is invoking a web service
        // that uses advanced features; this property is automatically set if
        // the client runs in a WebLogic Server instance.
        Stub stub = (Stub)port;
        stub._setProperty(WLStub.COMPLEX, true);

        // Invoke start operation to begin the conversation
        String result = port.start();
        System.out.println("start method executed.");
        System.out.println("The message is: " + result);

        // Invoke continue operation
        result = port.middle("middle");
        System.out.println("middle method executed.");
        System.out.println("The message is: " + result);

        // Invoke finish operation
        result = port.finish("finish");
        System.out.println("finish method executed.");
        System.out.println("The message is: " + result);
    }
}
```
Follow these guidelines when programming the stand-alone Java client that invokes a conversational web service. Code snippets of the guidelines are shown in bold in the preceding example.

- **Import the** `weblogic.wsee.jaxrpc.WLStub` **class**:

  ```java
  import weblogic.wsee.jaxrpc.WLStub;
  ```

- **Set the WLStub.Complex property** on the JAX-RPC stub of the `ConversationalService` using the `_setProperty` method:

  ```java
  Stub stub = (Stub)port;
  stub._setProperty(WLStub.COMPLEX, "true");
  ```

  This property specifies to the web services runtime that the client is going to invoke an advanced web service, in this case a conversational one. This property is automatically set when invoking a conversational web service from another WebLogic web service.

- **Invoke the start operation** of the conversational web service to start the conversation:

  ```java
  String result = port.start();
  ```

- **Optionally invoke the continue methods** to continue the conversation:

  ```java
  result = port.middle(message);
  ```

- **Once the conversation is completed**, invoke the finish operation so that the conversational web service can free up the resources it used for the current conversation:

  ```java
  result = port.finish(message);
  ```

### 9.8 Example Conversational Web Service .NET Client

This section demonstrates how to create a .NET WSE3.0 client for a WebLogic conversational web service. The example includes the following files:

- **ConversationService.java** -- JWS file that uses the `@Conversation` and `@Callback` annotations to implement a conversational web service. `ConversationService.java` can optionally communicate results to its client via a callback.

- **Service.cs** -- The C# source file of the `ConversationClient` .NET web service that acts as a client to the `ConversationService` web service.

  The sample .NET client can participate in conversations with `ConversationService`, as well as receiving results via callback.

- **build.xml** -- Ant build file that contains targets for building and deploying the Conversational web service.

These files are described in detail in the sections that follow.

#### 9.8.1 ConversationService.java File

The example `ConversationService.java` file is shown in Example 9–1. The example includes extensive comments that describe its function.
Example Conversational Web Service .NET Client

Example 9–1 ConversationService.java File

```java
package conv;

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.Oneway;
import weblogic.jws.Conversation;
import weblogic.jws.Callback;
import weblogic.jws.CallbackService;
import java.io.Serializable;

/**
 * Demonstrates use of the @Conversation annotation to manage the lifetime of the
 * service and provide data persistence and message correlation.
 * Remember that multiple clients might invoke a web service simultaneously. When
 * the web service stores data relevant to the client or calls additional services
 * in order to process a client's request, the service must be able to process
 * returned data from the external services in the context of the specific client it
 * relates to. This is all automatic when conversations are used.
 * Remember that not all clients are capable of accepting callbacks. Specifically,
 * clients operating from behind firewalls may not be able to receive asynchronous
 * callbacks. You may wish to provide a synchronous interface, like this one,
 * for such clients. If a client can accept callbacks, it must send a callback
 * endpoint reference as part of any 'start conversation' method invocation.
 * To see the behavior in the Test View, invoke startRequest and then
 * getRequestStatus several times quickly.
 */
@WebService(serviceName = "ConversationService", portName = "conversation",
            targetNamespace = "http://www.openuri.org/")
public class ConversationService implements Serializable {

    @Callback
    public CallbackInterface callback;
    private boolean useCallbacks;
    private int num;

    /**
     * Starts the conversation
     */
    @Conversation(Conversation.Phase.START)
    @WebMethod
    public void startRequest(boolean useCallbacks) {
        this.useCallbacks = useCallbacks;
    }

    @WebMethod
    @Conversation(Conversation.Phase.CONTINUE)
    public String getRequestStatus() {
```

9-12 Developing JAX-RPC Web Services for Oracle WebLogic Server 12.1.3
num++;  
if (num == 1)  
    return "This is the first time you call getRequestStatus method.";
if (num == 2 && useCallbacks) {
    callback.onResultReady("finished");
    return 'This is the second time you call getRequestStatus method, the conversation has been terminated automatically when the onResultReady callback method is invoked.';
} else
    return 'You have called getRequestStatus method " + num + " times';
}

/**
 * Used to tell Conversation.jws that the current conversation is no longer needed.
 */
@WebMethod  
@Conversation(Conversation.Phase.FINISH)
public void terminateRequest()
{

@CallbackService(serviceName = "ConversationCallbackService")
public interface CallbackInterface {

    /**
     * Callback to invoke on the client when the external service returns its result. Will only be called if the client can accept callbacks and told us where to send them.
     * @p/>
     * If this callback is used, it implicitly terminates the conversation with no action required on the part of the client.
     */
    @WebMethod
    @Oneway
    @Conversation(Conversation.Phase.FINISH)
    public void onResultReady(String result);
}

9.8.2 Service.cs File

The example Service.cs file is shown in Example 9–2.

This conversation proxy file was created using the Microsoft WSDL to Proxy Class tool WseWsdl3.exe (see http://msdn.microsoft.com/en-us/library/aa529578.aspx) and the ConversationService web service's WSDL file.

The example includes extensive comments that describe its function.

Example 9–3 build.xml File

The example build.xml file is shown in Example 9–3.

build.xml assumes that you copy the example source files to a new directory EXEMPL HOME \wl_server\examples\src\examples\webservices\conv, where EXEMPL HOME represents the directory in which the WebLogic Server code examples are configured. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in Understanding Oracle WebLogic Server.

build.xml also requires that you first set your examples environment correctly via ORACLE_HOME\user_projects\domains\wl_server>setExamplesEnv.cmd (sh and that the examples server is already started.

The example includes comments that describe the build file function and targets.

Example 9–3 build.xml File

        targets="${wls.server.name}'
        failonerror='"${failondeploy}'"/>
9.9 Client Considerations When Redeploying a Conversational Web Service

WebLogic Server supports production redeployment, which means that you can deploy a new version of an updated conversational WebLogic web service alongside an older version of the same web service.

WebLogic Server automatically manages client connections so that only new client requests are directed to the new version. Clients already connected to the web service during the redeployment continue to use the older version of the service until they complete their work, at which point WebLogic Server automatically retires the older web service. If the client is connected to a conversational web service, its work is considered complete when the existing conversation is explicitly ended by the client or because of a timeout.

For additional information about production redeployment and web service clients, see “Client Considerations When Redeploying a Web Service” on page 6-17.
This chapter describes how to create buffered WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of Buffered Web Services
- Creating a Buffered Web Service: Main Steps
- Configuring the Host WebLogic Server Instance for the Buffered Web Service
- Programming Guidelines for the Buffered JWS File
- Programming the JWS File That Invokes the Buffered Web Service
- Updating the build.xml File for a Client of the Buffered Web Service

10.1 Overview of Buffered Web Services

When a buffered operation is invoked by a client, the method operation goes on a JMS queue and WebLogic Server deals with it asynchronously. As with web service reliable messaging, if WebLogic Server goes down while the method invocation is still in the queue, it will be dealt with as soon as WebLogic Server is restarted. When a client invokes the buffered web service, the client does not wait for a response from the invoke, and the execution of the client can continue.

10.2 Creating a Buffered Web Service: Main Steps

The following procedure describes how to create a buffered web service and a client web service that invokes an operation of the buffered web service. The procedure shows how to create the JWS files that implement the two web services from scratch. If you want to update existing JWS files, use this procedure as a guide. The procedure also shows how to configure the WebLogic Server instance that hosts the buffered web service.

---

**Note:** Unless you are also using the asynchronous request-response feature, you do not need to invoke a buffered web service from another web service, you can also invoke it from a stand-alone Java application.

---

It is assumed that you have set up an Ant-based development environment and that you have a working build.xml file to which you can add targets for running the jwsc Ant task and deploying the generated buffered web service. It is further assumed that
you have a similar setup for the WebLogic Server instance that hosts the client web service that invokes the buffered web service. For more information, see the following sections:

- "Examples for JAX-RPC Web Service Developers" on page 2-1
- "Developing JAX-RPC Web Services" on page 3-1
- "Programming the JWS File" on page 4-1
- "Developing JAX-RPC Web Service Clients" on page 6-1

Table 10–1  Steps to Create a Buffered Web Service
10.3 Configuring the Host WebLogic Server Instance for the Buffered Web Service

Configuring the WebLogic Server instance on which the buffered web service is deployed involves configuring JMS resources, such as JMS servers and modules, that are used internally by the web services runtime.

You can configure these resources manually or you can use the Configuration Wizard to extend the WebLogic Server domain using a web services-specific extension template. Using the Configuration Wizard greatly simplifies the required configuration steps; for details, see “Configuring Your Domain For Web Services Features” on page 3-2.

Notes: Alternatively, you can use WLST to configure the resources. For information about using WLST to extend the domain, see "Configuring Existing Domains" in Understanding the WebLogic Scripting Tool.

A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

If you prefer to configure the resources manually, perform the following steps.
The following example shows a simple JWS file that implements a buffered web service; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.buffered;

import javax.jws.WebMethod;
import javax.jws.WebService;
import javax.jws.Oneway;
import weblogic.jws.WLHttpTransport;
import weblogic.jws.MessageBuffer;
import weblogic.jws.BufferQueue;

@WebService(name="BufferedPortType",
serviceName="BufferedService",

| 1  | Invoke the WebLogic Server Administration Console for the domain that contains the host WebLogic Server instance. | To invoke the WebLogic Server Administration Console in your browser, enter the following URL:  
http://host:port/console  
where  
- host refers to the computer on which the Administration Server is running.  
- port refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001.  
See "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server. |
| 3  | Create a JMS Server.                                                | Create a JMS Server. If a JMS server already exists, you can use it if you do not want to create a new one.  
See "Create JMS servers" in Oracle WebLogic Server Administration Console Online Help. |
| 4  | Create JMS module and define queue.                                 | Create a JMS module, and then define a JMS queue in the module. If a JMS module already exists, you can use it if you do not want to create a new one.  
Target the JMS queue to the JMS server you created in the preceding step. Be sure you specify that this JMS queue is local, typically by setting the local JNDI name. See "Create JMS system modules" and "Create queues in a system module" in Oracle WebLogic Server Administration Console Online Help.  
If you want the buffered web service to use the default web services queue, set the JNDI name of the JMS queue to weblogic.wsee.DefaultCallbackQueue. Otherwise, if you use a different JNDI name, be sure to use the @BufferQueue annotation in the JWS file to specify this JNDI name to the reliable web service. See Section 10.4, "Programming Guidelines for the Buffered JWS File".  
Clustering Considerations:  
If you are using the web service buffering feature in a cluster, you must:  
- Create a local JMS queue, rather than a distributed queue, when creating the JMS queue.  
- Explicitly target this JMS queue to each server in the cluster. |
| 4  | Tune your domain environment, as required. (Optional)               | Review “Tuning Heavily Loaded Systems to Improve Web Service Performance” in WebLogic Server Performance and Tuning. |

10.4 Programming Guidelines for the Buffered JWS File

The following example shows a simple JWS file that implements a buffered web service; see the explanation after the example for coding guidelines that correspond to the Java code in bold.
targetNamespace="http://example.org")

@WLHttpTransport(contextPath="buffered",
    serviceUri="BufferedService",
    portNames="BufferedPort")

// Annotation to specify a specific JMS queue rather than the default
@BufferQueue(name="my.jms.queue")

/**
 * Simple buffered Web Service.
 */

public class BufferedImpl {

    @WebMethod()
    @MessageBuffer(retryCount=10, retryDelay="10 seconds")
    @Oneway()
    public void sayHelloNoReturn(String message) {
        System.out.println("sayHelloNoReturn: " + message);
    }
}

Follow these guidelines when programming the JWS file that implements a buffered web service. Code snippets of the guidelines are shown in bold in the preceding example.

■ Import the JWS annotations used for buffered web services:

    import javax.jws.Oneway;
    import weblogic.jws.MessageBuffer;
    import weblogic.jws.BufferQueue;

    See the following bullets for guidelines on which JWS annotations are required.

■ Optionally use the class-level @BufferQueue JWS annotation to specify the JNDI
name of the JMS queue used internally by WebLogic Server when it processes a
buffered invoke; for example:

    @BufferQueue(name="my.jms.queue")

If you do not specify this JWS annotation, then WebLogic Server uses the default
web services JMS queue (weblogic.wsee.DefaultQueue).

You must create both the default JMS queue and any queues specified with this
annotation before you can successfully invoke a buffered operation. See
Section 10.3, "Configuring the Host WebLogic Server Instance for the Buffered Web
Service" for details.

■ Use the @MessageBuffer JWS annotation to specify the operations of the web
service that are buffered. The annotation has two optional attributes:

   - retryCount: The number of times WebLogic Server should attempt to deliver
     the message from the JMS queue to the web service implementation (default 3).
   - retryDelay: The amount of time that the server should wait in between retries
     (default 5 minutes).

For example:

    @MessageBuffer(retryCount=10, retryDelay="10 seconds")
You can use this annotation at the class-level to specify that all operations are buffered, or at the method-level to choose which operations are buffered.

- If you plan on invoking the buffered web service operation synchronously (or in other words, not using the asynchronous request-response feature), then the implementing method is required to be annotated with the @Oneway annotation to specify that the method is one-way. This means that the method cannot return a value, but rather, must explicitly return void. For example:

```java
@Oneway()
public void sayHelloNoReturn(String message) {
    // Method implementation
}
```

Conversely, if the method is not annotated with the @Oneway annotation, then you must invoke it using the asynchronous request-response feature. If you are unsure how the operation is going to be invoked, consider creating two flavors of the operation: synchronous and asynchronous.

### 10.5 Programming the JWS File That Invokes the Buffered Web Service

You can invoke a buffered web service from both a stand-alone Java application (if not using asynchronous request-response) and from another web service. Unlike other WebLogic web services asynchronous features, however, you do not use the @ServiceClient JWS annotation in the client web service, but rather, you invoke the service as you would any other. For details, see "Invoking a Web Service from Another Web Service" on page 6-9.

The following sample JWS file shows how to invoke the sayHelloNoReturn operation of the BufferedService web service:

```java
package examples.webservices.buffered;

import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;
import examples.webservices.buffered.BufferedPortType;
import examples.webservices.buffered.BufferedService_Impl;
import examples.webservices.buffered.BufferedService;

@WebService(name="BufferedClientPortType",
    serviceName="BufferedClientService",
    targetNamespace="http://examples.org")
@WLHttpTransport(contextPath="bufferedClient",
    serviceUri="BufferedClientService",
    portName="BufferedClientPort")
public class BufferedClientImpl {
    @WebMethod()
    public String callBufferedService(String input, String serviceUrl)
        throws RemoteException {
        // Method implementation
    }
}
```

10-6  Developing JAX-RPC Web Services for Oracle WebLogic Server 12.1.3
try {
    BufferedService service = new BufferedService_Impl(serviceUrl + "?WSDL");
    BufferedPortType port = service.getBufferedPort();
    // Invoke the sayHelloNoReturn() operation of BufferedService
    port.sayHelloNoReturn(input);
    return "Invoke went okay!";
} catch (ServiceException se) {
    System.out.println("ServiceExcpetion thrown");
    throw new RuntimeException(se);
}

10.6 Updating the build.xml File for a Client of the Buffered Web Service

To update a build.xml file to generate the JWS file that invokes a buffered web service operation, add taskdefs and a build-clientService targets that look something like the following example. See the description after the example for details.

