

Oracle® Fusion Middleware

Developing Applications for Oracle WebLogic Server

12c (12.2.1)

E55175-02

November 2015

This document describes building WebLogic Server e-commerce applications using the Java Platform, Enterprise Edition 7.

Copyright © 2007, 2015, Oracle and/or its affiliates. All rights reserved.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

1 Overview of WebLogic Server Application Development	
1.1 Document Scope and Audience	1-1
1.2 WebLogic Server and the Java EE Platform	1-2
1.2.1 Java EE 7 Programming Model: Increased Productivity	1-2
1.2.2 WebLogic Server and Java EE Applications	1-2
1.3 Overview of Java EE Applications and Modules	1-2
1.4 Web Application Modules	1-3
1.4.1 Servlets	1-3
1.4.2 JavaServer Pages	1-3
1.4.3 More Information on Web Application Modules	1-3
1.5 Enterprise JavaBean Modules	1-4
1.5.1 EJB Documentation in WebLogic Server	1-4
1.5.2 Additional EJB Information	1-4
1.6 Connector Modules	1-4
1.7 Enterprise Applications	1-5
1.7.1 Java EE Programming Model	1-5
1.7.2 Packaging and Deployment Overview	1-5
1.8 WebLogic Web Services	1-6
1.9 JMS and JDBC Modules	1-7
1.10 WebLogic Diagnostic Framework Modules	1-7
1.10.1 Using an External Diagnostics Descriptor	1-7
1.10.1.1 Defining an External Diagnostics Descriptor	1-7
1.11 Coherence Grid Archive (GAR) Modules	1-8
1.12 Bean Validation	1-8
1.13 XML Deployment Descriptors	1-9
1.13.1 Automatically Generating Deployment Descriptors	1-14
1.13.2 EJBCGen	1-14
1.13.3 Java-based Command-line Utilities	1-14
1.13.4 Upgrading Deployment Descriptors From Previous Releases of Java EE and WebLogic Server	1-15
1.14 Deployment Plans	1-15
1.15 Development Tools	1-16

1.15.1	Java API Reference and the wls-api.jar File	1-16
1.15.1.1	Using the wls-api.jar File	1-17
1.15.1.2	Using the weblogic.jar File	1-17
1.15.2	Apache Ant	1-17
1.15.2.1	Using a Third-Party Version of Ant	1-18
1.15.2.2	Changing the Ant Heap Size	1-18
1.15.3	Source Code Editor or IDE	1-18
1.15.4	Database System and JDBC Driver	1-18
1.15.5	Web Browser	1-19
1.15.6	Third-Party Software	1-19
1.16	New and Changed Features in this Release	1-19

2 Using Ant Tasks to Configure and Use a WebLogic Server Domain

2.1	Overview of Configuring and Starting Domains Using Ant Tasks	2-1
2.2	Starting Servers and Creating Domains Using the wlservlet Ant Task	2-2
2.2.1	Basic Steps for Using wlservlet	2-2
2.2.2	Sample build.xml Files for wlservlet	2-3
2.2.3	wlservlet Ant Task Reference	2-3
2.3	Configuring a WebLogic Server Domain Using the wlconfig Ant Task	2-6
2.3.1	What the wlconfig Ant Task Does	2-6
2.3.2	Basic Steps for Using wlconfig	2-7
2.3.3	wlconfig Ant Task Reference	2-7
2.3.4	Main Attributes	2-7
2.3.5	Nested Elements	2-8
2.3.5.1	create	2-9
2.3.5.2	delete	2-9
2.3.5.3	set	2-9
2.3.5.4	get	2-10
2.3.5.5	query	2-10
2.3.5.6	invoke	2-11
2.3.6	Example of Creating a Security Realm with the wlconfig Ant Task	2-11
2.4	Using the libclasspath Ant Task	2-12
2.4.1	libclasspath Task Definition	2-12
2.4.2	libclasspath Ant Task Reference	2-12
2.4.3	Main libclasspath Attributes	2-12
2.4.4	Nested libclasspath Elements	2-13
2.4.4.1	librarydir	2-13
2.4.4.2	library	2-13
2.4.5	Example libclasspath Ant Task	2-13

3 Using the WebLogic Maven Plug-In

3.1	Installing Maven	3-1
3.2	Configuring the WebLogic Maven Plug-In	3-2
3.2.1	How to use the WebLogic Maven Plug-in	3-2
3.2.2	Basic Configuration POM File	3-5
3.3	Maven Plug-In Goals	3-6
3.3.1	appc	3-7

3.3.2	create-domain.....	3-10
3.3.3	deploy	3-13
3.3.4	distribute-app	3-17
3.3.5	install	3-20
3.3.6	list-apps	3-25
3.3.7	purge-tasks	3-27
3.3.8	redeploy	3-28
3.3.9	remove-domain.....	3-32
3.3.10	start-app	3-33
3.3.11	start-server	3-35
3.3.12	stop-app.....	3-37
3.3.13	stop-server	3-40
3.3.14	undeploy	3-42
3.3.15	uninstall.....	3-45
3.3.16	update-app.....	3-46
3.3.17	wlst.....	3-49
3.3.18	wlst-client.....	3-53
3.3.19	ws-clientgen.....	3-58
3.3.20	wsgen.....	3-63
3.3.21	wsimport	3-66
3.3.22	ws-wsdlc	3-72
3.3.23	ws-jwsc	3-75

4 Creating a Split Development Directory Environment

4.1	Overview of the Split Development Directory Environment	4-1
4.1.1	Source and Build Directories.....	4-2
4.1.2	Deploying from a Split Development Directory	4-3
4.1.3	Split Development Directory Ant Tasks	4-4
4.2	Using the Split Development Directory Structure: Main Steps	4-4
4.3	Organizing Java EE Components in a Split Development Directory.....	4-5
4.3.1	Source Directory Overview	4-6
4.3.2	Enterprise Application Configuration.....	4-8
4.3.3	Web Applications	4-8
4.3.4	EJBs	4-9
4.3.5	Important Notes Regarding EJB Descriptors.....	4-10
4.4	Organizing Shared Classes in a Split Development Directory	4-11
4.4.1	Shared Utility Classes	4-11
4.4.2	Third-Party Libraries.....	4-11
4.4.3	Class Loading for Shared Classes.....	4-12
4.5	Generating a Basic build.xml File Using weblogic.BuildXMLGen.....	4-12
4.5.1	weblogic.BuildXMLGen Syntax	4-13
4.6	Developing Multiple-EAR Projects Using the Split Development Directory	4-14
4.6.1	Organizing Libraries and Classes Shared by Multiple EARs.....	4-14
4.6.2	Linking Multiple build.xml Files.....	4-15
4.7	Best Practices for Developing WebLogic Server Applications.....	4-15

5 Building Applications in a Split Development Directory

5.1	Compiling Applications Using wlcompile.....	5-1
5.1.1	Using includes and excludes Properties.....	5-2
5.1.2	wlcompile Ant Task Attributes.....	5-2
5.1.3	Nested javac Options	5-2
5.1.4	Setting the Classpath for Compiling Code	5-2
5.1.5	Library Element for wlcompile and wlappp.....	5-3
5.2	Building Modules and Applications Using wlappp	5-3
5.2.1	wlappp Ant Task Attributes	5-4
5.2.2	wlappp Ant Task Syntax	5-5
5.2.3	Syntax Differences between appc and wlappp.....	5-5
5.2.4	weblogic.appc Reference	5-5
5.2.5	weblogic.appc Syntax.....	5-5
5.2.6	weblogic.appc Options	5-5

6 Deploying and Packaging from a Split Development Directory

6.1	Deploying Applications Using wldeploy.....	6-1
6.2	Packaging Applications Using wlpackage.....	6-1
6.2.1	Archive versus Exploded Archive Directory.....	6-1
6.2.2	wlpackage Ant Task Example.....	6-2
6.2.3	wlpackage Ant Task Attribute Reference	6-2

7 Developing Applications for Production Redeployment

7.1	What is Production Redeployment?	7-1
7.2	Supported and Unsupported Application Types	7-1
7.2.1	Additional Application Support.....	7-2
7.3	Programming Requirements and Conventions.....	7-2
7.3.1	Applications Should Be Self-Contained	7-2
7.3.2	Versioned Applications Access the Current Version JNDI Tree by Default.....	7-3
7.3.3	Security Providers Must Be Compatible	7-3
7.3.4	Applications Must Specify a Version Identifier	7-3
7.3.5	Applications Can Access Name and Identifier	7-3
7.3.6	Client Applications Use Same Version when Possible	7-3
7.4	Assigning an Application Version	7-4
7.4.1	Application Version Conventions	7-4
7.5	Upgrading Applications to Use Production Redeployment	7-4
7.6	Accessing Version Information.....	7-5

8 Using Java EE Annotations and Dependency Injection

8.1	Annotation Processing	8-1
8.1.1	Annotation Parsing.....	8-1
8.1.2	Deployment View of Annotation Configuration	8-2
8.1.3	Compiling Annotated Classes	8-2
8.1.4	Dynamic Annotation Updates	8-2
8.2	Dependency Injection of Resources	8-2
8.2.1	Application Life Cycle Annotation Methods.....	8-3

8.3	Standard JDK Annotations	8-3
8.3.1	javax.annotation.PostConstruct	8-4
8.3.2	javax.annotation.PreDestroy	8-4
8.3.3	javax.annotation.Resource	8-5
8.3.4	javax.annotation.Resources	8-6
8.4	Standard Security-Related JDK Annotations	8-6
8.4.1	javax.annotation.security.DeclareRoles	8-7
8.4.2	javax.annotation.security.DenyAll	8-7
8.4.3	javax.annotation.security.PermitAll	8-7
8.4.4	javax.annotation.security.RolesAllowed	8-7
8.4.5	javax.annotation.security.RunAs	8-8

9 Using Contexts and Dependency Injection for the Java EE Platform

9.1	About CDI for the Java EE Platform	9-2
9.1.1	CDI 1.1 Examples	9-2
9.1.2	CDI 1.0 Example	9-3
9.2	Defining a Managed Bean	9-3
9.3	Injecting a Bean	9-3
9.4	Defining the Scope of a Bean	9-4
9.5	Overriding the Scope of a Bean at the Point of Injection	9-5
9.6	Using Qualifiers	9-5
9.6.1	Defining Qualifiers for Implementations of a Bean Type	9-5
9.6.2	Applying Qualifiers to a Bean	9-7
9.6.3	Injecting a Qualified Bean	9-7
9.7	Providing Alternative Implementations of a Bean Type	9-8
9.7.1	Defining an Alternative Implementation of a Bean Type	9-9
9.7.2	Selecting an Alternative Implementation of a Bean Type for an Application	9-9
9.8	Applying a Scope and Qualifiers to a Session Bean	9-10
9.8.1	Applying a Scope to a Session Bean	9-10
9.8.2	Applying Qualifiers to a Session Bean	9-11
9.9	Using Producer Methods, Disposer Methods, and Producer Fields	9-11
9.9.1	Defining a Producer Method	9-11
9.9.2	Defining a Disposer Method	9-11
9.9.3	Defining a Producer Field	9-12
9.10	Initializing and Preparing for the Destruction of a Managed Bean	9-13
9.10.1	Initializing a Managed Bean	9-13
9.10.2	Preparing for the Destruction of a Managed Bean	9-13
9.11	Intercepting Method Invocations and Life Cycle Events of Bean Classes	9-14
9.11.1	Defining an Interceptor Binding Type	9-14
9.11.2	Defining an Interceptor Class	9-15
9.11.3	Identifying Methods for Interception	9-17
9.11.4	Enabling an Interceptor	9-17
9.12	Decorating a Managed Bean Class	9-18
9.12.1	Defining a Decorator Class	9-19
9.12.2	Enabling a Decorator Class	9-20
9.13	Assigning an EL Name to a CDI Bean Class	9-21
9.14	Defining and Applying Stereotypes	9-22

9.14.1	Defining a Stereotype	9-22
9.14.2	Applying Stereotypes to a Bean.....	9-23
9.15	Using Events for Communications Between Beans	9-23
9.15.1	Defining an Event Type	9-24
9.15.2	Sending an Event	9-24
9.15.3	Handling an Event.....	9-25
9.16	Injecting a Predefined Bean	9-26
9.17	Injecting and Qualifying Resources	9-27
9.18	Using CDI With JCA Technology	9-29
9.19	Configuring a CDI Application	9-30
9.20	Supporting Third-Party Portable Extensions.....	9-31
9.21	Enabling and Disabling Implicit Bean Discovery	9-31

10 Java API for JSON Processing

10.1	About JavaScript Object Notation (JSON).....	10-1
10.2	Object Model API.....	10-2
10.2.1	Creating an Object Model from JSON Data.....	10-2
10.2.2	Creating an Object Model from Application Code.....	10-2
10.2.3	Navigating an Object Model	10-3
10.2.4	Writing an Object Model to a Stream	10-5
10.3	Streaming API	10-5
10.3.1	Reading JSON Data Using a Parser.....	10-6
10.3.2	Writing JSON Data Using a Generator.....	10-7

11 Understanding WebLogic Server Application Classloading

11.1	Java Classloading	11-1
11.1.1	Java Classloader Hierarchy	11-1
11.1.2	Loading a Class	11-2
11.1.3	prefer-web-inf-classes Element.....	11-2
11.1.4	Changing Classes in a Running Program	11-3
11.1.5	Class Caching With the Policy Classloader	11-3
11.2	WebLogic Server Application Classloading	11-3
11.2.1	Overview of WebLogic Server Application Classloading	11-4
11.2.2	Application Classloader Hierarchy.....	11-4
11.2.3	Custom Module Classloader Hierarchies	11-5
11.2.4	Declaring the Classloader Hierarchy	11-6
11.2.5	User-Defined Classloader Restrictions	11-8
11.2.5.1	Servlet Reloading Disabled	11-8
11.2.5.2	Nesting Depth	11-8
11.2.5.3	Module Types	11-8
11.2.5.4	Duplicate Entries	11-9
11.2.5.5	Interfaces	11-9
11.2.5.6	Call-by-Value Semantics.....	11-9
11.2.5.7	In-Flight Work.....	11-9
11.2.5.8	Development Use Only	11-9
11.2.6	Individual EJB Classloader for Implementation Classes	11-9
11.2.7	Application Classloading and Pass-by-Value or Reference	11-10

11.2.8	Using a Filtering ClassLoader.....	11-11
11.2.9	What is a Filtering ClassLoader.....	11-11
11.2.10	Configuring a Filtering ClassLoader	11-12
11.2.11	Resource Loading Order.....	11-12
11.3	Resolving Class References Between Modules and Applications	11-13
11.3.1	About Resource Adapter Classes	11-13
11.3.2	Packaging Shared Utility Classes	11-14
11.3.3	Manifest Class-Path.....	11-14
11.4	Using the Classloader Analysis Tool (CAT)	11-15
11.4.1	Opening the CAT Interface	11-15
11.4.2	How CAT Analyzes Classes.....	11-16
11.4.3	Identifying Class References through Manifest Hierarchies.....	11-16
11.5	Sharing Applications and Modules By Using Java EE Libraries	11-17
11.6	Adding JARs to the Domain /lib Directory.....	11-18

12 Creating Shared Java EE Libraries and Optional Packages

12.1	Overview of Shared Java EE Libraries and Optional Packages	12-1
12.1.1	Optional Packages	12-2
12.1.2	Library Directories.....	12-3
12.1.3	Versioning Support for Libraries.....	12-3
12.1.4	Shared Java EE Libraries and Optional Packages Compared	12-4
12.1.5	Additional Information.....	12-4
12.2	Creating Shared Java EE Libraries.....	12-5
12.2.1	Assembling Shared Java EE Library Files	12-5
12.2.2	Assembling Optional Package Class Files	12-6
12.2.3	Editing Manifest Attributes for Shared Java EE Libraries.....	12-6
12.2.4	Packaging Shared Java EE Libraries for Distribution and Deployment.....	12-8
12.3	Referencing Shared Java EE Libraries in an Enterprise Application.....	12-8
12.3.1	Overriding context-roots Within a Referenced Enterprise Library.....	12-10
12.3.2	URIs for Shared Java EE Libraries Deployed As a Standalone Module.....	12-11
12.4	Referencing Optional Packages from a Java EE Application or Module.....	12-11
12.5	Using weblogic.appmerge to Merge Libraries	12-13
12.5.1	Using weblogic.appmerge from the CLI.....	12-13
12.5.2	Using weblogic.appmerge as an Ant Task.....	12-14
12.6	Integrating Shared Java EE Libraries with the Split Development Directory Environment	12-14
12.7	Deploying Shared Java EE Libraries and Dependent Applications	12-14
12.8	Web Application Shared Java EE Library Information	12-14
12.9	Using WebApp Libraries With Web Applications.....	12-15
12.10	Accessing Registered Shared Java EE Library Information with LibraryRuntimeMBean	12-16
12.11	Order of Precedence of Modules When Referencing Shared Java EE Libraries.....	12-16
12.12	Best Practices for Using Shared Java EE Libraries	12-17

13 Programming Application Life Cycle Events

13.1	Understanding Application Life Cycle Events.....	13-1
------	--	------

13.2	Registering Events in weblogic-application.xml.....	13-2
13.3	Programming Basic Life Cycle Listener Functionality	13-2
13.3.1	Configuring a Role-Based Application Life Cycle Listener.....	13-4
13.4	Examples of Configuring Life Cycle Events with and without the URI Parameter	13-4
13.5	Understanding Application Life Cycle Event Behavior During Re-deployment.....	13-5
13.6	Programming Application Version Life Cycle Events	13-5
13.6.1	Understanding Application Version Life Cycle Event Behavior.....	13-5
13.6.2	Types of Application Version Life Cycle Events.....	13-6
13.6.3	Example of Production Deployment Sequence When Using Application Version Life Cycle Events.....	13-6
14	Programming Context Propagation	
14.1	Understanding Context Propagation.....	14-1
14.2	Programming Context Propagation: Main Steps	14-2
14.3	Programming Context Propagation in a Client.....	14-2
14.4	Programming Context Propagation in an Application	14-4
15	Programming JavaMail with WebLogic Server	
15.1	Overview of Using JavaMail with WebLogic Server Applications	15-1
15.2	Understanding JavaMail Configuration Files.....	15-2
15.3	Configuring JavaMail for WebLogic Server.....	15-2
15.4	Sending Messages with JavaMail	15-2
15.5	Reading Messages with JavaMail	15-3
16	Threading and Clustering Topics	
16.1	Using Threads in WebLogic Server.....	16-1
16.2	Using the Work Manager API for Lower-Level Threading.....	16-2
16.3	Programming Applications for WebLogic Server Clusters	16-2
17	Developing OSGi Bundles for WebLogic Server Applications	
17.1	Understanding OSGi	17-1
17.2	Features Provided in WebLogic Server OSGi Implementation	17-2
17.3	Configuring the OSGi Framework	17-3
17.3.1	Configuring OSGi Framework Instances	17-3
17.3.1.1	Configuring OSGi Framework Instance From Administration Console	17-4
17.3.1.2	Configuring OSGi Framework Instance From config.xml	17-5
17.3.1.3	Configuring OSGi Framework Instance From WLST	17-5
17.3.1.4	Configuring OSGi Framework Instance from a Java Program.....	17-6
17.3.1.5	Parameter Required for Installing Bundles in the Framework.....	17-8
17.3.2	Configuring OSGi Framework Persistence.....	17-9
17.3.3	Using OSGi Services.....	17-9
17.4	Creating OSGi Bundles	17-9
17.5	Deploying OSGi Bundles.....	17-9
17.5.1	Preparing to Deploy an OSGi Bundle on a Target System.....	17-9
17.5.1.1	Preparing to Deploy Bundles as Enterprise Applications.....	17-10
17.5.1.2	Preparing to Deploy Bundles as Web Applications	17-10