```xml
<taskdef name="jwsc"
    classname="weblogic.wsee.tools.anttasks.JwscTask" />

<target name="build-clientService">
    <jwsc
        enableAsyncService="true"
        srcdir="src"
        destdir="${clientService-ear-dir}" >
        <jws file="examples/webservices/buffered/BufferedClientImpl.java">
            <clientgen
                wsdl="http://${wls.hostname}:${wls.port}/buffered/BufferedService?WSDL"
                packageName="examples.webservices.buffered"/>
        </jws>
    </jwsc>
</target>

Use the taskdef Ant task to define the full classname of the jwsc Ant tasks.

Update the jwsc Ant task that compiles the client web service to include a <clientgen> child element of the <jws> element so as to generate and compile the JAX-RPC stubs for the deployed BufferedService web service. The jwsc Ant task automatically packages them in the generated WAR file so that the client web service can immediately access the stubs. You do this because the BufferedClientImpl JWS file imports and uses one of the generated classes.
11

Using the Asynchronous Features Together

This chapter describes how to use the asynchronous features together with WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3.

This chapter includes the following sections:

■ Using the Asynchronous Features Together
■ Example of a JWS File That Implements a Reliable Conversational Web Service
■ Example of Client Web Service That Asynchronously Invokes a Reliable Conversational Web Service

11.1 Using the Asynchronous Features Together

The preceding sections describe how to use the WebLogic web service asynchronous features (web service reliable messaging, conversations, asynchronous request-response, and buffering) on their own. Typically, however, web services use the features together; see Section 11.2, "Example of a JWS File That Implements a Reliable Conversational Web Service" and Section 11.3, "Example of Client Web Service That Asynchronously Invokes a Reliable Conversational Web Service" for examples.

When used together, some restrictions described in the individual feature sections do not apply, and sometimes additional restrictions apply. The following table summarizes considerations for various feature combinations.
11.2 Example of a JWS File That Implements a Reliable Conversational Web Service

The following sample JWS file implements a web service that is both reliable and conversational:

```java
package examples.webservices.async_mega;

import java.io.Serializable;

import weblogic.jws.WLHttpTransport;
import weblogic.jws.Conversation;
import weblogic.jws.Policy;
import javax.jws.WebService;
```

---

**Table 11–1  Considerations When Using Asynchronous Features Together**

<table>
<thead>
<tr>
<th>Feature Combination</th>
<th>Consideration</th>
</tr>
</thead>
</table>
| Asynchronous request-response with web service reliable messaging or buffering | - The asynchronous response from the reliable web service is also reliable. This means that you must also configure a JMS server, module, and queue on the source WebLogic Server instance, in a similar way you configured the destination WebLogic Server instance, to handle the response.  
  
  When you create the JMS queue on the source WebLogic Server instance, you are required to specify a JNDI name of `weblogic.wsee.DefaultQueue`; you can name the queue anything you want. You must also ensure that you specify that this JMS queue is `local`, typically by setting the local JNDI name.  
  
  - The reliable or buffered operation cannot be one-way; in other words, you cannot annotate the implementing method with the `@Oneway` annotation. |
| Asynchronous request-response with web service reliable messaging | If you set a property in one of the asynchronous contexts (AsyncPreCallContext or AsyncPostCallContext), then the property must implement `java.io.Serializable`. |
| Asynchronous request-response with buffering | You must use the `@ServiceClient` JWS annotation in the client web service that invokes the buffered web service operation. |
| Conversations with web service reliable messaging | - JWS conversations are not the same as reliable sequences, and are not linked in any way. You must consider the management of reliable sequences separately from the life cycle of a conversation. For example, when using reliable messaging to send messages between a client service and a reliable and conversational service, finishing the conversation does not terminate the reliable sequence. You must explicitly cause the reliable sequence to be terminated (using `WsrmUtils.setFinalMessage()` or other acceptable method) or allows the reliable sequence to remain active until it expires when the sequence lifetime is exceeded). For more information about reliable message sequence life cycle, see Section 8.1.2, "Managing the Life Cycle of the Reliable Message Sequence".  
  
  - If you set the property `WLStub.CONVERSATIONAL_METHOD_BLOCK_TIMEOUT` on the stub of the client web service, the property is ignored because the client does not block.  
  
  - At least one method of the reliable conversational web service must not be marked with the `@Oneway` annotation. |
| Conversations with asynchronous request-response | Asynchronous responses between a client conversational web service and any other web service also participate in the conversation. For example, assume `WebServiceA` is conversational, and it invokes `WebServiceB` using asynchronous request-response. Because `WebServiceA` is conversational the asynchronous responses from `WebServiceB` also participates in the same conversation. |
import javax.jws.WebMethod;

@WebService(name="AsyncMegaPortType",
    serviceName="AsyncMegaService",
    targetNamespace="http://examples.org/")

@Policy(uri="AsyncReliableConversationPolicy.xml",
    attachToWsdl=true)

@WLHttpTransport(contextPath="asyncMega",
    serviceUri="AsyncMegaService",
    portName="AsyncMegaServicePort")

/**
 * Web Service that is both reliable and conversational.
 */

public class AsyncMegaServiceImpl implements Serializable {

@WebMethod
@Conversation (Conversation.Phase.START)
public String start() {
    return "Starting conversation";
}

@WebMethod
@Conversation (Conversation.Phase.CONTINUE)
public String middle(String message) {
    return "Middle of conversation; the message is: " + message;
}

@WebMethod
@Conversation (Conversation.Phase.FINISH)
public String finish(String message) {
    return "End of conversation; the message is: " + message;
}

}

11.3 Example of Client Web Service That Asynchronously Invokes a Reliable Conversational Web Service

The following JWS file shows how to implement a client web service that reliably invokes the various conversational methods of the web service described in Section 11.2, "Example of a JWS File That Implements a Reliable Conversational Web Service"; the client JWS file uses the asynchronous request-response feature as well.

package examples.webservices.async_mega;

import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;
import weblogic.jws.AsyncResponse;
import weblogic.jws.AsyncFailure;

import javax.jws.WebService;
import javax.jws.WebMethod;
import javax.xml.rpc.Stub;
import weblogic.wsee.async.AsyncPreCallContext;
import weblogic.wsee.async.AsyncCallContextFactory;
import weblogic.wsee.async.AsyncPostCallContext;
import weblogic.wsee.reliability.WsrmUtils;

import examples.webservices.async_mega.AsyncMegaPortType;
import examples.webservices.async_mega.AsyncMegaService;
import examples.webservices.async_mega.AsyncMegaService_Impl;

import java.rmi.RemoteException;

@WebService(name="AsyncMegaClientPortType",
    serviceName="AsyncMegaClientService",
    targetNamespace="http://examples.org/")

@WebHttpTransport(contextPath="asyncMegaClient",
    serviceUri="AsyncMegaClient",
    portName="AsyncMegaClientServicePort")

/**
 * Client Web Service that has a conversation with the AsyncMegaService
 * reliably and asynchronously.
 */

public class AsyncMegaClientImpl {

    @ServiceClient(
        serviceName="AsyncMegaService",
        portName="AsyncMegaServicePort")

    private AsyncMegaPortType port;

    @WebMethod
    public void runAsyncReliableConversation(String message) {

        AsyncPreCallContext apc = AsyncCallContextFactory.getAsyncPreCallContext();
        apc.setProperty("message", message);

        try {
            port.startAsync(apc);
            System.out.println("start method executed.");

            port.middleAsync(apc, message);
            System.out.println("middle method executed.");

            // Since this service is not conversational, any state kept in the port
            // field will be lost when this method returns. In the case of reliable
            // messaging, this state includes the ID of the reliable sequence being
            // used to send messages. The setFinalMessage method specifies
            // that this is the final message to be sent on this sequence. This
            // will allow the reliable messaging subsystem to proactively clean up
            // the reliable sequence instead of timing out.
            WsrmUtils.setFinalMessage((Stub)port);
            port.finishAsync(apc, message);
            System.out.println("finish method executed.");
        }
        catch (RemoteException e) {
            e.printStackTrace();
        }
    }
}
Example of Client Web Service That Asynchronously Invokes a Reliable Conversational Web Service

```java
@AsyncResponse(target="port", operation="start")
public void onStartAsyncResponse(AsyncPostCallContext apc, String message) {
    System.out.println("-------------------");
    System.out.println("Got message " + message);
    System.out.println("-------------------");
}

@AsyncResponse(target="port", operation="middle")
public void onMiddleAsyncResponse(AsyncPostCallContext apc, String message) {
    System.out.println("-------------------");
    System.out.println("Got message " + message);
    System.out.println("-------------------");
}

@AsyncResponse(target="port", operation="finish")
public void onFinishAsyncResponse(AsyncPostCallContext apc, String message) {
    System.out.println("-------------------");
    System.out.println("Got message " + message);
    System.out.println("-------------------");
}

@AsyncFailure(target="port", operation="start")
public void onStartAsyncFailure(AsyncPostCallContext apc, Throwable e) {
    System.out.println("-------------------");
    e.printStackTrace();
    System.out.println("-------------------");
}

@AsyncFailure(target="port", operation="middle")
public void onMiddleAsyncFailure(AsyncPostCallContext apc, Throwable e) {
    System.out.println("-------------------");
    e.printStackTrace();
    System.out.println("-------------------");
}

@AsyncFailure(target="port", operation="finish")
public void onFinishAsyncFailure(AsyncPostCallContext apc, Throwable e) {
    System.out.println("-------------------");
    e.printStackTrace();
    System.out.println("-------------------");
}
```
This chapter describes how to use callbacks with WebLogic Java API for XML-based RPC (JAX-RPC) web services to notify clients of events for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of Callbacks
- Callback Implementation Overview and Terminology
- Programming Callbacks: Main Steps
- Programming Guidelines for Target Web Service
- Programming Guidelines for the Callback Client Web Service
- Programming Guidelines for the Callback Interface
- Updating the build.xml File for the Client Web Service

12.1 Overview of Callbacks

Callbacks notify a client of your web service that some event has occurred. For example, you can notify a client when the results of that client's request are ready, or when the client's request cannot be fulfilled.

When you expose a method as a standard public operation in your JWS file (by using the `@WebMethod` annotation), the client sends a SOAP message to the web service to invoke the operation. When you add a callback to a web service, however, you define a message that the web service sends back to the client web service, notifying the client of an event that has occurred. So exposing a method as a public operation and defining a callback are completely symmetrical processes, with opposite recipients.

WebLogic Server automatically routes the SOAP message from client invoke to the target web service. In order to receive callbacks, however, the client must be operating in an environment that provides the same services. This typically means the client is a web service running on a Web server. If the client does not meet these requirements, it is likely not capable of receiving callbacks from your web service.

The protocol and message format used for callbacks is always the same as the protocol and message format used by the conversation start method that initiated the current conversation. If you attempt to override the protocol or message format of a callback, an error is thrown.

12.2 Callback Implementation Overview and Terminology

To implement callbacks, you must create or update the following three Java files:
Callback interface: Java interface file that defines the callback methods. You do not explicitly implement this file yourself; rather, the jwsc Ant task automatically generates an implementation of the interface. The implementation simply passes a message from the target web service back to the client web service. The generated web service is deployed to the same WebLogic Server that hosts the client web service.

In the example in this section, the callback interface is called CallbackInterface. The interface defines a single callback method called callbackOperation().

JWS file that implements the target web service: The target web service includes one or more standard operations that invoke a method defined in the callback interface; this method in turn sends a message back to the client web service that originally invoked the operation of the target web service.

In the example, this web service is called TargetService and it defines a single standard method called targetOperation().

JWS file that implements the client web service: The client web service invokes an operation of the target web service. This web service includes one or more methods that specify what the client should do when it receives a callback message back from the target web service via a callback method.

In the example, this web service is called CallbackClient and the method that is automatically invoked when it receives a callback is called callbackHandler(). The method that invokes TargetService in the standard way is called clientOperation().

The following graphic shows the flow of messages:

1. The clientOperation() method of the CallbackClient web service, running in one WebLogic Server instance, explicitly invokes the targetOperation() operation of the TargetService. The TargetService service might be running in a separate WebLogic Server instance.

2. The implementation of the TargetService.targetOperation() method explicitly invokes the callbackOperation() operation of the CallbackInterface, which implements the callback service. The callback service is deployed to the WebLogic Server which hosts the client web service.

3. The jwsc-generated implementation of the CallbackInterface.callbackOperation() method simply sends a message back to the CallbackClient web service. The client web service includes a method callbackHandler() that handles this message.
12.3 Programming Callbacks: Main Steps

The procedure in this section describes how to program and compile the three JWS files that are required to implement callbacks: the target web service, the client web service, and the callback interface. The procedure shows how to create the JWS files from scratch; if you want to update existing JWS files, you can also use this procedure as a guide.

It is assumed that you have set up an Ant-based development environment and that you have a working build.xml file to which you can add targets for running the jwsc Ant task and deploying the web services.

Table 12–1 Steps to Program Callbacks

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Create a new JWS file, or update an existing one, that implements the target web service.</td>
<td>Use your favorite IDE or text editor. See Section 12.4, &quot;Programming Guidelines for Target Web Service&quot;. Note: The JWS file that implements the target web service invokes one or more callback methods of the callback interface. However, the step that describes how to program the callback interface comes later in this procedure. For this reason, programmers typically program the three JWS files at the same time, rather than linearly as implied by this procedure. The steps are listed in this order for clarity only.</td>
</tr>
<tr>
<td>2</td>
<td>Update your build.xml file to include a call to the jwsc Ant task to compile the target JWS file into a web service.</td>
<td>See &quot;Running the jwsc WebLogic Web Services Ant Task&quot; on page 3-7.</td>
</tr>
<tr>
<td>3</td>
<td>Run the Ant target to build the target web service.</td>
<td>For example: prompt&gt; ant build-mainService</td>
</tr>
<tr>
<td>4</td>
<td>Deploy the target web service as usual.</td>
<td>See &quot;Deploying and Undeploying WebLogic Web Services&quot; on page 3-14.</td>
</tr>
<tr>
<td>5</td>
<td>Create a new JWS file, or update an existing one, that implements the client web service.</td>
<td>It is assumed that the client web service is deployed to a different WebLogic Server instance from the one that hosts the target web service. See Section 12.5, &quot;Programming Guidelines for the Callback Client Web Service&quot;.</td>
</tr>
<tr>
<td>6</td>
<td>Create the callback JWS interface that implements the callback web service.</td>
<td>See Section 12.6, &quot;Programming Guidelines for the Callback Interface&quot;.</td>
</tr>
<tr>
<td>7</td>
<td>Update the build.xml file that builds the client web service.</td>
<td>The jwsc Ant task that builds the client web service also implicitly generates the callback web service from the callback interface file. See Section 12.7, &quot;Updating the build.xml File for the Client Web Service&quot;.</td>
</tr>
<tr>
<td>8</td>
<td>Run the Ant target to build the client and callback web services.</td>
<td>For example: prompt&gt; ant build-clientService</td>
</tr>
<tr>
<td>9</td>
<td>Deploy the client web service as usual.</td>
<td>See &quot;Deploying and Undeploying WebLogic Web Services&quot; on page 3-14.</td>
</tr>
</tbody>
</table>

12.4 Programming Guidelines for Target Web Service

The following example shows a simple JWS file that implements the target web service; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.callback;

import weblogic.jws.WLHttpTransport;
```
import weblogic.jws.Callback;
import javax.jws.WebService;
import javax.jws.WebMethod;

@WebService(name='CallbackPortType',
            serviceName='TargetService',
            targetNamespace='http://examples.org/')
@WLHttpTransport(contextPath='callback',
                  serviceUri='TargetService',
                  portName='TargetServicePort')
/**
 * callback service
 */
public class TargetServiceImpl {

@Callback
CallbackInterface callback;

@WebMethod
public void targetOperation (String message) {
    callback.callbackOperation (message);
}
}

Follow these guidelines when programming the JWS file that implements the target web service. Code snippets of the guidelines are shown in bold in the preceding example.

- Import the required JWS annotations:

  import weblogic.jws.Callback;

- Use the @weblogic.jws.Callback JWS annotation to specify that a variable is a callback, which means that you can use the annotated variable to send callback events back to a client web service that invokes an operation of the TargetService web service. The data type of the variable is the callback interface, which in this case is called CallbackInterface.

  @Callback
  CallbackInterface callback;

- In a method that implements an operation of the TargetService, use the annotated variable to invoke one of the callback methods of the callback interface, which in this case is called callbackOperation():

  callback.callbackOperation (message);

See "JWS Annotation Reference" in WebLogic Web Services Reference for Oracle WebLogic Server for additional information about the WebLogic-specific JWS annotations discussed in this section.
12.5 Programming Guidelines for the Callback Client Web Service

The following example shows a simple JWS file for a client web service that invokes the target web service described in Section 12.4, "Programming Guidelines for Target Web Service"; see the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.callback;

import weblogic.jws.WLHttpTransport;
import weblogic.jws.ServiceClient;
import weblogic.jws.CallbackMethod;
import weblogic.jws.security.CallbackRolesAllowed;
import weblogic.jws.security.SecurityRole;

import javax.jws.WebService;
import javax.jws.WebMethod;
import examples.webservices.callback.CallbackPortType;

import java.rmi.RemoteException;

@WebService(name="CallbackClientPortType",
serviceName="CallbackClientService",
targetNamespace="http://examples.org/"
)
@WLHttpTransport(contextPath="callbackClient",
serviceUri="CallbackClient",
portName="CallbackClientPort")
public class CallbackClientImpl {

@ServiceClient(
    serviceName="TargetService",
    portName="TargetServicePort")
@CallbackRolesAllowed(@SecurityRole(role="mgr", mapToPrincipals="joe"))
private CallbackPortType port;

@WebMethod
public void clientOperation (String message) {
    try {
        port.targetOperation(message);
    }
    catch (RemoteException e) {
        e.printStackTrace();
    }
}

@CallbackMethod(target="port", operation="callbackOperation")
@CallbackRolesAllowed(@SecurityRole(role="engineer", mapToPrincipals="shackell"))
public void callbackHandler(String msg) {
    System.out.println (msg);
}
}
```
Follow these guidelines when programming the JWS file that invokes the target web service; code snippets of the guidelines are shown in bold in the preceding example:

- Import the required JWS annotations:

  ```java
  import weblogic.jws.ServiceClient;
  import weblogic.jws.CallbackMethod;
  ```

- Optionally import the security-related annotations if you want to specify the roles that are allowed to invoke the callback methods:

  ```java
  import weblogic.jws.security.CallbackRolesAllowed;
  import weblogic.jws.security.SecurityRole;
  ```

- Import the JAX-RPC stub of the port type of the target web service you want to invoke. The actual stub itself will be created later by the `jwsc` Ant task. The stub package is specified by the `packageName` attribute of the `<clientgen>` child element of `<jws>`, and the name of the stub is determined by the WSDL of the invoked web service.

  ```java
  import examples.webservices.callback.CallbackPortType;
  ```

- In the body of the JWS file, use the `@ServiceClient` JWS annotation to specify the WSDL, name, and port of the target web service you want to invoke. You specify this annotation at the field-level on a private variable, whose data type is the JAX-RPC port type of the web service you are invoking.

  ```java
  @ServiceClient(
      serviceName="TargetService",
      portName="TargetServicePort")
  @CallbackRolesAllowed(@SecurityRole(role="mgr", mapToPrincipals="joe"))
  private CallbackPortType port;
  ```

  The preceding code also shows how to use the optional `@CallbackRolesAllowed` annotation to specify the list of `@SecurityRoles` that are allowed to invoke the callback methods.

- Using the variable you annotated with the `@ServiceClient` annotation, invoke an operation of the target web service. This operation in turn will invoke a callback method of the callback interface:

  ```java
  port.targetOperation(message);
  ```

- Create a method that will handle the callback message received from the callback service. You can name this method anything you want. However, its signature should exactly match the signature of the corresponding method in the callback interface.

  ```java
  @CallbackMethod(target="port", operation="callbackOperation")
  @CallbackRolesAllowed(@SecurityRole(role="engineer", mapToPrincipals="shackell"))
  public void callbackHandler(String msg) {
      System.out.println (msg);
  }
  ```
The preceding code also shows how to use the optional \@CallbackRolesAllowed annotation to further restrict the security roles that are allowed to invoke this particular callback method.

See "JWS Annotation Reference" in WebLogic Web Services Reference for Oracle WebLogic Server for additional information about the WebLogic-specific JWS annotations discussed in this section.

12.6 Programming Guidelines for the Callback Interface

The callback interface is also a JWS file that implements a web service, except for one big difference: instead of using the standard \@javax.jws.WebService annotation to specify that it is a standard web service, you use the WebLogic-specific \@weblogic.jws.CallbackService to specify that it is a callback service. The attributes of \@CallbackService are a restricted subset of the attributes of \@WebService.

Follow these restrictions on the allowed data types and JWS annotations when programming the JWS file that implements a callback service:

- You cannot use any WebLogic-specific JWS annotations other than \@weblogic.jws.CallbackService.
- You can use all standard JWS annotations except for the following:
  - \@javax.jws.HandlerChain
  - \@javax.jws.soap.SOAPMessageHandler
  - \@javax.jws.soap.SOAPMessageHandlers
- You can use all supported data types as parameters or return values except Holder classes (user-defined data types that implement the \@javax.xml.rpc.holders.Holder interface).

The following example shows a simple callback interface file that implements a callback web service. The target web service, described in Section 12.4, "Programming Guidelines for Target Web Service", explicitly invokes a method in this interface. The jwsc-generated implementation of the callback interface then automatically sends a message back to the client web service that originally invoked the target web service; the client service is described in Section 12.5, "Programming Guidelines for the Callback Client Web Service". See the explanation after the example for coding guidelines that correspond to the Java code in bold.

```java
package examples.webservices.callback;

import weblogic.jws.CallbackService;
import javax.jws.Oneway;
import javax.jws.WebMethod;

@CallbackService
public interface CallbackInterface {

    @WebMethod
    @Oneway
    public void callbackOperation (String msg);
}
```
Follow these guidelines when programming the JWS interface file that implements the callback web service. Code snippets of the guidelines are shown in bold in the preceding example.

- Import the required JWS annotation:
  
  ```java
  import weblogic.jws.CallbackService;
  ```

- Annotate the interface declaration with the `@CallbackService` annotation to specify that the JWS file implements a callback service:
  
  ```java
  @CallbackService
  public interface CallbackInterface {
  ```

- Create a method that the target web service explicitly invokes; this is the method that automatically sends a message back to the client service that originally invoked the target web service. Because this is a Java interface file, you do not provide an implementation of this method. Rather, the WebLogic web services runtime generates an implementation of the method via the `jwsc` Ant task.
  
  ```java
  public void callbackOperation (String msg);
  ```

  **Note:** Although the example shows the callback method returning `void` and annotated with the `@Oneway` annotation, this is not a requirement.

See "JWS Annotation Reference" in WebLogic Web Services Reference for Oracle WebLogic Server for additional information about the WebLogic-specific JWS annotations discussed in this section.

### 12.7 Updating the build.xml File for the Client Web Service

When you run the `jwsc` Ant task against the JWS file that implements the client web service, the task implicitly also generates the callback web service, as described in this section.

You update a `build.xml` file to generate a client web service that invokes the target web service by adding `taskdefs` and a `build-clientService` target that looks something like the following example. See the description after the example for details.

```xml
<taskdef name="jwsc"
  classname="weblogic.wsee.tools.anttasks.JwscTask" />

<target name="build-clientService">
  <jwsc
    srcdir="src"
    destdir="${clientService-ear-dir}" >
    <jws file="examples/webservices/callback/CallbackClientImpl.java" >
      <clientgen
        wsd1="http://${wls.hostname}:${wls.port}/callback/TargetService?WSDL"
        packageName="examples.webservices.callback"
        serviceName="TargetService" />
    </jws>
  </jwsc>
</target>
```
Use the taskdef Ant task to define the full classname of the jwsc Ant tasks.

Update the jwsc Ant task that compiles the client web service to include a <clientgen> child element of the <jws> element so as to generate and compile the JAX-RPC stubs for the deployed TargetService web service. The jwsc Ant task automatically packages them in the generated WAR file so that the client web service can immediately access the stubs. You do this because the CallbackClientImpl JWS file imports and uses one of the generated classes.

Because the WSDL of the target web service includes an additional <service> element that describes the callback web service (which the target web service invokes), the <clientgen> child element of the jwsc Ant task also generates and compiles the callback web service and packages it in the same EAR file as the client web service.
This chapter describes how to use JMS transport as the connection protocol with WebLogic Java API for XML-based RPC (JAX-RPC) web service using asynchronous request-response for WebLogic Server 12.1.3.

This chapter includes the following sections:

- Overview of Using JMS Transport
- Using JMS Transport Starting From Java: Main Steps
- Using JMS Transport Starting From WSDL: Main Steps
- Configuring the Host WebLogic Server Instance for the JMS Transport Web Service
- Using the @WLJmsTransport JWS Annotation
- Using the <WLJmsTransport> Child Element of the jwsc Ant Task
- Updating the WSDL to Use JMS Transport
- Invoking a WebLogic Web Service Using JMS Transport

13.1 Overview of Using JMS Transport

Typically, client applications use HTTP/S as the connection protocol when invoking a WebLogic web service. You can, however, configure a WebLogic web service so that client applications use JMS as the transport instead.

Using JMS transport offers the following benefits: reliability, scalability, and quality of service. As with web service reliable messaging, if WebLogic Server goes down while the method invocation is still in the queue, it will be dealt with as soon as WebLogic Server is restarted. When a client invokes a web service, the client does not wait for a response from the invoke, and the execution of the client can continue. Using JMS transport does require slightly more overhead and programming complexity than HTTP/S.

You configure transports using either JWS annotations or child elements of the jwsc Ant task, as described in later sections. When a WebLogic web service is configured to use JMS as the connection transport, the endpoint address specified for the corresponding port in the generated WSDL of the web service uses jms:// in its URL rather than http://. An example of a JMS endpoint address is as follows:

```
jms://myHost:7001/transports/JMSTransport?URI=JMSTransportQueue
```

The URI=JMSTransportQueue section of the URL specifies the JMS queue that has been configured for the JMS transport feature. Although you cannot invoke the web service
using HTTP, you can view its WSDL using HTTP, which is how the clientgen is still able to generate JAX-RPC stubs for the web service.

For each transport that you specify, WebLogic Server generates an additional port in the WSDL. For this reason, if you want to give client applications a choice of transports they can use when they invoke the web service (JMS, HTTP, or HTTPS), you should explicitly add the transports using the appropriate JWS annotations or child elements of jwsc.