17.5.1.3	Global Work Managers.....	17-11
17.5.1.4	Global Data Sources.....	17-11
17.5.2	Deploying OSGi Bundles in the osgi-lib Directory.....	17-12
17.5.2.1	Setting the Start Level and Run Level for a Bundle.....	17-13
17.6	Accessing Deployed Bundle Objects From JNDI.....	17-13
17.7	Using OSGi Logging Via WebLogic Server.....	17-15
17.8	Configuring a Filtering ClassLoader for OSGi Bundles.....	17-15
17.9	OSGi Example.....	17-16

18 Using the WebSocket Protocol in WebLogic Server

18.1	Understanding the WebSocket Protocol.....	18-2
18.1.1	Limitations of the HTTP Request-Response Model.....	18-2
18.1.2	WebSocket Endpoints.....	18-2
18.1.3	Handshake Requests in the WebSocket Protocol.....	18-3
18.1.4	Messaging and Data Transfer in the WebSocket Protocol.....	18-3
18.2	Understanding the WebLogic Server WebSocket Implementation.....	18-3
18.2.1	WebSocket Protocol Implementation.....	18-4
18.2.2	WebLogic WebSocket Java API.....	18-4
18.2.3	Protocol Fallback for WebSocket Messaging.....	18-4
18.2.4	Sample WebSocket Applications.....	18-5
18.3	Overview of Creating a WebSocket Application.....	18-5
18.4	Creating an Endpoint.....	18-5
18.4.1	Creating an Annotated Endpoint.....	18-5
18.4.2	Creating a Programmatic Endpoint.....	18-7
18.4.3	Specifying the Path Within an Application to a Programmatic Endpoint.....	18-7
18.5	Handling Life Cycle Events for a WebSocket Connection.....	18-8
18.5.1	Handling Life Cycle Events in an Annotated WebSocket Endpoint.....	18-8
18.5.1.1	Handling a Connection Opened Event.....	18-9
18.5.1.2	Handling a Message Received Event.....	18-9
18.5.1.3	Handling an Error Event.....	18-11
18.5.1.4	Handling a Connection Closed Event.....	18-12
18.5.2	Handling Life Cycle Events in a Programmatic WebSocket Endpoint.....	18-12
18.6	Defining, Injecting, and Accessing a Resource for a WebSocket Endpoint.....	18-13
18.7	Sending a Message.....	18-15
18.7.1	Sending a Message to a Single Peer of an Endpoint.....	18-15
18.7.2	Sending a Message to All Peers of an Endpoint.....	18-16
18.7.3	Ensuring Thread Safety for WebSocket Endpoints.....	18-17
18.8	Encoding and Decoding a WebSocket Message.....	18-17
18.8.1	Encoding a Java Object as a WebSocket Message.....	18-18

Preface

This preface describes the document accessibility features and conventions used in this guide—*Developing Applications for Oracle WebLogic Server*.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
<i>italic</i>	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Overview of WebLogic Server Application Development

This chapter provides an overview of WebLogic Server applications and basic concepts.

This chapter includes the following sections:

- [Section 1.1, "Document Scope and Audience"](#)
- [Section 1.2, "WebLogic Server and the Java EE Platform"](#)
- [Section 1.3, "Overview of Java EE Applications and Modules"](#)
- [Section 1.4, "Web Application Modules"](#)
- [Section 1.5, "Enterprise JavaBean Modules"](#)
- [Section 1.6, "Connector Modules"](#)
- [Section 1.7, "Enterprise Applications"](#)
- [Section 1.8, "WebLogic Web Services"](#)
- [Section 1.9, "JMS and JDBC Modules"](#)
- [Section 1.10, "WebLogic Diagnostic Framework Modules"](#)
- [Section 1.11, "Coherence Grid Archive \(GAR\) Modules."](#)
- [Section 1.12, "Bean Validation."](#)
- [Section 1.13, "XML Deployment Descriptors"](#)
- [Section 1.14, "Deployment Plans"](#)
- [Section 1.15, "Development Tools"](#)
- [Section 1.16, "New and Changed Features in this Release"](#)

1.1 Document Scope and Audience

This document is written for application developers who want to build WebLogic Server applications using the Java Platform, Enterprise Edition (Java EE). It is assumed that readers know Web technologies, object-oriented programming techniques, and the Java programming language.

WebLogic Server applications are created by Java programmers, Web designers, and application assemblers. Programmers and designers create modules that implement the business and presentation logic for the application. Application assemblers assemble the modules into applications that are ready to deploy on WebLogic Server.

1.2 WebLogic Server and the Java EE Platform

WebLogic Server implements Java Platform, Enterprise Edition (Java EE) Version 7 technologies (see <http://www.oracle.com/technetwork/java/javaee/overview/index.html>). Java EE is the standard platform for developing multi-tier enterprise applications based on the Java programming language. The technologies that make up Java EE were developed collaboratively by several software vendors.

1.2.1 Java EE 7 Programming Model: Increased Productivity

An important aspect of the Java EE programming model is the continued evolution of metadata annotations. Annotations simplify the application development process by allowing a developer to specify within the Java class itself how the application component behaves in the container, requests for dependency injection, and so on. Annotations are an alternative to deployment descriptors that were required by older versions of enterprise applications.

With Java EE 7, there is a continuing focus on ease of development. There is less code to write – much of the boilerplate code has been removed, defaults are used whenever possible, and annotations are used extensively to reduce the need for deployment descriptors. Also, improvements to development tooling and open source support expand developer choices and simplify creation of development environments.

For information about all the new Java EE 7 updates supported in WebLogic Server, see "Java EE 7 Support" in *What's New in Oracle WebLogic Server 12.2.1*.

1.2.2 WebLogic Server and Java EE Applications

WebLogic Server Java EE applications are based on standardized, modular components. WebLogic Server provides a complete set of services for those modules and handles many details of application behavior automatically, without requiring programming. Java EE defines module behaviors and packaging in a generic, portable way, postponing run-time configuration until the module is actually deployed on an application server.

Java EE includes deployment specifications for Web applications, EJB modules, Web services, enterprise applications, client applications, and connectors. Java EE does not specify *how* an application is deployed on the target server—only how a standard module or application is packaged. For each module type, the specifications define the files required and their location in the directory structure.

Java is platform independent, so you can edit and compile code on any platform, and test your applications on development WebLogic Servers running on other platforms. For example, it is common to develop WebLogic Server applications on a PC running Windows or Linux, regardless of the platform where the application is ultimately deployed.

For more information, refer to the specifications on the Java EE Technologies page: <http://www.oracle.com/technetwork/java/javaee/tech/index-jsp-142185.html>.

1.3 Overview of Java EE Applications and Modules

A WebLogic Server Java EE application consists of one of the following modules or applications running on WebLogic Server:

- Web application modules—HTML pages, servlets, JavaServer Pages, and related files. See [Section 1.4, "Web Application Modules"](#).

- Enterprise JavaBeans (EJB) modules—entity beans, session beans, and message-driven beans. See [Section 1.5, "Enterprise JavaBean Modules"](#).
- Connector modules—resource adapters. See [Section 1.6, "Connector Modules"](#).
- Enterprise applications—Web application modules, EJB modules, resource adapters and Web services packaged into an application. See [Section 1.7, "Enterprise Applications"](#).
- Web services—See [Section 1.8, "WebLogic Web Services"](#).

A WebLogic application can also include the following WebLogic-specific modules:

- JDBC and JMS modules—See [Section 1.9, "JMS and JDBC Modules"](#).
- WebLogic Diagnostic FrameWork (WLDF) modules—See [Section 1.10, "WebLogic Diagnostic Framework Modules"](#).
- Coherence Grid Archive (GAR) Modules—See [Section 1.11, "Coherence Grid Archive \(GAR\) Modules."](#)

1.4 Web Application Modules

A Web application on WebLogic Server includes the following files:

- At least one servlet or JSP, along with any helper classes.
- Optionally, a `web.xml` deployment descriptor, a Java EE standard XML document that describes the contents of a WAR file.
- Optionally, a `weblogic.xml` deployment descriptor, an XML document containing WebLogic Server-specific elements for Web applications.
- A Web application can also include HTML and XML pages with supporting files such as images and multimedia files.

1.4.1 Servlets

Servlets are Java classes that execute in WebLogic Server, accept a request from a client, process it, and optionally return a response to the client. An `HttpServlet` is most often used to generate dynamic Web pages in response to Web browser requests.

1.4.2 JavaServer Pages

JavaServer Pages (JSPs) are Web pages coded with an extended HTML that makes it possible to embed Java code in a Web page. JSPs can call custom Java classes, known as tag libraries, using HTML-like tags. The `appc` compiler compiles JSPs and translates them into servlets. WebLogic Server automatically compiles JSPs if the servlet class file is not present or is older than the JSP source file. See [Section 5.2, "Building Modules and Applications Using `wlappc`"](#).

You can also precompile JSPs and package the servlet class in a Web application (WAR) file to avoid compiling in the server. Servlets and JSPs may require additional helper classes that must also be deployed with the Web application.

1.4.3 More Information on Web Application Modules

See the following documentation:

- [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#).
- *Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server*

- *Developing JSP Tag Extensions for Oracle WebLogic Server*

1.5 Enterprise JavaBean Modules

Enterprise JavaBeans (EJB) technology is the server-side component architecture for the development and deployment of component-based business applications. EJB technology enables rapid and simplified development of distributed, transactional, secure, and portable applications based on Java EE 7 technology.

The EJB 3.2 specification (JSR 345) provides simplified programming and packaging model changes. The mandatory use of Java interfaces from previous versions has been removed, allowing plain old Java objects to be annotated and used as EJB components. The simplification is further enhanced through the ability to place EJB modules directly inside of Web applications, removing the need to produce archives to store the Web and EJB components and combine them together in an EAR file.

1.5.1 EJB Documentation in WebLogic Server

For more information about using EJBs with WebLogic Server, see:

- For information about all the new EJB features, see "New Features and Changes in EJBs" in *Understanding Oracle WebLogic Server*.
- For information about basic EJB concepts and components, see "Enterprise Java Beans (EJBs)" in *Developing Enterprise JavaBeans for Oracle WebLogic Server*.
- For instructions on how to program, package, and deploy 3.x EJBs on WebLogic Server, see *Developing Enterprise JavaBeans for Oracle WebLogic Server*.
- For instructions on how to organize and build WebLogic Server EJBs in a split directory environment, see *Developing Applications for Oracle WebLogic Server*.
- For more information on how to program and package 2.x EJBs, see *Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server*.

1.5.2 Additional EJB Information

To learn more about EJB concepts, such as the benefits of enterprise beans, the types of enterprise beans, and their life cycles, then visit the following Web sites:

- Enterprise JavaBeans 3.2 Specification (JSR-345) at <http://jcp.org/en/jsr/summary?id=345>
- The "Enterprise Beans" chapter of the Java EE 7 Tutorial at <http://docs.oracle.com/javaee/7/tutorial/partentbeans.htm#BNBLR>
- Introducing the Java EE 6 Platform: Part 3 (EJB Technology, Even Easier to Use) at <http://www.oracle.com/technetwork/articles/javaee/javaee6overview-part3-139660.html#ejbeasy>

1.6 Connector Modules

Connectors (also known as resource adapters) contain the Java, and if necessary, the native modules required to interact with an Enterprise Information System (EIS). A resource adapter deployed to the WebLogic Server environment enables Java EE applications to access a remote EIS. WebLogic Server application developers can use HTTP servlets, JavaServer Pages (JSPs), Enterprise JavaBeans (EJBs), and other APIs to develop integrated applications that use the EIS data and business logic.

To deploy a resource adapter to WebLogic Server, you must first create and configure WebLogic Server-specific deployment descriptor, `weblogic-ra.xml` file, and add this to the deployment directory. Resource adapters can be deployed to WebLogic Server as standalone modules or as part of an enterprise application. See [Section 1.7, "Enterprise Applications"](#).

For more information on connectors, see *Developing Resource Adapters for Oracle WebLogic Server*.

1.7 Enterprise Applications

An enterprise application consists of one or more Web application modules, EJB modules, and resource adapters. It might also include a client application. An enterprise application can be optionally defined by an `application.xml` file, which was the standard Java EE deployment descriptor for enterprise applications.

1.7.1 Java EE Programming Model

An important aspect of the Java EE programming model is the introduction of metadata annotations. Annotations simplify the application development process by allowing a developer to specify within the Java class itself how the application behaves in the container, requests for dependency injection, and so on. Annotations are an alternative to deployment descriptors that were required by older versions of enterprise applications (1.4 and earlier).

With Java EE annotations, the standard `application.xml` and `web.xml` deployment descriptors are optional. The Java EE programming model uses the JDK annotations feature (see <http://docs.oracle.com/javaee/7/api/>) for Web containers, such as EJBs, servlets, Web applications, and JSPs. See [Chapter 8, "Using Java EE Annotations and Dependency Injection."](#)

If the application includes WebLogic Server-specific extensions, the application is further defined by a `weblogic-application.xml` file. Enterprise applications that include a client module will also have a `client-application.xml` deployment descriptor and a WebLogic run-time client application deployment descriptor. See [Appendix A, "Enterprise Application Deployment Descriptor Elements."](#)

1.7.2 Packaging and Deployment Overview

For both production and development purposes, Oracle recommends that you package and deploy even standalone Web applications, EJBs, and resource adapters as part of an enterprise application. Doing so allows you to take advantage of Oracle's split development directory structure, which greatly facilitates application development. See [Chapter 4, "Creating a Split Development Directory Environment."](#)

An enterprise application consists of Web application modules, EJB modules, and resource adapters. It can be packaged as follows:

- For development purposes, Oracle recommends the WebLogic split development directory structure. Rather than having a single archived EAR file or an exploded EAR directory structure, the split development directory has two parallel directories that separate source files and output files. This directory structure is optimized for development on a single WebLogic Server instance. See [Chapter 4, "Creating a Split Development Directory Environment."](#) Oracle provides the `wlpackage` Ant task, which allows you to create an EAR without having to use the JAR utility; this is exclusively for the split development directory structure. See [Section 6.2, "Packaging Applications Using `wlpackage`."](#)

- For development purposes, Oracle further recommends that you package standalone Web applications and Enterprise JavaBeans (EJBs) as part of an enterprise application, so that you can take advantage of the split development directory structure. See [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#).
- For production purposes, Oracle recommends the exploded (unarchived) directory format. This format enables you to update files without having to redeploy the application. To update an archived file, you must unarchive the file, update it, then rearchive and redeploy it.
- You can choose to package your application as a JAR archived file using the `jar` utility with an `.ear` extension. Archived files are easier to distribute and take up less space. An EAR file contains all of the JAR, WAR, and RAR module archive files for an application and an XML descriptor that describes the bundled modules. See [Section 6.2, "Packaging Applications Using `wlpackage`"](#).

The optional `META-INF/application.xml` deployment descriptor contains an element for each Web application, EJB, and connector module, as well as additional elements to describe security roles and application resources such as databases. If this descriptor is present the WebLogic deployer picks the list of modules from this descriptor. However if this descriptor is not present, the container guesses the modules from the annotations defined on the POJO (plain-old-Java-object) classes. See [Appendix A, "Enterprise Application Deployment Descriptor Elements."](#)

1.8 WebLogic Web Services

Web services can be shared by and used as modules of distributed Web-based applications. They commonly interface with existing back-end applications, such as customer relationship management systems, order-processing systems, and so on. Web services can reside on different computers and can be implemented by vastly different technologies, but they are packaged and transported using standard Web protocols, such as HTTP, thus making them easily accessible by any user on the Web.

A Web service consists of the following modules, at a minimum:

- A Web service implementation hosted by a server on the Web. WebLogic Web services are hosted by WebLogic Server. A Web service module may include either Java classes or EJBs that implement the Web service. Web services are packaged either as Web application archives (WARs) or EJB modules (JARs), depending on the implementation.
- A standard for transmitting data and Web service invocation calls between the Web service and the user of the Web service. WebLogic Web services use Simple Object Access Protocol (SOAP) 1.1 as the message format and HTTP as the connection protocol.
- A standard for describing the Web service to clients so they can invoke it. WebLogic Web services use Web services Description Language (WSDL) 1.1, an XML-based specification, to describe themselves.
- A standard for clients to invoke Web services—JAX-WS or JAX-RPC. See *Developing JAX-WS Web Services for Oracle WebLogic Server* or *Developing JAX-RPC Web Services for Oracle WebLogic Server*, respectively.
- A standard for finding and registering the Web service (UDDI).

For more information about WebLogic Web services and the standards that are supported, see *Understanding WebLogic Web Services for Oracle WebLogic Server*.

1.9 JMS and JDBC Modules

JMS and JDBC configurations are stored as modules, defined by an XML file that conforms to the `weblogic-jms.xsd` and `jdbc-data-source.xsd` schema, respectively. These modules are similar to standard Java EE modules. An administrator can create and manage JMS and JDBC modules as global system resources, as modules packaged with a Java EE application (as a packaged resource), or as standalone modules that can be made globally available.

With modular deployment of JMS and JDBC resources, you can migrate your application and the required JMS or JDBC configuration from environment to environment, such as from a testing environment to a production environment, without opening an enterprise application file (such as an EAR file) or a JMS or JDBC standalone module, and without extensive manual JMS or JDBC reconfiguration.

Application developers create application modules in an enterprise-level IDE or another development tool that supports editing of XML files, then package the JMS or JDBC modules with an application and pass the application to a WebLogic administrator to deploy.

For more information, see:

- "Configuring JMS Application Modules for Deployment"
- "Configuring JDBC Application Modules for Deployment"

1.10 WebLogic Diagnostic Framework Modules

The WebLogic Diagnostic Framework (WLDF) provides features for generating, gathering, analyzing, and persisting diagnostic data from WebLogic Server instances and from applications deployed to server instances. For server-scoped diagnostics, some WLDF features are configured as part of the configuration for the domain. Other features are configured as system resource descriptors that can be targeted to servers (or clusters). For application-scoped diagnostics, diagnostic features are configured as resource descriptors for the application.

Application-scoped instrumentation is configured and deployed as a diagnostic module, which is similar to a diagnostic system module. However, an application module is configured in an XML configuration file named `weblogic-diagnostics.xml` which is packaged with the application archive.

For detailed instructions for configuring instrumentation for applications, see "Configuring Application-Scoped Instrumentation".

1.10.1 Using an External Diagnostics Descriptor

WebLogic Server also supports the use of an external diagnostics descriptor so you can integrate diagnostic functionality into an application that has not imported diagnostic descriptors. This feature supports the deployment view and deployment of an application or a module, detecting the presence of an external diagnostics descriptor if the descriptor is defined in your deployment plan (`plan.xml`).

1.10.1.1 Defining an External Diagnostics Descriptor

First, define the diagnostic descriptor as external and configure its URI in the `plan.xml` file. For example:

```
<module-override>
  <module-name>reviewService.ear</module-name>
  <module-type>ear</module-type>
```

```
</module-descriptor>
<module-descriptor external="true">
<root-element>wldf-resource</root-element>
<uri>META-INF/weblogic-diagnostics.xml</uri>
...
...
</module-override>
<config-root>D:\plan</config-root>
```

Then place the external diagnostic descriptor file under the URI. Using the example above, you would place the descriptor file under `d:\plan\META-INF`.

1.11 Coherence Grid Archive (GAR) Modules

A Coherence GAR module provides distributed in-memory caching and data grid computing that allows applications to increase their availability, scalability, and performance. GAR modules are deployed as both standalone modules and packaged with Java EE applications (as a packaged resource). A GAR module may also be made globally available.

A GAR module is defined by the `coherence-application.xml` deployment descriptor and must conform to the `coherence-application.xsd` XML schema. The GAR contains the artifacts that comprise a Coherence application: Coherence configuration files, application classes (such as entry processors, aggregators, filters), and any dependencies that are required.