---

**Note:** Using JMS transport is an added-value WebLogic feature; non-WebLogic client applications, such as a .NET client, may not be able to invoke the web service using the JMS port.

### 13.2 Using JMS Transport Starting From Java: Main Steps

To use JMS transport when starting from Java, you must perform at least one of the following tasks:

- Add the @WLJmsTransport annotation to your JWS file.
- Add a <WLJmsTransport> child element to the jwsc Ant task. This setting overrides the transports defined in the JWS file.

---

**Note:** Because you might not know at the time that you are coding the JWS file which transport best suits your needs, it is often better to specify the transport at build-time using the <WLJmsTransport> child element.

The following procedure describes the complete set of steps required so that your web service can be invoked using the JMS transport when starting from Java.

---

**Note:** It is assumed that you have created a basic JWS file that implements a web service and that you want to configure the web service to be invoked using JMS. It is also assumed that you have set up an Ant-based development environment and that you have a working build.xml file that includes targets for running the jwsc Ant task and deploying the service.

<td>This step is optional. If you do not add the @WLJmsTransport annotation to your JWS file, then you must add a &lt;WLJmsTransport&gt; child element to the jwsc Ant task, as described in Step 3. See Section 13.5, &quot;Using the @WLJmsTransport JWS Annotation&quot;.</td>
</tr>
</tbody>
</table>
Using JMS Transport Starting From WSDL: Main Steps

13.3 Using JMS Transport Starting From WSDL: Main Steps

To use JMS transport when starting from WSDL, you must perform at least one of the following tasks:

- Update the WSDL to use JMS transport before running the wsdlc Ant task.
- Update the stubbed-out JWS implementation file generated by the wsdlc Ant task to add the @WLJmsTransport annotation.
- Add a <WLJmsTransport> child element to the jwsc Ant task used to build the JWS implementation file. This setting overrides the transports defined in the JWS file.

Note: Because you might not know at the time that you are coding the JWS file which transport best suits your needs, it is often better to specify the transport at build-time using the <WLJmsTransport> child element.

The following procedure describes the complete set of steps required so that your web service can be invoked using the JMS transport when starting from WSDL.

Note: It is assumed in this procedure that you have an existing WSDL file.

See Section 13.8, "Invoking a WebLogic Web Service Using JMS Transport" for information about updating your client application to invoke the web service using JMS transport.
Table 13–2 Steps to Use JMS Transport Starting From WSDL

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 | Configure the WebLogic Server domain for the required JMS components. | See Section 13.4, “Configuring the Host WebLogic Server Instance for the JMS Transport Web Service”.
| 2 | Update the WSDL to use JMS transport. (Optional) | This step is optional. If you do not update the WSDL to use JMS transport, then you must do at least one of the following:  
- Edit the stubbed out JWS file to add the @WLJmsTransport annotation to your JWS file, as described in Step 4.  
- Add a <WLJmsTransport> child element to the jwsc Ant task, as described in Step 5.  
See Section 13.7, “Updating the WSDL to Use JMS Transport”.
| 3 | Run the wsdlc Ant task against the WSDL file. | For example, if the target that calls the wsdlc Ant task is called generate-from-wsdl, then you would run:  
prompt> ant generate-from-wsdl  
See “Running the wsdlc WebLogic Web Services Ant Task” on page 3-11.
| 4 | Update the stubbed-out JWS file. | The wsdlc Ant task generates a stubbed-out JWS file. You need to add your business code to the web service so it behaves as you want. See “Updating the Stubbed-out JWS Implementation Class File Generated By wsdlc” on page 3-13.  
If you updated the WSDL to use the JMS transport in Step 2, the JWS file includes the @WLJmsTransport annotation that defines the JMS transport. If the @WLJmsTransport annotation is not included in the JWS file, you must do at least one of the following:  
- Edit the JWS file to add the @WLJmsTransport annotation to your JWS file, as described in Section 13.5, "Using the @WLJmsTransport JWS Annotation".  
- Add a <WLJmsTransport> child element to the jwsc Ant task, as described in Step 5.
| 5 | Add a <WLJmsTransport> child element to the jwsc Ant task. (Optional) | Use the <WLJmsTransport> child element to override the transports defined in the JWS file. This step is required if the JWS file does not include the @WLJmsTransport annotation, as noted in Step 4. Otherwise, this step is optional.  
See Section 13.6, “Using the <WLJmsTransport> Child Element of the jwsc Ant Task” for details.
| 6 | Run the jwsc Ant task against the JWS file to build the web service. | Specify the artifacts generated by the wsdlc Ant task as well as your updated JWS implementation file, to generate an Enterprise Application that implements the web service. See “Running the jwsc WebLogic Web Services Ant Task” on page 3-7.
| 7 | Deploy the web service to WebLogic Server. | See “Deploying and Undeploying WebLogic Web Services” on page 3-14.

See Section 13.8, "Invoking a WebLogic Web Service Using JMS Transport" for information about updating your client application to invoke the web service using JMS transport.

13.4 Configuring the Host WebLogic Server Instance for the JMS Transport Web Service

Configuring the WebLogic Server instance on which the JMS transport web service is deployed involves configuring JMS resources, such as JMS servers and modules, that are used internally by the web services runtime.
You can configure these resources manually or you can use the Configuration Wizard to extend the WebLogic Server domain using a web services-specific extension template. Using the Configuration Wizard greatly simplifies the required configuration steps; for details, see "Configuring Your Domain For Web Services Features" on page 3-2.

Notes: Alternatively, you can use WLST to configure the resources. For information about using WLST to extend the domain, see "Configuring Existing Domains" in Understanding the WebLogic Scripting Tool.

A domain that does not contain Web Services resources will still boot and operate correctly for non-web services scenarios, and any Web Services scenario that does not involve asynchronous request and response. You will, however, see INFO messages in the server log indicating that asynchronous resources have not been configured and that the asynchronous response service for web services has not been completely deployed.

If you prefer to configure the resources manually, perform the following steps.
13.5 Using the @WLJmsTransport JWS Annotation

If you know at the time that you program the JWS file that you want client applications to use JMS transport (instead of HTTP/S) to invoke the web service, you can use the @WLJmsTransport to specify the details of the invocation. Later, at build-time, you can override the invocation defined in the JWS file and add additional JMS transport specifications, by specifying the <WLJmsTransport> child element of the jwsc Ant task, as described in Section 13.6, "Using the <WLJmsTransport> Child Element of the jwsc Ant Task".

Follow these guidelines when using the @WLJmsTransport annotation:

- You can include only one @WLJmsTransport annotation in a JWS file.
- Use the queue attribute to specify the JNDI name of the JMS queue you configured earlier in the section. If you want to use the default web services queue (weblogic.wsee.DefaultQueue) then you do not have to specify the queue attribute.

---

### Table 13-3 Steps to Configure Host WebLogic Server Instance Manually for the JMS Transport Web Service

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1 | Invoke the WebLogic Server Administration Console for the domain that contains the host WebLogic Server instance. | To invoke the WebLogic Server Administration Console in your browser, enter the following URL: http://host:port/console where:  
  - host refers to the computer on which the Administration Server is running.  
  - port refers to the port number where the Administration Server is listening for connection requests. The default port number for the Administration server is 7001.  
  See "Invoking the Administration Console" in Understanding WebLogic Web Services for Oracle WebLogic Server. |
| 3 | Create a JMS Server.                                                  | Create a JMS Server. If a JMS server already exists, you can use it if you do not want to create a new one.  
See "Create JMS servers" in Oracle WebLogic Server Administration Console Online Help. |
| 4 | Create JMS module and define queue.                                  | Create a JMS module, and then define a JMS queue in the module. If a JMS module already exists, you can use it if you do not want to create a new one.  
Target the JMS queue to the JMS server you created in the preceding step. Be sure you specify that this JMS queue is local, typically by setting the local JNDI name. See "Create JMS system modules" and "Create queues in a system module" in Oracle WebLogic Server Administration Console Online Help.  
If you want the JMS transport web service to use the default web services queue, set the JNDI name of the JMS queue to weblogic.wsee.DefaultQueue. Otherwise, if you use a different JNDI name, be sure to specify the queue name when specifying the @WLJmsTransport annotation or <WLJmsTransport> child element of the jwsc Ant task.  
Clustering Considerations:  
- Create a local JMS queue, rather than a distributed queue, when creating the JMS queue.  
- Explicitly target this JMS queue to each server in the cluster. |
- Use the `connectionFactory` attribute to specify the JNDI name of the connection factory. The default value of this attribute is the default JMS connection factory for your WebLogic Server instance.

The following example shows a simple JWS file that uses the `@WLJmsTransport` annotation, with the relevant code in bold:

```java
class JMSTransportImpl {
  @WebMethod()
  public String sayHello(String message) {
    System.out.println("sayHello:" + message);
    return "Here is the message: "+ message + ";";
  }
}
```

### 13.6 Using the `<WLJmsTransport>` Child Element of the jwsc Ant Task

You can also specify the JMS transport at build-time by using the `<WLJmsTransport>` child element of the `<jws>` element of the jwsc Ant task. Reasons for specifying the transport at build-time include:

- You need to override the attribute values specified in the JWS file.
- The JWS file specifies a different transport, and at build-time you decide that JMS should be the transport.
- The JWS file does not include a `@WLXXXTransport` annotation; thus by default the HTTP transport is used, but at build-time you decide you want to clients to use the JMS transport to invoke the web service.
If you specify a transport to the `jwsc` Ant task, it takes precedence over any transport annotation in the JWS file.

The following example shows how to specify a transport to the `jwsc` Ant task:

```
<target name="build-service">

  <jwsc
    srcdir="src"
    destdir="${ear-dir}"
  >
  <jws file="examples/webservices/jmstransport/JMSTransportImpl.java">
    <WLJmsTransport
      contextPath="transports"
      serviceUri="JMSTransport"
      portName="JMSTransportServicePort"
      queue="JMSTransportQueue"
      connectionFactory="JMSTransportConnectionFactory"/>
  </jws>

</jwsc>
</target>
```

The preceding example shows how to specify the same values for the URL and JMS queue as were specified in the JWS file shown in Section 13.5, "Using the @WLJmsTransport JWS Annotation".

For more information about using the `jwsc` Ant task, see "jwsc" in WebLogic Web Services Reference for Oracle WebLogic Server.

### 13.7 Updating the WSDL to Use JMS Transport

To update the WSDL to use JMS transport, you need to add `<wsdl:binding>` and `<wsdl:service>` definitions that define JMS transport information. You can add the definitions in one of the following ways:

- **Edit the existing HTTP `<wsdl:binding>` and `<wsdl:service>` definitions.**
- **To specify multiple transport options in the WSDL, copy the existing HTTP `<wsdl:binding>` and `<wsdl:service>` definitions and edit them to use JMS transport.**

In either case, you must modify the `<wsdl:binding>` and `<wsdl:service>` definitions to use JMS transport as follows:

- **Set the transport attribute of the `<soapwsdl:binding>` child element of the `<wsdl:binding>` element to** `http://www.openuri.org/2002/04/soap/jms/`. For example:

  ```xml
  <binding name="JmsTransportServiceSoapBindingjms"
           type="tns:JmsTransportPortType">
    <soap:binding style="document"
                  transport="http://www.openuri.org/2002/04/soap/jms/*"/>
  </binding>
  ```

- **Specify a JMS-style endpoint URL for the location attribute of the `<soapwsdl:address>` child element of the `<wsdl:service>`**. For example:

  ```xml
  <s:service name="JmsTransportService">
    <s:port bindings="s1:JmsTransportServiceSoapBindingjms"
             name="JmsTransportServicePort"/>
  </s:service>
  ```
13.8 Invoking a WebLogic Web Service Using JMS Transport

You write a client application to invoke a web service using JMS transport in the same way as you write one using the HTTP transport; the only difference is that you must ensure that the JMS queue (specified by the @WLJmsTransport annotation or <WLJmsTransport> child element of the jwsc Ant task) and other JMS objects have been created. See Section 13.2, "Using JMS Transport Starting From Java: Main Steps" or Section 13.3, "Using JMS Transport Starting From WSDL: Main Steps" for more information.

Although you cannot invoke a JMS-transport-configured web service using HTTP, you can view its WSDL using HTTP, which is how the clientgen Ant task is still able to create the JAX-RPC stubs for the web service. For example, the URL for the WSDL of the web service shown in this section would be:

http://host:port/transports/JMSTransport?WSDL

However, because the endpoint address in the WSDL of the deployed web service uses jms:// instead of http://, and the address includes the qualifier ?URI=JMS_QUEUE, the clientgen Ant task automatically creates the stubs needed to use the JMS transport when invoking the web service, and your client application need not do anything different than normal. An example of a JMS endpoint address is as follows:

jms://host:port/transports/JMSTransport?URI=JMSTransportQueue

---

**Note:** If you have specified that the web service you invoke using JMS transport also runs within the context of a transaction (in other words, the JWS file includes the @weblogic.jws.Transactional annotation), you must use asynchronous request-response when invoking the service. If you do not, a deadlock will occur and the invocation will fail.

For general information about invoking a web service, see "Developing JAX-RPC Web Service Clients" on page 6-1.

13.8.1 Overriding the Default Service Address URL

When you write a client application that uses the clientgen-generated JAX-RPC stubs to invoke a web service, the default service address URL of the web service is the one specified in the <address> element of the WSDL file argument of the Service constructor.

Sometimes, however, you might need to override this address, in particular when invoking a WebLogic web service that is deployed to a cluster and you want to specify the cluster address or a list of addresses of the managed servers in the cluster. You might also want to use the t3 protocol to invoke the web service. To override this service endpoint URL when using JMS transport, use the weblogic.wsee.jaxrpc.WLStub.JMS_TRANSPORT_JNDI_URL stub property as shown in the following example:

package examples.webservices.jmstransport.client;
import weblogic.wsee.jaxrpc.WLStub;

import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.xml.rpc.Stub;

/**
 * This is a simple standalone client application that invokes the
 * the <code>sayHello</code> operation of the JMSTransport web service.
 */

public class Main {

    public static void main(String[] args)
        throws ServiceException, RemoteException {

        JMSTransportService service = new JMSTransportService_Impl(args[0] + "?WSDL");
        JMSTransportPortType port = service.getJMSTransportServicePort();

        Stub stub = (Stub) port;

        stub._setProperty(WLStub.JMS_TRANSPORT_JNDI_URL,
            "t3://shackell01.amer.com:7001");

        try {
            String result = null;
            result = port.sayHello("Hi there! ");
            System.out.println("Got JMS result: " + result);
        } catch (RemoteException e) {
            throw e;
        }
    }
}

See "WLStub" in Java API Reference for Oracle WebLogic Server for additional stub properties.