1.12 Bean Validation

The Bean Validation 1.1 specification (JSR 349) defines a metadata model and API for validating data in JavaBeans components. It is supported on both the server and Java EE 7 client; therefore, instead of distributing validation of data over several layers, such as the browser and the server side, you can define the validation constraints in one place and share them across the different layers. Further, bean validation is not only for validating beans. In fact, it can also be used to validate any Java object.

Bean Validation and JNDI

Where required by the Java EE specifications, the default `Validator` and `ValidatorFactory` are located using JNDI under the names `java:comp/Validator` and `java:comp/ValidatorFactory`. These two artifacts reflect the validation descriptor that is in scope.

Bean Validation Configuration

Bean validation can be configured by using XML descriptors or annotation.

- Descriptors:
 - Descriptor elements override corresponding annotations.
 - Weblogic Server allows one descriptor per module. Therefore, an application can have several validation descriptors but only one is allowed per module scope.
 - Validation descriptors are named `validation.xml` and are packaged in the `META-INF` directory, except for Web modules, where the descriptor is packaged in the `WEB-INF` directory.
- Annotations:

- Injection of the default `Validator` and `ValidatorFactory` is requested using the `@Resource` annotation. However, not all source files are scanned for this annotation.
- The WebLogic Connector uses bean validation internally to validate the connector descriptors.

Once bean validation is configured, the standard set of container managed classes for a given container will be scanned. For example, for EJBs, bean and interceptor classes are scanned. Web application classes and `ManagedBeans` also support the injection of `Validator` and `ValidatorFactories`.

For more information about the classes that support bean validation, please see the related component specifications for the list of classes that support dependency injection.

1.13 XML Deployment Descriptors

A *deployment configuration* refers to the process of defining the deployment descriptor values required to deploy an enterprise application to a particular WebLogic Server domain. The deployment configuration for an application or module is stored in three types of XML document: Java EE deployment descriptors, WebLogic Server descriptors, and WebLogic Server deployment plans. This section describes the Java EE and WebLogic-specific deployment descriptors. See [Section 1.14, "Deployment Plans"](#) for information on deployment plans.

The Java EE programming model uses the JDK annotations feature for Web containers, such as EJBs, servlets, Web applications, and JSPs. Annotations simplify the application development process by allowing a developer to specify within the Java class itself how the component behaves in the container, requests for dependency injection, and so on. Annotations are an alternative to deployment descriptors that were required by older versions of Web applications (2.4 and earlier), enterprise applications (1.4 and earlier), and Enterprise JavaBeans (2.x and earlier). See [Chapter 8, "Using Java EE Annotations and Dependency Injection."](#)

However, enterprise applications fully support the use of deployment descriptors, even though the standard Java EE ones are not required. For example, you may prefer to use the old EJB 2.x programming model, or might want to allow further customizing of the EJB at a later development or deployment stage; in these cases you can create the standard deployment descriptors in addition to, or instead of, the metadata annotations.

Modules and applications have deployment descriptors—XML documents—that describe the contents of the directory or JAR file. Deployment descriptors are text documents formatted with XML tags. The Java EE specifications define standard, portable deployment descriptors for Java EE modules and applications. Oracle defines additional WebLogic-specific deployment descriptors for deploying a module or application in the WebLogic Server environment.

[Table 1–1](#) lists the types of modules and applications and their Java EE-standard and WebLogic-specific deployment descriptors.

Note: The XML schemas for the WebLogic deployment descriptors listed in the following table include elements from the <http://xmlns.oracle.com/weblogic/weblogic-javaee/1.7/weblogic-javaee.xsd> schema, which describes common elements shared among all WebLogic-specific deployment descriptors.

For the most current schema information, see: <http://www.oracle.com/technetwork/middleware/weblogic/overview/index.html>.

Table 1–1 Java EE and WebLogic Deployment Descriptors

Module or Application	Scope	Deployment Descriptors
Web Application	Java EE	<p>web.xml</p> <p>See the Servlet 3.0 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/web-app_3_1.xsd</p> <p>WEB-INF/beans.xml—required only if the classes in the WAR file are to participate in Contexts and Dependency Injection (CDI)</p> <p>Schema: http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/beans_1_1.xsd</p> <p>See Chapter 9, "Using Contexts and Dependency Injection for the Java EE Platform."</p>
	WebLogic	<p>weblogic.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-web-app/1.8/weblogic-web-app.xsd</p> <p>See "weblogic.xml Deployment Descriptor Elements" in <i>Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server</i>.</p>
Enterprise Bean 3.0	Java EE	<p>ejb-jar.xml</p> <p>See the EJB 3.2 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/ejb-jar_3_2.xsd</p> <p>META-INF/beans.xml—required only if the classes in the EJB JAR file are to participate in CDI</p> <p>Schema: http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/beans_1_1.xsd</p> <p>See Chapter 9, "Using Contexts and Dependency Injection for the Java EE Platform."</p>

Table 1–1 (Cont.) Java EE and WebLogic Deployment Descriptors

Module or Application	Scope	Deployment Descriptors
	WebLogic	<p>weblogic-ejb-jar.xml</p> <p>Schema http://xmlns.oracle.com/weblogic/weblogic-ejb-jar/1.6/weblogic-ejb-jar.xsd</p> <p>weblogic-rdbms-jar.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-rdbms-jar/1.2/weblogic-rdbms-jar.xsd</p> <p>persistence-configuration.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/persistence-configuration/1.0/persistence-configuration.xsd</p> <p>See <i>Developing Enterprise JavaBeans for Oracle WebLogic Server</i>.</p>
Enterprise Bean 2.1	Java EE	<p>ejb-jar.xml</p> <p>See the EJB 2.1 Schema at http://java.sun.com/xml/ns/j2ee/ejb-jar_2_1.xsd</p>
	WebLogic	<p>weblogic-ejb-jar.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-ejb-jar/1.6/weblogic-ejb-jar.xsd</p> <p>See "The weblogic-ejb-jar.xml Deployment Descriptor" in <i>Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server</i>.</p> <p>weblogic-cmp-rdbms-jar.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-rdbms-jar/1.2/weblogic-rdbms-jar.xsd</p> <p>See "The weblogic-cmp-rdbms-jar.xml Deployment Descriptor" in <i>Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server</i>.</p>
Web services	Java EE	<p>webservices.xml</p> <p>See the Web services 1.4 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/javaee_web_services_1_4.xsd</p>

Table 1–1 (Cont.) Java EE and WebLogic Deployment Descriptors

Module or Application	Scope	Deployment Descriptors
	WebLogic	<p>weblogic-webservices.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-webservices/1.1/weblogic-webservices.xsd</p> <p>weblogic-wsee-clientHandlerChain.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-wsee-clientHandlerChain/1.0/weblogic-wsee-clientHandlerChain.xsd</p> <p>weblogic-webservices-policy.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/webservice-policy-ref/1.1/web-service-policy-ref.xsd</p> <p>weblogic-wsee-standaloneclient.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-wsee-standaloneclient/1.0/weblogic-wsee-standaloneclient.xsd</p> <p>See "WebLogic Web Service Deployment Descriptor Element Reference" in <i>WebLogic Web Services Reference for Oracle WebLogic Server</i>.</p>
Resource Adapter	Java EE	<p>ra.xml</p> <p>See the Connector 1.7 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/connector_1_7.xsd</p> <p>META-INF/beans.xml—required only if the classes in the RAR file are to participate in CDI</p> <p>Schema: http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/beans_1_1.xsd</p> <p>See Chapter 9, "Using Contexts and Dependency Injection for the Java EE Platform."</p>
	WebLogic	<p>weblogic-ra.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-connector/1.5/weblogic-connector.xsd</p> <p>See "weblogic-ra.xml Schema" in <i>Developing Resource Adapters for Oracle WebLogic Server</i>.</p>
Enterprise Application	Java EE	<p>application.xml</p> <p>See the Application 7 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/application_7.xsd</p>
	WebLogic	<p>weblogic-application.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-application/1.7/weblogic-application.xsd</p> <p>See Section A.1, "weblogic-application.xml Deployment Descriptor Elements".</p>

Table 1–1 (Cont.) Java EE and WebLogic Deployment Descriptors

Module or Application	Scope	Deployment Descriptors
Client Application	Java EE	<p>application-client.xml</p> <p>See the Application Client 7 Schema at http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/application-client_7.xsd</p> <p>META-INF/beans.xml—required only if the classes in the application client JAR file are to participate in CDI</p> <p>Schema: http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/beans_1_1.xsd</p> <p>See Chapter 9, "Using Contexts and Dependency Injection for the Java EE Platform."</p>
	WebLogic	<p>application-client.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-application-client/1.4/weblogic-application-client.xsd</p> <p>See "Developing a Java EE Application Client (Thin Client)" in <i>Developing Stand-alone Clients for Oracle WebLogic Server</i>.</p>
HTTP Pub/Sub Application	WebLogic	<p>weblogic-pubsub.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-pubsub/1.0/weblogic-pubsub.xsd</p> <p>See "Using the HTTP Publish-Subscribe Server" in <i>Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server</i>.</p>
JMS Module	WebLogic	<p><i>FileName-jms.xml</i>, where <i>FileName</i> can be anything you want.</p> <p>Schema: http://xmlns.oracle.com/weblogic/weblogic-jms/1.4/weblogic-jms.xsd</p> <p>See "Configuring JMS Application Modules for Deployment" in <i>Administering JMS Resources for Oracle WebLogic Server</i>.</p>
JDBC Module	WebLogic	<p><i>FileName-jdbc.xml</i>, where <i>FileName</i> can be anything you want.</p> <p>Schema: http://xmlns.oracle.com/weblogic/jdbc-data-source/1.5/jdbc-data-source.xsd</p> <p>See "Configuring JDBC Application Modules for Deployment" in <i>Administering JDBC Data Sources for Oracle WebLogic Server</i>.</p>
Deployment Plan	WebLogic	<p>plan.xml</p> <p>Schema: http://xmlns.oracle.com/weblogic/deployment-plan/1.1/deployment-plan.xsd</p> <p>See "Understanding WebLogic Server Deployment" in <i>Deploying Applications to Oracle WebLogic Server</i>.</p>

Table 1–1 (Cont.) Java EE and WebLogic Deployment Descriptors

Module or Application	Scope	Deployment Descriptors
Resource Deployment Plan	WebLogic	resource-deployment-plan.xml Schema: http://xmlns.oracle.com/weblogic/resource-deployment-plan/1.0/resource-deployment-plan.xsd See "Using Resource Deployment Plans" in <i>Using WebLogic Server MT</i> .
WLDF Module	WebLogic	weblogic-diagnostics.xml Schema: http://xmlns.oracle.com/weblogic/weblogic-diagnostics/1.0/weblogic-diagnostics.xsd See "Deploying WLDF Application Modules" in <i>Configuring and Using the Diagnostics Framework for Oracle WebLogic Server</i> .
Coherence Modules	WebLogic	coherence-application.xml Schema: http://xmlns.oracle.com/coherence/coherence-application/1.0/coherence-application.xsd See <i>Developing Oracle Coherence Applications for Oracle WebLogic Server</i> .

When you package a module or application, you create a directory to hold the deployment descriptors—WEB-INF or META-INF—and then create the XML deployment descriptors in that directory.

1.13.1 Automatically Generating Deployment Descriptors

WebLogic Server provides a variety of tools for automatically generating deployment descriptors. These are discussed in the sections that follow.

1.13.2 EJBGen

EJBGen is an Enterprise JavaBeans 2.x code generator or command-line tool that uses Javadoc markup to generate EJB deployment descriptor files. You annotate your Bean class file with Javadoc tags and then use EJBGen to generate the Remote and Home classes and the deployment descriptor files for an EJB application, reducing to a single file you need to edit and maintain your EJB .java and descriptor files. See "EJBGen Reference" in *Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server*.

1.13.3 Java-based Command-line Utilities

WebLogic Server includes a set of Java-based command-line utilities that automatically generate both standard Java EE and WebLogic-specific deployment descriptors for Web applications and enterprise applications.

These command-line utilities examine the classes you have assembled in a staging directory and build the appropriate deployment descriptors based on the servlet classes, and so on. These utilities include:

- `java weblogic.marathon.ddinit.EarInit` — automatically generates the deployment descriptors for enterprise applications.
- `java weblogic.marathon.ddinit.WebInit` — automatically generates the deployment descriptors for Web applications.

For an example of DDInit, assume that you have created a directory called `c:\stage` that contains the JSP files and other objects that make up a Web application but you have not yet created the `web.xml` and `weblogic.xml` deployment descriptors. To automatically generate them, execute the following command:

```
prompt> java weblogic.marathon.ddinit.WebInit c:\stage
```

The utility generates the `web.xml` and `weblogic.xml` deployment descriptors and places them in the `WEB-INF` directory, which DDInit will create if it does not already exist.

1.13.4 Upgrading Deployment Descriptors From Previous Releases of Java EE and WebLogic Server

So that your applications can take advantage of the features in the current Java EE specification and release of WebLogic Server, Oracle recommends that you always upgrade deployment descriptors when you migrate applications to a new release of WebLogic Server.

To upgrade the deployment descriptors in your Java EE applications and modules, first use the `weblogic.DDConverter` tool to generate the upgraded descriptors into a temporary directory. Once you have inspected the upgraded deployment descriptors to ensure that they are correct, repackage your Java EE module archive or exploded directory with the new deployment descriptor files.

Invoke `weblogic.DDConverter` with the following command:

```
prompt> java weblogic.DDConverter [options] archive_file_or_directory
```

where *archive_file_or_directory* refers to the archive file (EAR, WAR, JAR, or RAR) or exploded directory of your enterprise application, Web application, EJB, or resource adapter.

The following table describes the `weblogic.DDConverter` command options.

Option	Description
<code>-d <dir></code>	Specifies the directory to which descriptors are written.
<code>-help</code>	Prints the standard usage message.
<code>-quiet</code>	Turns off output messages except error messages.
<code>-verbose</code>	Turns on additional output used for debugging.

The following example shows how to use the `weblogic.DDConverter` command to generate upgraded deployment descriptors for the `my.ear` enterprise application into the subdirectory `tempdir` in the current directory:

```
prompt> java weblogic.DDConverter -d tempdir my.ear
```

1.14 Deployment Plans

A *deployment plan* is an XML document that defines an application's WebLogic Server deployment configuration for a specific WebLogic Server environment. A deployment plan resides outside of an application's archive file, and can apply changes to deployment properties stored in the application's existing WebLogic Server deployment descriptors. Administrators use deployment plans to easily change an application's WebLogic Server configuration for a specific environment *without* modifying existing Java EE or WebLogic-specific deployment descriptors. Multiple

deployment plans can be used to reconfigure a single application for deployment to multiple, differing WebLogic Server environments.

After programmers have finished programming an application, they export its deployment configuration to create a custom deployment plan that administrators later use for deploying the application into new WebLogic Server environments. Programmers distribute both the application deployment files and the custom deployment plan to deployers (for example, testing, staging, or production administrators) who use the deployment plan as a blueprint for configuring the application for their environment.

WebLogic Server provides the following tools to help programmers export an application's deployment configuration:

- `weblogic.PlanGenerator` creates a template deployment plan with null variables for selected categories of WebLogic Server deployment descriptors. This tool is recommended if you are beginning the export process and you want to create a template deployment plan with null variables for an entire class of deployment descriptors.
- The WebLogic Server Administration Console updates or creates new deployment plans as necessary when you change configuration properties for an installed application. You can use the WebLogic Server Administration Console to generate a new deployment plan or to add or override variables in an existing plan. The WebLogic Server Administration Console provides greater flexibility than `weblogic.PlanGenerator`, because it allows you to interactively add or edit individual deployment descriptor properties in the plan, rather than export entire categories of descriptor properties.

For complete and detailed information about creating and using deployment plans, see:

- "Understanding WebLogic Server Deployment"
- "Exporting an Application for Deployment to New Environments"
- "Understanding WebLogic Server Deployment Plans"

1.15 Development Tools

This section describes required and optional tools for developing WebLogic Server applications.

1.15.1 Java API Reference and the `wls-api.jar` File

Oracle provides the Oracle Fusion Middleware Java API Reference for Oracle WebLogic Server, which defines all of the supported Java classes available for use when developing Java EE applications for WebLogic Server. See the *Java API Reference for Oracle WebLogic Server*.

In conjunction with the Java API Reference for Oracle WebLogic Server, Oracle recommends using the `wls-api.jar` file to develop and compile Java EE applications for your WebLogic Server environment. The `wls-api.jar` file is located in the `wlserver/server/lib` directory of your WebLogic Server distribution and offers the following benefits:

- developing more performant code based on tested best practices
- avoiding deprecated or unsupported code paths

1.15.1.1 Using the wls-api.jar File

Use the `wls-api.jar` file and the `api.jar` file to develop and compile your Java EE applications in Integrated Development Environments (IDEs), such as Oracle JDeveloper. IDEs provide an array of tools to simplify development of Java-based applications. The `wls-api.jar` file provides a clean and concise API jar to develop and run Java EE applications for WebLogic environments.

Note: The `wls-api.jar` file does not reference any Java EE classes. Oracle provides the `api.jar` file with a manifest classpath that includes access to Java EE JARs.

You may need to include the `weblogic.jar` file in the classpath of your development environment to access tools such as WLST, the `weblogic.Deployer` utility, and `weblogic.appc`.

1.15.1.2 Using the weblogic.jar File

You must continue to use the `weblogic.jar` file for runtime environments, as a client or to develop and compile legacy applications. However, use the `wls-api.jar` file to develop and compile Java EE applications for your WebLogic Server environment.

1.15.2 Apache Ant

The preferred Oracle method for building applications with WebLogic Server is Apache Ant. Ant is a Java-based build tool. One of the benefits of Ant is that it is extended with Java classes, rather than shell-based commands. Oracle provides numerous Ant extension classes to help you compile, build, deploy, and package applications using the WebLogic Server split development directory environment.

Another benefit is that Ant is a cross-platform tool. Developers write Ant build scripts in eXtensible Markup Language (XML). XML tags define the targets to build, dependencies among targets, and tasks to execute in order to build the targets. Ant libraries are bundled with WebLogic Server to make it easier for our customers to build Java applications out of the box.

To use Ant, you must first set your environment by executing either the `setExamplesEnv.cmd` (Windows) or `setExamplesEnv.sh` (UNIX) commands located in the `WL_SERVER\samples\domains\wl_server` directory, where `WL_SERVER` is your WebLogic Server installation directory.

For a complete explanation of ant capabilities, see:

<http://jakarta.apache.org/ant/manual/index.html>

Note: The Apache Jakarta Web site publishes online documentation for only the most current version of Ant, which might be different from the version of Ant that is bundled with WebLogic Server. Use the following command, after setting your WebLogic environment, to determine the version of Ant bundled with WebLogic Server:

```
prompt> ant -version
```

To view the documentation for a specific version of Ant, such as the version included with WebLogic Server, download the Ant zip file from <http://archive.apache.org/dist/ant/binaries/> and extract the documentation.

For more information on using Ant to compile your cross-platform scripts or using cross-platform scripts to create XML scripts that can be processed by Ant, refer to any of the WebLogic Server examples, such as `ORACLE_HOME/wlserver/samples/server/examples/src/examples/ejb20/basic/beanManaged/build.xml`, where `ORACLE_HOME` represents the directory in which you installed WebLogic Server. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

Also refer to the following WebLogic Server documentation on building examples using Ant: `ORACLE_HOME/wlserver/samples/server/examples/src/examples/examples.html`.