### 13.8.2 Using JMS BytesMessage Rather Than The Default TextMessage

When you use JMS transport, the web services runtime uses, by default, the javax.jms.TextMessage object to send the message. This is usually adequate for most client applications, but sometimes you might need to send binary data rather than ordinary text; in this case you must request that the web services runtime use javax.jms.BytesMessage instead. To do this, use the WLStub.JMS_TRANSPORT_MESSAGE_TYPE stub property in your client application and set it to the value WLStub.JMS_BYTESMESSAGE, as shown in the following example:

```java
stub._setProperty(WLStub.JMS_TRANSPORT_MESSAGE_TYPE,
    WLStub.JMS_BYTESMESSAGE);
```

The web services runtime sends back the response using the same message data type as the request.
See Section 13.8.1, "Overriding the Default Service Address URL" for a full example of a client application in which you can set this property. See "WLStub" in Java API Reference for Oracle WebLogic Server for additional stub properties.

13.8.3 Disabling HTTP Access to the WSDL File

As described in Section 13.8, "Invoking a WebLogic Web Service Using JMS Transport", the WSDL of the deployed web service is, by default, still accessible using HTTP. If you want to disable access to the WSDL file, in particular if your web service can be accessed outside of a firewall, then you can do one of the following:

- Use the `weblogic.jws.WSDL` annotation in your JWS file to programmatically disable access. For details, see "weblogic.jws.WSDL" in WebLogic Web Services Reference for Oracle WebLogic Server.

- Use the WebLogic Server Administration Console to disable access to the WSDL file after the web service has been deployed. In this case, the configuration information will be stored in the deployment plan rather than through the annotation.

To use the WebLogic Server Administration Console to perform this task, go to the Configuration -> General page of the deployed web service and uncheck the View Dynamic WSDL Enabled check box. After saving the configuration to the deployment plan, you must redeploy (update) the web service, or Enterprise Application which contains it, for the change to take effect.
This chapter describes how to create and use SOAP message handlers with WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3. This chapter includes the following sections:

- Overview of SOAP Message Handlers
- Adding SOAP Message Handlers to a Web Service: Main Steps
- Designing the SOAP Message Handlers and Handler Chains
- Creating the GenericHandler Class
- Configuring Handlers in the JWS File
- Creating the Handler Chain Configuration File
- Compiling and Rebuilding the Web Service
- Creating and Using Client-Side SOAP Message Handlers

14.1 Overview of SOAP Message Handlers

Some web services need access to the SOAP message, for which you can create SOAP message handlers.

A SOAP message handler provides a mechanism for intercepting the SOAP message in both the request and response of the web service. You can create handlers in both the web service itself and the client applications that invoke the web service.

A simple example of using handlers is to access information in the header part of the SOAP message. You can use the SOAP header to store web service specific information and then use handlers to manipulate it.

You can also use SOAP message handlers to improve the performance of your web service. After your web service has been deployed for a while, you might discover that many consumers invoke it with the same parameters. You could improve the performance of your web service by caching the results of popular invokes of the web service (assuming the results are static) and immediately returning these results when appropriate, without ever invoking the back-end components that implement the web service. You implement this performance improvement by using handlers to check the request SOAP message to see if it contains the popular parameters.

The following table lists the standard JWS annotations that you can use in your JWS file to specify that a web service has a handler chain configured; later sections discuss how to use the annotations in more detail. For additional information, see the web services MetaData for the Java Platform (JSR-181) specification at http://www.jcp.org/en/jsr/detail?id=181.
Overview of SOAP Message Handlers

The following table describes the main classes and interfaces of the javax.xml.rpc.handler API, some of which you use when creating the handler itself. These APIs are discussed in detail in a later section. For additional information about these APIs, see the JAX-RPC 1.1 specification at http://java.net/projects/jax-rpc/.

### Table 14–1 JWS Annotations Used To Configure SOAP Message Handler Chains

<table>
<thead>
<tr>
<th>JWS Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>javax.jws.HandlerChain</td>
<td>Associates the web service with an externally defined handler chain. Use this annotation when multiple web services need to share the same handler configuration, or if the handler chain consists of handlers for multiple transports.</td>
</tr>
<tr>
<td>javax.jws.soap.SOAPMessageHandlers</td>
<td>Specifies a list of SOAP handlers that run before and after the invocation of each web service operation. Use this annotation (rather than @HandlerChain) if embedding handler configuration information in the JWS file itself is preferred, rather than having an external configuration file. The @SOAPMessageHandler annotation is an array of @SOAPMessageHandlers. The handlers are executed in the order they are listed in this array. <strong>Note:</strong> This annotation works with JAX-RPC web services only.</td>
</tr>
<tr>
<td>javax.jws.soap.SOAPMessageHandler</td>
<td>Specifies a single SOAP message handler in the @SOAPMessageHandlers array.</td>
</tr>
</tbody>
</table>

Table 14–2 JAX-RPC Handler Interfaces and Classes

<table>
<thead>
<tr>
<th>javax.xml.rpc.handler Classes and Interfaces</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handler</td>
<td>Main interface that is implemented when creating a handler. Contains methods to handle the SOAP request, response, and faults.</td>
</tr>
<tr>
<td>GenericHandler</td>
<td>Abstract class that implements the Handler interface. User should extend this class when creating a handler, rather than implement Handler directly. The GenericHandler class is a convenience abstract class that makes writing handlers easy. This class provides default implementations of the life cycle methods init and destroy and also different handle methods. A handler developer should only override methods that it needs to specialize as part of the derived handler implementation class.</td>
</tr>
<tr>
<td>HandlerChain</td>
<td>Interface that represents a list of handlers. An implementation class for the HandlerChain interface abstracts the policy and mechanism for the invocation of the registered handlers.</td>
</tr>
<tr>
<td>HandlerRegistry</td>
<td>Interface that provides support for the programmatic configuration of handlers in a HandlerRegistry.</td>
</tr>
<tr>
<td>HandlerInfo</td>
<td>Class that contains information about the handler in a handler chain. A HandlerInfo instance is passed in the Handler.init method to initialize a Handler instance.</td>
</tr>
</tbody>
</table>
The following procedure describes the high-level steps to add SOAP message handlers to your web service.

It is assumed that you have created a basic JWS file that implements a web service and that you want to update the web service by adding SOAP message handlers and handler chains. It is also assumed that you have set up an Ant-based development environment and that you have a working `build.xml` file that includes a target for running the `jwsc` Ant task. For more information, see the following sections:

- "Examples for JAX-RPC Web Service Developers" on page 2-1
- "Developing JAX-RPC Web Services" on page 3-1
- "Programming the JWS File" on page 4-1
- "Developing JAX-RPC Web Service Clients" on page 6-1

### Table 14–3 Steps to Add SOAP Message Handlers to a Web Service

<table>
<thead>
<tr>
<th>#</th>
<th>Step</th>
<th>Description</th>
</tr>

<td>Sub-interface of the <code>MessageContext</code> interface used to get at or update the SOAP message.</td>
</tr>
<tr>
<td><code>javax.xml.soap.SOAPMessage</code></td>
<td>Object that contains the actual request or response SOAP message, including its header, body, and attachment.</td>
</tr>
</tbody>
</table>
14.3 Designing the SOAP Message Handlers and Handler Chains

When designing your SOAP message handlers and handler chains, you must decide:

- The number of handlers needed to perform all the work
- The sequence of execution

Each handler in a handler chain has one method for handling the request SOAP message and another method for handling the response SOAP message. An ordered group of handlers is referred to as a handler chain. You specify that a web service has a handler chain attached to it with one of two JWS annotations: @HandlerChain or @SOAPMessageHandler. When to use which is discussed in a later section.

When invoking a web service, WebLogic Server executes handlers as follows:

1. The handleRequest() methods of the handlers in the handler chain are all executed in the order specified by the JWS annotation. Any of these handleRequest() methods might change the SOAP message request.

2. When the handleRequest() method of the last handler in the handler chain executes, WebLogic Server invokes the back-end component that implements the web service, passing it the final SOAP message request.

3. When the back-end component has finished executing, the handleResponse() methods of the handlers in the handler chain are executed in the reverse order specified in by the JWS annotation. Any of these handleResponse() methods might change the SOAP message response.

4. When the handleResponse() method of the first handler in the handler chain executes, WebLogic Server returns the final SOAP message response to the client application that invoked the web service.

For example, assume that you are going to use the @HandlerChain JWS annotation in your JWS file to specify an external configuration file, and the configuration file defines a handler chain called SimpleChain that contains three handlers, as shown in the following sample:

```xml
  <jwshc:handler-chain>
    <jwshc:handler-chian-name>SimpleChain</jwshc:handler-chain-name>
    <jwshc:handler>
      <handler-name>handlerOne</handler-name>
      <handler-class>examples.webservices.soap_handlers.global_handler.ServerHandler1</handler-class>
    </jwshc:handler>
    <jwshc:handler>
      <handler-name>handlerTwo</handler-name>
      <handler-class>examples.webservices.soap_handlers.global_handler.ServerHandler2</handler-class>
    </jwshc:handler>
    <jwshc:handler>
      <handler-name>handlerThree</handler-name>
      <handler-class>examples.webservices.soap_handlers.global_handler.ServerHandler3</handler-class>
  </jwshc:handler-chain>
</jwshc:handler-config>
```
The following graphic shows the order in which WebLogic Server executes the handleRequest() and handleResponse() methods of each handler.

**Figure 14–1** Order of Execution of Handler Methods

Each SOAP message handler has a separate method to process the request and response SOAP message because the same type of processing typically must happen for the inbound and outbound message. For example, you might design an Encryption handler whose handleRequest() method decrypts secure data in the SOAP request and handleResponse() method encrypts the SOAP response.

You can, however, design a handler that process only the SOAP request and does no equivalent processing of the response.

You can also choose not to invoke the next handler in the handler chain and send an immediate response to the client application at any point.

### 14.4 Creating the GenericHandler Class

Your SOAP message handler class should extend the javax.rpc.xml.handler.GenericHandler abstract class, which itself implements the javax.rpc.xml.handler.Handler interface.

The GenericHandler class is a convenience abstract class that makes writing handlers easy. This class provides default implementations of the life cycle methods init() and destroy() and the various handleXXX() methods of the Handler interface. When you write your handler class, only override those methods that you need to customize as part of your Handler implementation class.

In particular, the Handler interface contains the following methods that you can implement in your handler class that extends GenericHandler:

- init()
  
  See Section 14.4.1, "Implementing the Handler.init() Method".

- destroy()
  
  See Section 14.4.2, "Implementing the Handler.destroy() Method".

- getHeaders()
  
  See Section 14.4.3, "Implementing the Handler.getHeaders() Method".

- handleRequest()
  
  See Section 14.4.4, "Implementing the Handler.handleRequest() Method".
Creating the GenericHandler Class

- `handleResponse()`
  See Section 14.4.5, "Implementing the Handler.handleResponse() Method".

- `handleFault()`
  See Section 14.4.6, "Implementing the Handler.handleFault() Method".

Sometimes you might need to directly view or update the SOAP message from within your handler, in particular when handling attachments, such as image. In this case, use the `javax.xml.soap.SOAPMessage` abstract class, which is part of the SOAP With Attachments API for Java 1.1 (SAAJ) specification at https://saaj.dev.java.net/. For details, see Section 14.4.7, "Directly Manipulating the SOAP Request and Response Message Using SAAJ".

The following example demonstrates a simple SOAP message handler that prints out the SOAP request and response messages to the WebLogic Server log file:

```java
package examples.webservices.soap_handlers.global_handler;

import javax.xml.namespace.QName;
import javax.xml.rpc.handler.HandlerInfo;
import javax.xml.rpc.handler.GenericHandler;
import javax.xml.rpc.handler.MessageContext;
import javax.xml.rpc.handler.soap.SOAPMessageContext;
import javax.xml.rpc.JAXRPCException;
import weblogic.logging.NonCatalogLogger;

/**
 * This class implements a handler in the handler chain, used to access the SOAP
 * request and response message.
 * <p>
 * This class extends the <code>javax.xml.rpc.handler.GenericHandler</code>
 * abstract class and simply prints the SOAP request and response messages to
 * the server log file before the messages are processed by the backend
 * Java class that implements the Web Service itself.
 */

public class ServerHandler1 extends GenericHandler {

    private NonCatalogLogger log;

    private HandlerInfo handlerInfo;

    /**
     * Initializes the instance of the handler. Creates a NonCatalogLogger to
     * log messages to.
     */
    public void init(HandlerInfo hi) {
        log = new NonCatalogLogger("WebService-LogHandler");
        handlerInfo = hi;
    }

    /**
     * Specifies that the SOAP request message be logged to a log file before the
     * message is sent to the Java class that implements the Web Service.
     */
    public boolean handleRequest(MessageContext context) {
```
**Creating the GenericHandler Class**

```java
SOAPMessageContext messageContext = (SOAPMessageContext) context;

System.out.println("** Request: "+messageContext.getMessage().toString());
log.info(messageContext.getMessage().toString());
return true;
}
/**
 * Specifies that the SOAP response message be logged to a log file before the
 * message is sent back to the client application that invoked the Web
 * service.
 */
public boolean handleResponse(MessageContext context) {
    SOAPMessageContext messageContext = (SOAPMessageContext) context;
    System.out.println("** Response: "+messageContext.getMessage().toString());
    log.info(messageContext.getMessage().toString());
    return true;
}
/**
 * Specifies that a message be logged to the log file if a SOAP fault is
 * thrown by the Handler instance.
 */
public boolean handleFault(MessageContext context) {
    SOAPMessageContext messageContext = (SOAPMessageContext) context;
    System.out.println("** Fault: "+messageContext.getMessage().toString());
    log.info(messageContext.getMessage().toString());
    return true;
}

public QName[] getHeaders() {
    return handlerInfo.getHeaders();
}
```
Implement the init() method if you need to process the initialization parameters or if you have other initialization tasks to perform.