1.15.2.1 Using a Third-Party Version of Ant

You can use your own version of Ant if the one bundled with WebLogic Server is not adequate for your purposes. To determine the version of Ant that is bundled with WebLogic Server, run the following command after setting your WebLogic environment:

```
prompt> ant -version
```

If you plan to use a different version of Ant, you can replace the appropriate JAR file in the `WL_HOME\server\lib\ant` directory with an updated version of the file (where `WL_HOME` refers to the main WebLogic installation directory, such as `c:\Oracle\Middleware\Oracle_Home\wlserver`) or add the new file to the front of your CLASSPATH.

1.15.2.2 Changing the Ant Heap Size

By default the environment script allocates a heap size of 128 megabytes to Ant. You can increase or decrease this value for your own projects by setting the `-X` option in your local `ANT_OPTS` environment variable. For example:

```
prompt> setenv ANT_OPTS=-Xmx128m
```

If you want to set the heap size permanently, add or update the `MEM_ARGS` variable in the scripts that set your environment, start WebLogic Server, and so on, as shown in the following snippet from a Windows command script that starts a WebLogic Server instance:

```
set MEM_ARGS=-Xms32m -Xmx200m
```

See the scripts and commands in `WL_HOME/server/bin` for examples of using the `MEM_ARGS` variable.

1.15.3 Source Code Editor or IDE

You need a text editor to edit Java source files, configuration files, HTML or XML pages, and JavaServer Pages. An editor that gracefully handles Windows and UNIX line-ending differences is preferred, but there are no other special requirements for your editor. You can edit HTML or XML pages and JavaServer Pages with a plain text editor, or use a Web page editor such as Dreamweaver. For XML pages, you can also use an enterprise-level IDE with DTD validation or another development tool that supports editing of XML files.

1.15.4 Database System and JDBC Driver

Nearly all WebLogic Server applications require a database system. You can use any DBMS that you can access with a standard JDBC driver, but services such as WebLogic

Java Message Service (JMS) require a supported JDBC driver for Oracle, Sybase, Informix, Microsoft SQL Server, or IBM DB2. See the Oracle Fusion Middleware Supported System Configurations page on Oracle Technology Network to find out about supported database systems and JDBC drivers.

1.15.5 Web Browser

Most Java EE applications are designed to be executed by Web browser clients. WebLogic Server supports the HTTP 1.1 specification and is tested with current versions of the Firefox and Microsoft Internet Explorer browsers.

When you write requirements for your application, note which Web browser versions you will support. In your test plans, include testing plans for each supported version. Be explicit about version numbers and browser configurations. Will your application support Secure Socket Layers (SSL) protocol? Test alternative security settings in the browser so that you can tell your users what choices you support.

If your application uses applets, it is especially important to test browser configurations you want to support because of differences in the JVMs embedded in various browsers. One solution is to require users to install the Java plug-in so that everyone has the same Java run-time version.

1.15.6 Third-Party Software

You can use third-party software products to enhance your WebLogic Server development environment. See "WebLogic Developer Tools Resources" at <http://www.oracle.com/technology/products/developer-tools/index.html>, which provides developer tools information for products that support the application servers.

Note: Check with the software vendor to verify software compatibility with your platform and WebLogic Server version.

1.16 New and Changed Features in this Release

This release of WebLogic Server introduces the following new application development features:

- Monitoring support for WebSockets—You can monitor message statistics and runtime properties for WebSocket applications and endpoints. For more information, see [Section 18.14, "Monitoring WebSocket Applications."](#)
- WebLogic Server now supports version 1.1 of the Java API for WebSockets.
- Maven support updates, including the following:
 - WebLogic Server now supports Maven version 3.2.5.
 - The Install goal now supports the quickstart installers.
 - Beginning in version 12.2.1, there is a single unified version of WLST that automatically includes the WLST environment from all products in the ORACLE_HOME. If you use the wlst-client goal to run WLST scripts that contain Fusion Middleware dependencies, you must first include the FMWSHARE dependency to pull in the necessary libraries needed by those scripts.
 - The source parameter of the deploy, redeploy, and distribute-app goals now supports using a Maven coordinate, HTTP URL, or a local file/directory to specify the application to deploy.

For more information about the updated Maven support, see [Chapter 3, "Using the WebLogic Maven Plug-In."](#)

- Class caching with the policy classloader—The policy classloader is the default system class loader when starting WebLogic Server using a `startWebLogic` script. The policy classloader improves class loader performance and server startup time through class caching and indexing and is supported in any WebLogic mode (development or production). For more information, see [Section 11.1.5, "Class Caching With the Policy Classloader."](#)

For a comprehensive listing of the new WebLogic Server features introduced in this release, see *What's New in Oracle WebLogic Server 12.2.1*.

Using Ant Tasks to Configure and Use a WebLogic Server Domain

This chapter describes how to start and stop WebLogic Server instances and configure WebLogic Server domains using WebLogic Ant tasks in your development build scripts.

This chapter includes the following sections:

- [Section 2.1, "Overview of Configuring and Starting Domains Using Ant Tasks"](#)
- [Section 2.2, "Starting Servers and Creating Domains Using the wlservlet Ant Task"](#)
- [Section 2.3, "Configuring a WebLogic Server Domain Using the wlconfig Ant Task"](#)
- [Section 2.4, "Using the libclasspath Ant Task"](#)

2.1 Overview of Configuring and Starting Domains Using Ant Tasks

WebLogic Server provides a pair of Ant tasks to help you perform common configuration tasks in a development environment. The configuration tasks enable you to start and stop WebLogic Server instances as well as create and configure WebLogic Server domains.

When combined with other WebLogic Ant tasks, you can create powerful build scripts for demonstrating or testing your application with custom domains. For example, a single Ant build script can:

- Compile your application using the `wlcompile`, `wlappc`, and Web services Ant tasks.
- Create a new single-server domain and start the Administration Server using the `wlservlet` Ant task.
- Configure the new domain with required application resources using the `wlconfig` Ant task.
- Deploy the application using the `wldeploy` Ant task.
- Automatically start a compiled client application to demonstrate or test product features.

The sections that follow describe how to use the configuration Ant tasks, `wlservlet` and `wlconfig`.

2.2 Starting Servers and Creating Domains Using the wlservlet Ant Task

The `wlservlet` Ant task enables you to start, reboot, shutdown, or connect to a WebLogic Server instance. The server instance may already exist in a configured WebLogic Server domain, or you can create a new single-server domain for development by using the `generateconfig=true` attribute.

When you use the `wlservlet` task in an Ant script, the task does not return control until the specified server is available and listening for connections. If you start up a server instance using `wlservlet`, the server process automatically terminates after the Ant VM terminates. If you only connect to a currently-running server using the `wlservlet` task, the server process keeps running after Ant completes.

The `wlservlet` WebLogic Server Ant task extends the standard `java` Ant task (`org.apache.tools.ant.taskdefs.Java`). This means that all the attributes of the `java` Ant task also apply to the `wlservlet` Ant task. For example, you can use the `output` and `error` attributes to specify the name of the files to which output and standard errors of the `wlservlet` Ant task is written, respectively. For full documentation about the attributes of the standard Java Ant task, see Java on the Apache Ant site (<http://ant.apache.org/manual/Tasks/java.html>).

2.2.1 Basic Steps for Using wlservlet

To use the `wlservlet` Ant task:

1. Set your environment.

On Windows, execute the `setWLSEnv.cmd` command, located in the directory `WL_HOME\server\bin`, where `WL_HOME` is the top-level directory of your WebLogic Server installation.

On UNIX, execute the `setWLSEnv.sh` command, located in the directory `WL_HOME\server\bin`, where `WL_HOME` is the top-level directory of your WebLogic Server installation.

Note: The `wlservlet` task is predefined in the version of Ant shipped with WebLogic Server. If you want to use the task with your own Ant installation, add the following task definition in your build file:

```
<taskdef name="wlservlet"
classname="weblogic.ant.taskdefs.management.WLServer"/>
```

Note: On UNIX operating systems, the `setWLSEnv.sh` command does not set the environment variables in all command shells. Oracle recommends that you execute this command using the Korn shell or bash shell.

2. Add a call to the `wlservlet` task in the build script to start, shutdown, restart, or connect to a server. See [Section 2.2.3, "wlservlet Ant Task Reference"](#) for information about `wlservlet` attributes and default behavior.
3. Execute the Ant task or tasks specified in the `build.xml` file by typing `ant` in the staging directory, optionally passing the command a target argument:

```
prompt> ant
```

Use `ant -verbose` to obtain more detailed messages from the `wlservlet` task.

2.2.2 Sample build.xml Files for wlsver

The following shows a minimal `wlsver` target that starts a server in the current directory using all default values:

```
<target name="wlsver-default">
  <wlsver/>
</target>
```

This target connects to an existing, running server using the indicated connection parameters and user name/password combination:

```
<target name="connect-server">
  <wlsver host="127.0.0.1" port="7001" username="weblogic" password="weblogic"
  action="connect"/>
</target>
```

This target starts a WebLogic Server instance configured in the `config` subdirectory:

```
<target name="start-server">
  <wlsver dir="./config" host="127.0.0.1" port="7001" action="start"/>
</target>
```

This target creates a new single-server domain in an empty directory, and starts the domain's server instance:

```
<target name="new-server">
  <delete dir="./tmp"/>
  <mkdir dir="./tmp"/>
  <wlsver dir="./tmp" host="127.0.0.1" port="7001"
  generateConfig="true" username="weblogic" password="weblogic" action="start"/>
</target>
```

2.2.3 wlsver Ant Task Reference

The following table describes the attributes of the `wlsver` Ant task.

Table 2–1 Attributes of the wlsver Ant Task

Attribute	Description	Data Type	Required?
<code>policy</code>	The path to the security policy file for the WebLogic Server domain. This attribute is used only for starting server instances.	File	No
<code>dir</code>	The path that holds the domain configuration (for example, <code>c:\Oracle\Middleware\user_projects\domains\mydomain</code>). By default, <code>wlsver</code> uses the current directory.	File	No
<code>beahome</code>	The path to the Middleware Home directory (for example, <code>c:\Oracle\Middleware</code>).	File	No
<code>weblogichome</code>	The path to the WebLogic Server installation directory (for example, <code>c:\Oracle\Middleware\wlsver_12.1</code>).	File	No
<code>servername</code>	The name of the server to start, shutdown, reboot, or connect to. A WebLogic Server instance is uniquely identified by its protocol, host, and port values, so if you use this set of attributes to specify the server you want to start, shutdown or reboot, you do not need to specify its actual name using the <code>servername</code> attribute. The only exception is when you want to shutdown the Administration server; in this case you <i>must</i> specify this attribute. The default value for this attribute is <code>myserver</code> .	String	Required only when shutting down the Administration server.