Sample uses of initialization parameters are to turn debugging on or off, specify the name of a log file to which to write messages or errors, and so on.

14.4.2 Implementing the Handler.destroy() Method

The Handler.destroy() method is called to destroy an instance of a Handler object. Its signature is:

```java
public void destroy() throws JAXRPCException {}
```

Implement the destroy() method to release any resources acquired throughout the handler's life cycle.

14.4.3 Implementing the Handler.getHeaders() Method

The Handler.getHeaders() method gets the header blocks that can be processed by this Handler instance. Its signature is:

```java
public QName[] getHeaders() {}
```

14.4.4 Implementing the Handler.handleRequest() Method

The Handler.handleRequest() method is called to intercept a SOAP message request before it is processed by the back-end component. Its signature is:

```java
public boolean handleRequest(MessageContext mc)
    throws JAXRPCException, SOAPFaultException {}
```

Implement this method to perform such tasks as decrypting data in the SOAP message before it is processed by the back-end component, and so on.

The MessageContext object abstracts the message context processed by the SOAP message handler. The MessageContext properties allow the handlers in a handler chain to share processing state.

Use the SOAPMessageContext sub-interface of MessageContext to get at or update the contents of the SOAP message request. The SOAP message request itself is stored in a javax.xml.soap.SOAPMessage object. For detailed information on this object, see Section 14.4.7, "Directly Manipulating the SOAP Request and Response Message Using SAAJ".

The SOAPMessageContext class defines two methods for processing the SOAP request:

- SOAPMessageContext.getMessage() returns a javax.xml.soap.SOAPMessage object that contains the SOAP message request.
- SOAPMessageContext.setMessage(javax.xml.soap.SOAPMessage) updates the SOAP message request after you have made changes to it.

After you code all the processing of the SOAP request, code one of the following scenarios:

- Invoke the next handler on the handler request chain by returning true.

  The next handler on the request chain is specified as either the next <handler> subelement of the <handler-chain> element in the configuration file specified by the @HandlerChain annotation, or the next @SOAPMessageHandler in the array specified by the @SOAPMessageHandlers annotation. If there are no more handlers in the chain, the method either invokes the back-end component, passing it the
final SOAP message request, or invokes the `handleRequest()` method of the last handler, depending on how you have configured your web service.

- **Block processing of the handler request chain by returning `false`**.

  Blocking the handler request chain processing implies that the back-end component does not get executed for this invoke of the web service. You might want to do this if you have cached the results of certain invokes of the web service, and the current invoke is on the list.

  Although the handler request chain does not continue processing, WebLogic Server does invoke the handler response chain, starting at the current handler. For example, assume that a handler chain consists of two handlers: `handlerA` and `handlerB`, where the `handleRequest()` method of `handlerA` is invoked before that of `handlerB`. If processing is blocked in `handlerA` (and thus the `handleRequest()` method of `handlerB` is not invoked), the handler response chain starts at `handlerA` and the `handleRequest()` method of `handlerB` is not invoked either.

- **Throw the `javax.xml.rpc.soap.SOAPFaultException` to indicate a SOAP fault.**

  If the `handleRequest()` method throws a `SOAPFaultException`, WebLogic Server catches the exception, terminates further processing of the handler request chain, and invokes the `handleFault()` method of this handler.

- **Throw a `JAXRPCException` for any handler-specific runtime errors.**

  If the `handleRequest()` method throws a `JAXRPCException`, WebLogic Server catches the exception, terminates further processing of the handler request chain, logs the exception to the WebLogic Server log file, and invokes the `handleFault()` method of this handler.

### 14.4.5 Implementing the Handler`s `handleRequest()` Method

The `Handler.handleResponse()` method is called to intercept a SOAP message response after it has been processed by the back-end component, but before it is sent back to the client application that invoked the web service. Its signature is:

```java
public boolean handleResponse(MessageContext mc) throws JAXRPCException {}
```

Implement this method to perform such tasks as encrypting data in the SOAP message before it is sent back to the client application, to further process returned values, and so on.

The `MessageContext` object abstracts the message context processed by the SOAP message handler. The `MessageContext` properties allow the handlers in a handler chain to share processing state.

Use the `SOAPMessageContext` sub-interface of `MessageContext` to get at or update the contents of the SOAP message response. The SOAP message response itself is stored in a `javax.xml.soap.SOAPMessage` object. See Section 14.4.7, "Directly Manipulating the SOAP Request and Response Message Using SAAJ".

The `SOAPMessageContext` class defines two methods for processing the SOAP response:

- `SOAPMessageContext.getMessage()`: returns a `javax.xml.soap.SOAPMessage` object that contains the SOAP message response.

- `SOAPMessageContext.setMessage(javax.xml.soap.SOAPMessage)`: updates the SOAP message response after you have made changes to it.
After you code all the processing of the SOAP response, code one of the following scenarios:

- **Invoke the next handler on the handler response chain by returning `true`.**
  
  The next response on the handler chain is specified as either the preceding `<handler>` subelement of the `<handler-chain>` element in the configuration file specified by the `@HandlerChain` annotation, or the preceding `@SOAPMessageHandler` in the array specified by the `@SOAPMessageHandlers` annotation. (Remember that responses on the handler chain execute in the *reverse* order that they are specified in the JWS file. See Section 14.3, "Designing the SOAP Message Handlers and Handler Chains" for more information.)

  If there are no more handlers in the chain, the method sends the final SOAP message response to the client application that invoked the web service.

- **Block processing of the handler response chain by returning `false`.**

  Blocking the handler response chain processing implies that the remaining handlers on the response chain do not get executed for this invoke of the web service and the current SOAP message is sent back to the client application.

- **Throw a `JAXRPCException` for any handler specific runtime errors.**

  If the `handleRequest()` method throws a `JAXRPCException`, WebLogic Server catches the exception, terminates further processing of the handler request chain, logs the exception to the WebLogic Server logfile, and invokes the `handleFault()` method of this handler.

### 14.4.6 Implementing the Handler.handleFault() Method

The `Handler.handleFault()` method processes the SOAP faults based on the SOAP message processing model. Its signature is:

```java
public boolean handleFault(MessageContext mc) throws JAXRPCException {}
```

Implement this method to handle processing of any SOAP faults generated by the `handleRequest()` and `handleRequest()` methods, as well as faults generated by the back-end component.

The `MessageContext` object abstracts the message context processed by the SOAP message handler. The `MessageContext` properties allow the handlers in a handler chain to share processing state.

Use the `SOAPMessageContext` sub-interface of `MessageContext` to get at or update the contents of the SOAP message. The SOAP message itself is stored in a `javax.xml.soap.SOAPMessage` object. See Section 14.4.7, "Directly Manipulating the SOAP Request and Response Message Using SAAJ".

The `SOAPMessageContext` class defines the following two methods for processing the SOAP message:

- `SOAPMessageContext.getMessage()`: returns a `javax.xml.soap.SOAPMessage` object that contains the SOAP message.
- `SOAPMessageContext.setMessage(javax.xml.soap.SOAPMessage)`: updates the SOAP message after you have made changes to it.

After you code all the processing of the SOAP fault, do one of the following:

- **Invoke the `handleFault()` method on the next handler in the handler chain by returning `true`.**
14.4.7 Directly Manipulating the SOAP Request and Response Message Using SAAJ

The javax.xml.soap.SOAPMessage abstract class is part of the SOAP With Attachments API for Java 1.1 (SAAJ) specification (see https://saaj.dev.java.net/). You use the class to manipulate request and response SOAP messages when creating SOAP message handlers. This section describes the basic structure of a SOAPMessage object and some of the methods you can use to view and update a SOAP message.

A SOAPMessage object consists of a SOAPPart object (which contains the actual SOAP XML document) and zero or more attachments.

Refer to the SAAJ Javadocs for the full description of the SOAPMessage class.

14.4.7.1 The SOAPPart Object

The SOAPPart object contains the XML SOAP document inside of a SOAPEnvelope object. You use this object to get the actual SOAP headers and body.

The following sample Java code shows how to retrieve the SOAP message from a MessageContext object, provided by the Handler class, and get at its parts:

```java
SOAPMessage soapMessage = messageContext.getMessage();
SOAPPart soapPart = soapMessage.getSOAPPart();
SOAPEnvelope soapEnvelope = soapPart.getEnvelope();
SOAPBody soapBody = soapEnvelope.getBody();
SOAPHeader soapHeader = soapEnvelope.getHeader();
```

14.4.7.2 The AttachmentPart Object

The javax.xml.soap.AttachmentPart object contains the optional attachments to the SOAP message. Unlike the rest of a SOAP message, an attachment is not required to be in XML format and can therefore be anything from simple text to an image file.

**Note:** If you are going to access a java.awt.Image attachment from your SOAP message handler, see Section 14.4.7.3, "Manipulating Image Attachments in a SOAP Message Handler" for important information.

Use the following methods of the SOAPMessage class to manipulate the attachments:

- `countAttachments()`: returns the number of attachments in this SOAP message.
- `getAttachments()`: retrieves all the attachments (as AttachmentPart objects) into an Iterator object.
- `createAttachmentPart()`: create an AttachmentPart object from another type of Object.
- `addAttachmentPart()`: adds an AttachmentPart object, after it has been created, to the SOAPMessage.

14.4.7.3 Manipulating Image Attachments in a SOAP Message Handler

It is assumed in this section that you are creating a SOAP message handler that accesses a java.awt.Image attachment and that the Image has been sent from a client application that uses the client JAX-RPC stubs generated by the clientgen Ant task.
In the client code generated by the `clientgen` Ant task, a `java.awt.Image` attachment is sent to the invoked WebLogic web service with a MIME type of `text/xml` rather than `image/gif`, and the image is serialized into a stream of integers that represents the image. In particular, the client code serializes the image using the following format:

- int width
- int height
- int[] pixels

This means that, in your SOAP message handler that manipulates the received Image attachment, you must deserialize this stream of data to then re-create the original image.

### 14.5 Configuring Handlers in the JWS File

There are two standard annotations you can use in your JWS file to configure a handler chain for a web service: `@javax.jws.HandlerChain` and `@javax.jws.soap.SOAPMessageHandlers`.

#### 14.5.1 @javax.jws.HandlerChain

When you use the `@javax.jws.HandlerChain` annotation (also called `@HandlerChain` in this chapter for simplicity) you use the `file` attribute to specify an external file that contains the configuration of the handler chain you want to associate with the web service. The configuration includes the list of handlers in the chain, the order in which they execute, the initialization parameters, and so on.

Use the `@HandlerChain` annotation, rather than the `@SOAPMessageHandlers` annotation, in your JWS file if one or more of the following conditions apply:

- You want multiple web services to share the same configuration.
- Your handler chain includes handlers for multiple transports.
- You want to be able to change the handler chain configuration for a web service without recompiling the JWS file that implements it.

The following JWS file shows an example of using the `@HandlerChain` annotation; the relevant Java code is shown in bold:

```java
package examples.webservices.soap_handlers.global_handler;

import java.io.Serializable;
import javax.jws.HandlerChain;
import javax.jws.WebService;
import javax.jws.WebMethod;
import javax.jws.soap.SOAPBinding;
import weblogic.jws.WLHttpTransport;

@WebService(serviceName="HandlerChainService",
   name="HandlerChainPortType")

// Standard JWS annotation that specifies that the handler chain called
// "SimpleChain", configured in the HandlerConfig.xml file, should fire
// each time an operation of the Web Service is invoked.
```
@HandlerChain(file="HandlerConfig.xml", name="SimpleChain")

@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
use=SOAPBinding.Use.LITERAL,
parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)

@WLHttpTransport(contextPath="HandlerChain", serviceUri="HandlerChain",
portName="HandlerChainServicePort")

/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHello. The Web Service also
 * has a handler chain associated with it, as specified by the
 * @HandlerChain annotation.
 */

public class HandlerChainImpl {

    public String sayHello(String input) {
        weblogic.utils.Debug.say( "in backend component. input:" +input );
        return "'" + input + "' to you too!";
    }
}

Before you use the @HandlerChain annotation, you must import it into your JWS file,
  as shown in the preceding example.

Use the file attribute of the @HandlerChain annotation to specify the name of the
external file that contains configuration information for the handler chain. The value of
this attribute is a URL, which may be relative or absolute. Relative URLs are relative to
the location of the JWS file at the time you run the jwsc Ant task to compile the file.

Use the name attribute to specify the name of the handler chain in the configuration
file that you want to associate with the web service. The value of this attribute
  corresponds to the name attribute of the <handler-chain> element in the configuration
file.

---

**Note:** It is an error to specify more than one @HandlerChain
  annotation in a single JWS file. It is also an error to combine the
  @HandlerChain annotation with the @SOAPMessageHandlers
  annotation.

---

For details about creating the external configuration file, see Section 14.6, "Creating the
Handler Chain Configuration File".

For additional detailed information about the standard JWS annotations discussed in
this section, see the web services Metadata for the Java Platform specification at

14.5.2 @javax.jws.soap.SOAPMessageHandlers

---

**Note:** This annotation has been deprecated as of the web services
Metadata for the Java Platform specification (JSR-181) at

---
When you use the `@javax.jws.soap.SOAPMessageHandlers` (also called `@SOAPMessageHandlers` in this section for simplicity) annotation, you specify, within the JWS file itself, an array of SOAP message handlers (specified with the `@SOAPMessageHandler` annotation) that execute before and after the operations of a web service. The `@SOAPMessageHandler` annotation includes attributes to specify the class name of the handler, the initialization parameters, list of SOAP headers processed by the handler, and so on. Because you specify the list of handlers within the JWS file itself, the configuration of the handler chain is embedded within the web service.

Use the `@SOAPMessageHandlers` annotation if one or more of the following conditions apply:

- You prefer to embed the configuration of the handler chain inside the web service itself, rather than specify the configuration in an external file.
- Your handler chain includes only SOAP handlers and none for any other transport.
- You prefer to recompile the JWS file each time you change the handler chain configuration.

The following JWS file shows a simple example of using the `@SOAPMessageHandlers` annotation; the relevant Java code is shown in bold:

```java
package examples.webservices.soap_handlers.simple;

import java.io.Serializable;
import javax.jws.soap.SOAPMessageHandlers;
import javax.jws.soap.SOAPMessageHandler;
import javax.jws.soap.SOAPBinding;
import javax.jws.WebService;
import javax.jws.WebMethod;
import weblogic.jws.WLHttpTransport;

@WebService(name="SimpleChainPortType",
    serviceName="SimpleChainService")
// Standard JWS annotation that specifies a list of SOAP message handlers
// that execute before and after an invocation of all operations in the
// Web Service.
@SOAPMessageHandlers ( {
    @SOAPMessageHandler (
        className="examples.webservices.soap_handlers.simple.ServerHandler1"),
    @SOAPMessageHandler (
        className="examples.webservices.soap_handlers.simple.ServerHandler2")
} )
@SOAPBinding(style=SOAPBinding.Style.DOCUMENT,
    use=SOAPBinding.Use.LITERAL,
    parameterStyle=SOAPBinding.ParameterStyle.WRAPPED)
@WLHttpTransport(contextPath="SimpleChain", serviceUri="SimpleChain",
    portName="SimpleChainServicePort")

/**
 * This JWS file forms the basis of simple Java-class implemented WebLogic
 * Web Service with a single operation: sayHello. The Web Service also
 * has a handler chain associated with it, as specified by the
 */
```
Before you use the @SOAPMessageHandlers and @SOAPMessageHandler annotations, you must import them into your JWS file, as shown in the preceding example. Note that these annotations are in the javax.jws.soap package.

The order in which you list the handlers (using the @SOAPMessageHandler annotation) in the @SOAPMessageHandlers array specifies the order in which the handlers execute: in forward order before the operation, and in reverse order after the operation. The preceding example configures two handlers in the handler chain, whose class names are examples.webservices.soap_handlers.simple.ServerHandler1 and examples.webservices.soap_handlers.simple.ServerHandler2.

Use the initParams attribute of @SOAPMessageHandler to specify an array of initialization parameters expected by a particular handler. Use the @InitParam standard JWS annotation to specify the name/value pairs, as shown in the following example:

```java
@SOAPMessageHandler(
    className = "examples.webservices.soap_handlers.simple.ServerHandler1",
    initParams = { @InitParam(name="logCategory", value="MyService")})
```

The @SOAPMessageHandler annotation also includes the roles attribute for listing the SOAP roles implemented by the handler, and the headers attribute for listing the SOAP headers processed by the handler.

---

**Note:** It is an error to combine the @SOAPMessageHandlers annotation with the @HandlerChain annotation.

---

### 14.6 Creating the Handler Chain Configuration File

If you decide to use the @HandlerChain annotation in your JWS file to associate a handler chain with a web service, you must create an external configuration file that specifies the list of handlers in the handler chain, the order in which they execute, the initialization parameters, and so on.

Because this file is external to the JWS file, you can configure multiple web services to use this single configuration file to standardize the handler configuration file for all web services in your enterprise. Additionally, you can change the configuration of the handler chains without needing to recompile all your web services. Finally, if you include handlers in your handler chain that use a non-SOAP transport, then you are
required to use the @HandlerChain annotation rather than the @SOAPMessageHandler annotation.

The configuration file uses XML to list one or more handler chains, as shown in the following simple example:

```xml
xmlns:soap1="http://HandlerInfo.org/Server1"
xmlns:soap2="http://HandlerInfo.org/Server2"
xmns="http://java.sun.com/xml/ns/j2ee">
  <jwshc:handler-chain>
    <jwshc:handler-chain-name>SimpleChain</jwshc:handler-chain-name>
    <jwshc:handler>
      <handler-name>handler1</handler-name>
      <handler-class>examples.webservices.soap_handlers.global_handler.ServerHandler1</handler-class>
    </jwshc:handler>
    <jwshc:handler>
      <handler-name>handler2</handler-name>
      <handler-class>examples.webservices.soap_handlers.global_handler.ServerHandler2</handler-class>
    </jwshc:handler>
  </jwshc:handler-chain>
</jwshc:handler-config>
```

In the example, the handler chain called SimpleChain contains two handlers: handler1 and handler2, implemented with the class names specified with the <handler-class> element. The two handlers execute in forward order before the relevant web service operation executes, and in reverse order after the operation executes.

Use the <init-param>, <soap-role>, and <soap-header> child elements of the <handler> element to specify the handler initialization parameters, SOAP roles implemented by the handler, and SOAP headers processed by the handler, respectively.

For the XML Schema that defines the external configuration file, additional information about creating it, and additional examples, see the web services Metadata for the Java Platform specification at http://www.jcp.org/en/jsr/detail?id=181.

### 14.7 Compiling and Rebuilding the Web Service

It is assumed in this section that you have a working build.xml Ant file that compiles and builds your web service, and you want to update the build file to include handler chain. See "Developing JAX-RPC Web Services" on page 3-1 for information on creating this build.xml file.

Follow these guidelines to update your development environment to include message handler compilation and building:

- After you have updated the JWS file with either the @HandlerChain or @SOAPMessageHandlers annotation, you must rerun the jwsc Ant task to recompile the JWS file and generate a new web service. This is true anytime you make a change to an annotation in the JWS file.

If you used the @HandlerChain annotation in your JWS file, reran the jwsc Ant task to regenerate the web service, and subsequently changed only the external configuration file, you do not need to rerun jwsc for the second change to take affect.
Creating and Using Client-Side SOAP Message Handlers

The `jwsc` Ant task compiles SOAP message handler Java files into handler classes (and then packages them into the generated application) if all the following conditions are true:

- The handler classes are referenced in the `@HandlerChain` or `@SOAPMessageHandler(s)` annotations of the JWS file.
- The Java files are located in the directory specified by the `sourcepath` attribute.
- The classes are not currently in your CLASSPATH.

If you want to compile the handler classes yourself, rather than let `jwsc` compile them automatically, ensure that the compiled classes are in your CLASSPATH before you run the `jwsc` Ant task.

You deploy and invoke a web service that has a handler chain associated with it in the same way you deploy and invoke one that has no handler chain. The only difference is that when you invoke any operation of the web service, the WebLogic web services runtime executes the handlers in the handler chain both before and after the operation invoke.

14.8 Creating and Using Client-Side SOAP Message Handlers

The preceding sections describe how to create server-side SOAP message handlers that execute as part of the web service running on WebLogic Server. You can also create client-side handlers that execute as part of the client application that invokes a web service operation. In the case of a client-side handler, the handler executes twice:

- Directly before the client application sends the SOAP request to the web service
- Directly after the client application receives the SOAP response from the web service

You can configure client-side SOAP message handlers for both stand-alone clients and clients that run inside of WebLogic Server.

You create the actual Java client-side handler in the same way you create a server-side handler: write a Java class that extends the `javax.xml.rpc.handler.GenericHandler` abstract class. In many cases you can use the exact same handler class on both the web service running on WebLogic Server and the client applications that invoke the web service. For example, you can write a generic logging handler class that logs all sent and received SOAP messages, both for the server and for the client.

Similar to the server-side SOAP handler programming, you use an XML file to specify to the `clientgen` Ant task that you want to invoke client-side SOAP message handlers. However, the XML Schema of this XML file is slightly different, as described in the following procedure.

14.8.1 Using Client-Side SOAP Message Handlers: Main Steps

The following procedure describes the high-level steps to add client-side SOAP message handlers to the client application that invokes a web service operation.

It is assumed that you have created the client application that invokes a deployed web service, and that you want to update the client application by adding client-side SOAP message handlers and handler chains. It is also assumed that you have set up an Ant-based development environment and that you have a working `build.xml` file that includes a target for running the `clientgen` Ant task. For more information, see "Developing JAX-RPC Web Service Clients" on page 6-1.
1. Design the client-side SOAP handlers and the handler chain which specifies the order in which they execute. This step is almost exactly the same as that of designing the server-side SOAP message handlers, except the perspective is from the client application, rather than a web service.

See Section 14.3, "Designing the SOAP Message Handlers and Handler Chains".

2. For each handler in the handler chain, create a Java class that extends the javax.xml.rpc.handler.GenericHandler abstract class. This step is very similar to the corresponding server-side step, except that the handler executes in a chain in the client rather than the server.

See Section 14.4, "Creating the GenericHandler Class" for details about programming a handler class. See Section 14.8.2, "Example of a Client-Side Handler Class" for an example.

3. Create the client-side SOAP handler configuration file. This XML file describes the handlers in the handler chain, the order in which they execute, and any initialization parameters that should be sent.

See Section 14.8.3, "Creating the Client-Side SOAP Handler Configuration File".

4. Update the build.xml file that builds your client application, specifying to the clientgen Ant task the name of the SOAP handler configuration file. Also ensure that the build.xml file compiles the handler files into Java classes and makes them available to your client application.

See Section 14.8.5, "Specifying the Client-Side SOAP Handler Configuration File to clientgen".

5. Rebuild your client application by running the relevant task:

```prompt> ant build-client```

When you next run the client application, the SOAP messaging handlers listed in the configuration file automatically execute before the SOAP request message is sent and after the response is received.

**Note:** You do not have to update your actual client application to invoke the client-side SOAP message handlers; as long as you specify to the clientgen Ant task the handler configuration file, the generated JAX-RPC stubs automatically take care of executing the handlers in the correct sequence.

### 14.8.2 Example of a Client-Side Handler Class

The following example shows a simple SOAP message handler class that you can configure for a client application that invokes a web service.

```java
package examples.webservices.client_handler.client;

import javax.xml.namespace.QName;
import javax.xml.rpc.handler.HandlerInfo;
import javax.xml.rpc.handler.GenericHandler;
import javax.xml.rpc.handler.MessageContext;

public class ClientHandler1 extends GenericHandler {

    private QName[] headers;

    public void init(HandlerInfo hi) {
```
public boolean handleRequest(MessageContext context) {
    System.out.println("in " + this.getClass() + " handleRequest()");
    return true;
}

public boolean handleResponse(MessageContext context) {
    System.out.println("in " + this.getClass() + " handleResponse()");
    return true;
}

public boolean handleFault(MessageContext context) {
    System.out.println("in " + this.getClass() + " handleFault()");
    return true;
}

public QName[] getHeaders() {
    return headers;
}
}

14.8.3 Creating the Client-Side SOAP Handler Configuration File

The client-side SOAP handler configuration file specifies the list of handlers in the
handler chain, the order in which they execute, the initialization parameters, and so on. See Section 14.8.4, "XML Schema for the Client-Side Handler Configuration File"
for a full description of this file.

The configuration file uses XML to describe a single handler chain that contains one or
more handlers, as shown in the following simple example:

```xml
<weblogic-wsee-clientHandlerChain
    xmlns="http://www.bea.com/ns/weblogic/90"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:j2ee="http://java.sun.com/xml/ns/j2ee">
    <handler>
        <j2ee:handler-name>clienthandler1</j2ee:handler-name>
        <j2ee:handler-class>examples.webservices.client_
            handler.client.ClientHandler1</j2ee:handler-class>
        <j2ee:init-param>
            <j2ee:param-name>ClientParam1</j2ee:param-name>
            <j2ee:param-value>value1</j2ee:param-value>
        </j2ee:init-param>
    </handler>
    <handler>
        <j2ee:handler-name>clienthandler2</j2ee:handler-name>
        <j2ee:handler-class>examples.webservices.client_
            handler.client.ClientHandler2</j2ee:handler-class>
    </handler>
</weblogic-wsee-clientHandlerChain>
```

In the example, the handler chain contains two handlers: clienthandler1 and
clienthandler2, implemented with the class names specified with the
<j2ee:handler-class> element. The two handlers execute in forward order directly
before the client application sends the SOAP request to the web service, and then in
reverse order directly after the client application receives the SOAP response from the web service.

The example also shows how to use the `<j2ee:init-param>` element to specify one or more initialization parameters to a handler.

Use the `<soap-role>`, `<soap-header>`, and `<port-name>` child elements of the `<handler>` element to specify the SOAP roles implemented by the handler, the SOAP headers processed by the handler, and the port-name element in the WSDL with which the handler is associated with, respectively.

### 14.8.4 XML Schema for the Client-Side Handler Configuration File

The following XML Schema file defines the structure of the client-side SOAP handler configuration file:

```xml
<?xml version="1.0" encoding='UTF-8'?>
<schema
targetNamespace="http://www.bea.com/ns/weblogic/90"
xmlns:wls="http://www.bea.com/ns/weblogic/90"
xmlns:j2ee="http://java.sun.com/xml/ns/j2ee"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns="http://www.w3.org/2001/XMLSchema"
elementFormDefault="qualified"
attributeFormDefault="unqualified"
>
<include schemaLocation="weblogic-j2ee.xsd"/>

<element name="weblogic-wsee-clientHandlerChain"
type="wls:weblogic-wsee-clientHandlerChainType">
  <xsd:annotation>
    <xsd:documentation>
      Defines the name of the handler. The name must be unique within the chain.
    </xsd:documentation>
  </xsd:annotation>
  <xsd:selector xpath="j2ee:handler"/>
  <xsd:field xpath="j2ee:handler-name"/>
</xsd:key>

<complexType name="weblogic-wsee-clientHandlerChainType">
  <sequence>
    <xsd:element name="handler"
type="j2ee:service-ref_handlerType"
minOccurs="0" maxOccurs="unbounded">
    </xsd:element>
  </sequence>
</complexType>
</schema>
```

A single configuration file specifies a single client-side handler chain. The root of the configuration file is `<weblogic-wsee-clientHandlerChain>`, and the file contains zero or more `<handler>` child elements, each of which describes a handler in the chain.
The structure of the <handler> element is described by the Java EE service-ref_ handlerType complex type, specified in the Java EE 1.4 web service client XML Schema http://java.sun.com/xml/ns/j2ee/j2ee_web_services_client_1_1.xsd.

14.8.5 Specifying the Client-Side SOAP Handler Configuration File to clientgen

Use the handlerChainFile attribute of the clientgen Ant task to specify the client-side SOAP handler configuration file, as shown in the following excerpt from a build.xml file:

```xml
<clientgen
    destDir="$ jig (clientclass-dir)"
    handlerChainFile="ClientHandlerChain.xml"
    packageName="examples.webservices.client_handler.client"/>
```

The JAX-RPC stubs generated by clientgen automatically ensure that the handlers described by the configuration file execute in the correct order before and after the client application invokes the web service operation.
This chapter describes how to use database web services for WebLogic Server 12.1.3. This chapter includes the following sections:

- Overview of Database Web Services
- Type Mapping Between SQL and XML

15.1 Overview of Database Web Services

Note: With the removal of JAX-RPC support in Oracle JDeveloper, there is no longer development time support for PL/SQL database web services; however, they will continue to be supported in the WebLogic Server runtime environment.

You can create Oracle TopLink database JAX-WS web service providers at design time, as described in "Creating TopLink Database Web Service Providers" in Developing Applications with Oracle JDeveloper.

In heterogeneous and disconnected environments, there is an increasing need to access stored procedures, data and metadata, through web service interfaces. Database web service technology enables web services for databases. It works in two directions:

- Database Call-in—Access database resources as a web service
- Database Call-out—Consuming external web services from the database itself

15.1.1 Database Call-in

Turning the Oracle database into a web service provider takes advantage of your investment in Java stored procedures, PL/SQL packages, Advanced Queues, pre-defined SQL queries and DML.

Note: Creating web services out of Query, Java, DML, and Advanced Queues is not supported in this release.

Client applications can query and retrieve data from Oracle databases and invoke stored procedures using standard web service protocols. There is no dependency on Oracle specific database connectivity protocols. Applications can employ any cached
WebLogic Server connection. This approach is very beneficial in heterogeneous, distributed, and non-connected environments.

Since database web services are a part of WebLogic web services, they can participate in a consistent and uniform development and deployment environment. Messages exchanged between the web service exposed database and the web service client can take advantage of all of the management features provided by WebLogic web services, such as security, reliability, auditing and logging.

The following figure illustrates web service call-in.

**Figure 15–1  Web Service Calling in to the Database**

The following steps describe the process shown in the previous figure:

1. A request for a type of database service arrives at the application server. The service endpoint implicitly specifies the type of service requested.
2. The JAX-RPC processing servlet references the SOAP libraries and XML parser to decode the request.
3. The servlet passes the request to the classes that correspond to the exposed database operations. The generated classes can represent PL/SQL packages, queries, DML, AQ Streams, or Java classes in the database.
4. The database passes the response to the JAX-RPC processing servlet, which references the SOAP libraries and XML parser to encode it.
5. A SOAP response formed in accordance with the WSDL is returned to the client.

### 15.1.2 Database Call-out

You can extend a relational database's storage, indexing, and searching capabilities to include web services. By calling a web service, the database can track, aggregate, refresh, and query dynamic data produced on-demand, such as stock prices, currency exchange rates, or weather information. An example of using the database as a service consumer would be to call an external web service from a predefined database job to obtain inventory information from multiple suppliers, then update your local inventory database. Another example is that of a Web Crawler: a database job can be scheduled to collate product and price information from a number of sources.

The following figure illustrates database call-out.
The following steps describe the process shown in the previous figure:

- **SQL and PL/SQL call specs**—Invoke a web service through a user-defined function call either directly within a SQL statement or view, or through a variable.

- **Dynamic web service invocation using the **UTL_DBWS** PL/SQL package**. A Call object can be dynamically created based on a WSDL and subsequently, web services operations can be invoked.
  
  Oracle Database PL/SQL Packages and Types Reference provides more information on using the **UTL_DBWS** PL/SQL package.

- **Pure Java static proxy class**—Generate a client proxy class which uses JAX-RPC. This method simplifies the web service invocation as the location of the service is already known without needing to look up the service in the UDDI registry. The client proxy class does all of the work to construct the SOAP request, including marshalling and unmarshalling parameters.

- **Pure Java using DII (dynamic invocation interface) over JAX-RPC**—Dynamic invocation provides the ability to construct the SOAP request and access the service without the client proxy.

Which method to use depends on whether you want to execute from SQL or PL/SQL, from Java classes, or whether the service is known ahead of time (static invocation) or only at runtime (DII).

### 15.2 Type Mapping Between SQL and XML

The following sections describe the type mappings between SQL and XML for call-ins and call-outs when the web service is known ahead of time (static invocation).

When the web service is known at runtime you can use only the Dynamic Invocation Interface (DII) or the **UTL_DBWS** PL/SQL package.

#### 15.2.1 SQL to XML Type Mappings for Web Service Call-Ins

In a database web service call-in, a SQL operation, such as a PL/SQL stored procedure or a SQL statement, is mapped into one or more web service operations. The parameters to the SQL operation are mapped from SQL types into XML types.

**Note:** The reason there may be more than one operation is because OracleAS web services may be providing additional data representation choices for the SQL values in XML, such as different representations of SQL result sets.
The following table illustrates the SQL-to-XML mappings for web service call-ins. The first column lists the SQL types. The second column of the table, XML Type (Literal), shows SQL-to-XML type mappings for the default literal value of the use attribute. The third column, XML Type (Encoded), shows the mappings for the encoded value of the use attribute. The literal and encoded values refer to the rules for encoding the body of a SOAP message.

### Table 15–1 SQL-to-XML Type Mappings for Web Services Call-ins

<table>
<thead>
<tr>
<th>SQL Type</th>
<th>XML Type (Literal)</th>
<th>XML Type (Encoded)</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>INTEGER</td>
<td>int</td>
<td>int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>double</td>
<td>double</td>
</tr>
<tr>
<td>NUMBER</td>
<td>decimal</td>
<td>decimal</td>
</tr>
<tr>
<td>VARCHAR2</td>
<td>string</td>
<td>string</td>
</tr>
<tr>
<td>DATE</td>
<td>dateTime</td>
<td>dateTime</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>dateTime</td>
<td>dateTime</td>
</tr>
<tr>
<td>BLOB</td>
<td>byte[]</td>
<td>byte[]</td>
</tr>
<tr>
<td>CLOB</td>
<td>String</td>
<td>String</td>
</tr>
<tr>
<td>LONG</td>
<td>String</td>
<td>String</td>
</tr>
<tr>
<td>RAW</td>
<td>byte[]</td>
<td>byte[]</td>
</tr>
<tr>
<td>Primitive PL/SQL indexby table</td>
<td>Array</td>
<td>Array</td>
</tr>
<tr>
<td>PL/SQL Boolean</td>
<td>boolean</td>
<td>boolean</td>
</tr>
<tr>
<td>PL/SQL indexby table</td>
<td>complexType</td>
<td>complexType</td>
</tr>
<tr>
<td>PL/SQL record</td>
<td>complexType</td>
<td>complexType</td>
</tr>
<tr>
<td>REF CURSOR (nameBeans)</td>
<td>Array</td>
<td>Array</td>
</tr>
<tr>
<td>REF CURSOR nameXML)</td>
<td>any</td>
<td>test_xml</td>
</tr>
<tr>
<td>REF CURSOR nameMLRowSet</td>
<td>swaRef</td>
<td>test_xml</td>
</tr>
<tr>
<td>SQL object</td>
<td>complexType</td>
<td>complexType</td>
</tr>
<tr>
<td>SQL table</td>
<td>complexType</td>
<td>complexType</td>
</tr>
<tr>
<td>SYS.XMLTYPE</td>
<td>any</td>
<td>test_xml</td>
</tr>
</tbody>
</table>

**Note:** If National Language Support (also known as "NLS" or "Globalization Support") characters are used in a SQL SYS.XMLTYPE value, they may not be properly handled.

A query or a PL/SQL function returning REF CURSOR will be mapped into the three methods listed below, where name is the name of the query or the PL/SQL function.

- **nameBeans**—This method returns an array, where each element is an instance of an XSD complex type that represents one row in the cursor. A complex type sub-element corresponds to a column in that row.
nameXMLRowSet—This method returns a swaRef or text_xml response that contains an OracleWebRowSet instance in XML format.

nameXML—this method returns an XML any or text_xml response that contains an Oracle XDB row set.

Both OUT and IN OUT PL/SQL parameters are mapped to IN OUT parameters in the WSDL file.

Note that Table 15–1 provides two different mappings: one for literal and another for encoded use. The default mapping is literal. From a database web service's perspective, there is no special reason why encoded should be used. The mapping for encoded is provided in case you encounter scenarios which call for the encoded use setting. All of the descriptions in this chapter assume that you will be using the literal use setting unless otherwise specified.

15.2.2 XML-to-SQL Type Mapping for Web Service Call-outs

In database web services call-outs, XML types are mapped into SQL types. The following table lists the XML-to-SQL type mappings used in call-outs.

<table>
<thead>
<tr>
<th>XML Type</th>
<th>SQL Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>NUMBER</td>
</tr>
<tr>
<td>float</td>
<td>NUMBER</td>
</tr>
<tr>
<td>double</td>
<td>NUMBER</td>
</tr>
<tr>
<td>decimal</td>
<td>NUMBER</td>
</tr>
<tr>
<td>dateTime</td>
<td>DATE</td>
</tr>
<tr>
<td>String</td>
<td>VARCHAR2</td>
</tr>
<tr>
<td>byte[]</td>
<td>RAW</td>
</tr>
<tr>
<td>complexType</td>
<td>SQL OBJECT</td>
</tr>
<tr>
<td>Array</td>
<td>SQL TABLE</td>
</tr>
<tr>
<td>test_xml</td>
<td>XML Type</td>
</tr>
</tbody>
</table>
This appendix describes the pre-packaged WS-Policy files that contain typical reliable messaging assertions that you can use to support reliable messaging with WebLogic Java API for XML-based RPC (JAX-RPC) web services for WebLogic Server 12.1.3.

This appendix includes the following sections:

- DefaultReliability1.1.xml (WS-Policy File)
- Reliability1.1_SequenceTransportSecurity.xml (WS-Policy File)
- Reliability1.1_SequenceSTR.xml (WS-Policy File)
- Reliability1.0_1.1.xml (WS-Policy.xml File)
- DefaultReliability.xml (WS-Policy File) [Deprecated]
- LongRunningReliability.xml (WS-Policy File) [Deprecated]

A.1 DefaultReliability1.1.xml (WS-Policy File)

```xml
<?xml version="1.0"?>
<wsp:Policy
>
    <wsrmp:RMAssertion
        xmlns:wsrmp="http://docs.oasis-open.org/ws-rx/wsrmp/200702"
    >
        <wsrmp:DeliveryAssurance>
            <wsp:Policy>
                <wsrmp:ExactlyOnce />
            </wsp:Policy>
        </wsrmp:DeliveryAssurance>
    </wsrmp:RMAssertion>
</wsp:Policy>
```
A.2 Reliability1.1_SequenceTransportSecurity.xml (WS-Policy File)

```xml
  <wsp:ExactlyOnce/>
</wsp:Policy>
</wsp:Policy>
```

A.3 Reliability1.1_SequenceSTR.xml (WS-Policy File)

The Reliability1.1_SequenceSTR.xml file specifies that in order to secure messages in a reliable sequence, the runtime will use the wsse:SecurityTokenReference that is referenced in the CreateSequence message. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion 1.1 at http://docs.oasis-open.org/ws-rx/wsrmp/200702/wsrmp-1.1-spec-os-01.pdf.

```xml
  <wsp:ExactlyOnce/>
</wsp:Policy>
</wsp:Policy>
```

A.4 Reliability1.0_1.1.xml (WS-Policy.xml File)

The Reliability1.0_1.1.xml file combines 1.1 and 1.0 WS-Reliable Messaging policy assertions. This sample relies on smart policy selection to determine the policy assertion that is applied at runtime. For more information about smart policy selection, see Section 8.5.3, "Using Multiple Policy Alternatives".

**Note:** The 1.0 web service reliable messaging assertions are prefixed by wsrmp10.

```xml
<wsp:ExactlyOne>
  <wsp:All>
    <wsrmp10:RMAssertion>
      ...
    </wsrmp10:RMAssertion>
  </wsp:All>
</wsp:ExactlyOne>
```
A.5 DefaultReliability.xml (WS-Policy File) [Deprecated]

This WS-Policy file is deprecated. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion Version 1.0 at http://schemas.xmlsoap.org/ws/2005/02/rm/policy/. In the current release, many of the reliable messaging policy assertions are managed through JWS annotations or configuration.

The DefaultReliability.xml WS-Policy file specifies typical values for the reliable messaging policy assertions, such as inactivity timeout of 10 minutes, acknowledgement interval of 200 milliseconds, and base retransmission interval of 3 seconds.

```xml
<?xml version="1.0"?>
<wsp:Policy
    xmlns:wrm="http://schemas.xmlsoap.org/ws/2005/02/rm/policy"
    xmlns:beapolicy="http://www.bea.com/wsrmp/policy"
>
    <wrm:RMAssertion>
        <wrm:InactivityTimeout
            Milliseconds="600000" />
        <wrm:BaseRetransmissionInterval
            Milliseconds="3000" />
        <wrm:ExponentialBackoff />
        <wrm:AcknowledgementInterval
            Milliseconds="200" />
        <beapolicy:Expires Expires="P1D" optional="true"/>
    </wrm:RMAssertion>
</wsp:Policy>
```
This WS-Policy file is deprecated. The web service reliable messaging assertions are based on WS Reliable Messaging Policy Assertion Version 1.0 at http://schemas.xmlsoap.org/ws/2005/02/rm/policy/. In the current release, many of the reliable messaging policy assertions are managed through JWS annotations or configuration.

The LongRunningReliability.xml WS-Policy files specifies values that are similar to the DefaultReliability.xml WS-Policy file, except that it specifies a much longer activity timeout interval (24 hours). See Section A.6, "LongRunningReliability.xml (WS-Policy File) [ Deprecated ]".

```xml
<?xml version="1.0"?>
<wsp:Policy
 xmlns:wsrm="http://schemas.xmlsoap.org/ws/2005/02/rm/policy"
 xmlns:beapolicy="http://www.bea.com/wsrm/policy"
>
 <wsrm:RMAssertion>
  <wsrm:InactivityTimeout Milliseconds="86400000" />
  <wsrm:BaseRetransmissionInterval Milliseconds="3000" />
  <wsrm:ExponentialBackoff />
  <wsrm:AcknowledgementInterval Milliseconds="200" />
  <beapolicy:Expires Expires="P1M" optional="true"/>
 </wsrm:RMAssertion>
</wsp:Policy>
```