Table 2–1 (Cont.) Attributes of the wlsserver Ant Task

Attribute	Description	Data Type	Required?
domainname	The name of the WebLogic Server domain in which the server is configured.	String	No
adminserverurl	The URL to access the Administration Server in the domain. This attribute is required if you are starting up a Managed Server in the domain.	String	Required for starting Managed Servers.
username	The user name of an administrator account. If you omit both the <code>username</code> and <code>password</code> attributes, <code>wlsserver</code> attempts to obtain the encrypted user name and password values from the <code>boot.properties</code> file. See "Boot Identity Files" in the <i>Administering Server Startup and Shutdown for Oracle WebLogic Server</i> for more information on <code>boot.properties</code> .	String	No
password	The password of an administrator account. If you omit both the <code>username</code> and <code>password</code> attributes, <code>wlsserver</code> attempts to obtain the encrypted user name and password values from the <code>boot.properties</code> file. See "Boot Identity Files" in the <i>Administering Server Startup and Shutdown for Oracle WebLogic Server</i> for more information on <code>boot.properties</code> .	String	No
pkpassword	The private key password for decrypting the SSL private key file.	String	No
timeout	The maximum time, in milliseconds, that <code>wlsserver</code> waits for a server to boot. This also specifies the maximum amount of time to wait when connecting to a running server. The default value for this attribute is 0, which means that the Ant task will wait indefinitely until the server transitions to the <code>RUNNING</code> state.	long	No
timeoutSeconds	The maximum time, in seconds, that <code>wlsserver</code> waits for a server to boot. This also specifies the maximum amount of time to wait when connecting to a running server. The default value for this attribute is 0, which means that the Ant task will wait indefinitely until the server transitions to the <code>RUNNING</code> state.	long	No
productionmodeenabled	Specifies whether a server instance boots in development mode or in production mode. Development mode enables a WebLogic Server instance to automatically deploy and update applications that are in the <code>domain_name/autodeploy</code> directory (where <code>domain_name</code> is the name of a WebLogic Server domain). In other words, development mode lets you use auto-deploy. Production mode disables the auto-deployment feature. See "Deploying Applications and Modules" for more information. Valid values for this attribute are <code>True</code> and <code>False</code> . The default value is <code>False</code> (which means that by default a server instance boots in development mode.) Note: If you boot the server in production mode by setting this attribute to <code>True</code> , you must reboot the server to set the mode back to development mode. Or in other words, you cannot reset the mode on a running server using other administrative tools, such as the WebLogic Server Scripting Tool (WLST).	Boolean	No
host	The DNS name or IP address on which the server instance is listening. The default value for this attribute is <code>localhost</code> .	String	No

Table 2–1 (Cont.) Attributes of the wlsserver Ant Task

Attribute	Description	Data Type	Required?
port	The TCP port number on which the server instance is listening. The default value for this attribute is 7001.	int	No
generateconfig	Specifies whether or not wlsserver creates a new domain for the specified server. Valid values for this attribute are true and false. The default value is false.	Boolean	No
action	Specifies the action wlsserver performs: start, shutdown, reboot, or connect. The shutdown action can be used with the optional forceshutdown attribute perform a forced shutdown. The default value for this attribute is start.	String	No
failonerror	This is a global attribute used by WebLogic Server Ant tasks. It specifies whether the task should fail if it encounters an error during the build. Valid values for this attribute are true and false. The default value is false.	Boolean	No
forceshutdown	This optional attribute is used in conjunction with the action="shutdown" attribute to perform a forced shutdown. For example: <pre><wlsserver host="\${wls.host}" port="\${port}" username="\${wls.username}" password="\${wls.password}" action="shutdown" forceshutdown="true"/></pre> Valid values for this attribute are true and false. The default value is false.	Boolean	No
noExit	(Optional) Leave the server process running after Ant exits. Valid values are true or false. The default value is false, which means the server process will shut down when Ant exits.	Boolean	No
protocol	Specifies the protocol that the wlsserver Ant task uses to communicate with the WebLogic Server instance. Valid values are t3, t3s, http, https, and iiop. The default value is t3.	String	No
forceImplicitUpgrade	Specifies whether the wlsserver Ant task, if run against an 8.1 (or previous) domain, should implicitly upgrade it. Valid values are true or false. The default value is false, which means that the Ant task does <i>not</i> implicitly upgrade the domain, but rather, will fail with an error indicating that the domain needs to be upgraded. For more information about upgrading domains, see <i>Upgrading Oracle WebLogic Server</i> .	Boolean	No

Table 2–1 (Cont.) Attributes of the wlserver Ant Task

Attribute	Description	Data Type	Required?
configFile	<p>Specifies the configuration file for your domain.</p> <p>The value of this attribute must be a valid XML file that conforms to the XML schema as defined in the WebLogic Server Domain Configuration Schema at http://xmlns.oracle.com/weblogic/domain/1.0/domain.xsd.</p> <p>The XML file must exist in the Administration Server's root directory, which is either the current directory or the directory that you specify with the <code>dir</code> attribute.</p> <p>If you do not specify this attribute, the default value is <code>config.xml</code> in the directory specified by the <code>dir</code> attribute. If you do not specify the <code>dir</code> attribute, then the default domain directory is the current directory.</p>	String	No.
useBootProperties	<p>Specifies whether to use the <code>boot.properties</code> file when starting a WebLogic Server instance. If this attribute is set to <code>true</code>, WebLogic Server uses the user name and encrypted password stored in the <code>boot.properties</code> file to start rather than any values set with the <code>username</code> and <code>password</code> attributes.</p> <p>Note: The values of the <code>username</code> and <code>password</code> attributes are still used when shutting down or rebooting the WebLogic Server instance. The <code>useBootProperties</code> attribute applies <i>only</i> when starting the server. Valid values for this attribute are <code>true</code> and <code>false</code>. The default value is <code>false</code>.</p>	Boolean	No
verbose	<p>Specifies that the Ant task output additional information as it is performing its action.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. The default value is <code>false</code>.</p>	Boolean	No

2.3 Configuring a WebLogic Server Domain Using the wlconfig Ant Task

The following sections describe how to use the `wlconfig` Ant task to configure a WebLogic Server domain.

Note: For equivalent functionality, you should use the WebLogic Scripting Tool (WLST). See *Understanding the WebLogic Scripting Tool*.

2.3.1 What the wlconfig Ant Task Does

The `wlconfig` Ant task enables you to configure a WebLogic Server domain by creating, querying, or modifying configuration MBeans on a running Administration Server instance. Specifically, `wlconfig` enables you to:

- Create new MBeans, optionally storing the new MBean Object Names in Ant properties.
- Set attribute values on a named MBean available on the Administration Server.
- Create MBeans and set their attributes in one step by nesting `set` attribute commands within `create` MBean commands.
- Query MBeans, optionally storing the query results in an Ant property reference.
- Query MBeans and set attribute values on all matching results.

- Establish a parent/child relationship among MBeans by nesting create commands within other create commands.

2.3.2 Basic Steps for Using wlconfig

1. Set your environment in a command shell. See [Section 2.2.1, "Basic Steps for Using wlsrver"](#) for details.

Note: The `wlconfig` task is predefined in the version of Ant shipped with WebLogic Server. If you want to use the task with your own Ant installation, add the following task definition in your build file:

```
<taskdef name="wlconfig"
classname="weblogic.ant.taskdefs.management.WLConfig"/>
```

2. `wlconfig` is commonly used in combination with `wlsrver` to configure a new WebLogic Server domain created in the context of an Ant task. If you will be using `wlconfig` to configure such a domain, first use `wlsrver` attributes to create a new domain and start the WebLogic Server instance.
3. Add an initial call to the `wlconfig` task to connect to the Administration Server for a domain. For example:

```
<target name="doconfig">
  <wlconfig url="t3://localhost:7001" username="weblogic"
    password=password>
</target>
```

4. Add nested `create`, `delete`, `get`, `set`, and `query` elements to configure the domain.
5. Execute the Ant task or tasks specified in the `build.xml` file by typing `ant` in the staging directory, optionally passing the command a target argument:

```
prompt> ant doconfig
```

Use `ant -verbose` to obtain more detailed messages from the `wlconfig` task.

Note: Since WLST is the recommended tool for domain creation scripts, you should refer to the WLST offline sample scripts that are installed with the software. The offline scripts demonstrate how to create domains using the domain templates and are located in the following directory: `WL_HOME\common\templates\scripts\wlst`, where `WL_HOME` refers to the top-level installation directory for WebLogic Server. For example, the `basicWLSDomain.py` script creates a simple WebLogic domain, while `sampleMedRecDomain.py` creates a domain that defines resources similar to those used in the Avitek MedRec sample. See *Understanding the WebLogic Scripting Tool*.

2.3.3 wlconfig Ant Task Reference

The following sections describe the attributes and elements that can be used with `wlconfig`.

2.3.4 Main Attributes

The following table describes the main attributes of the `wlconfig` Ant task.

Table 2–2 Main Attributes of the wlconfig Ant Task

Attribute	Description	Data Type	Required?
url	The URL of the domain's Administration Server.	String	Yes
username	The user name of an administrator account.	String	No
password	<p>The password of an administrator account.</p> <p>To avoid having the plain text password appear in the build file or in process utilities such as <code>ps</code>, first store a valid user name and encrypted password in a configuration file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command. Then omit both the <code>username</code> and <code>password</code> attributes in your Ant build file. When the attributes are omitted, <code>wlconfig</code> attempts to login using values obtained from the default configuration file.</p> <p>If you want to obtain a user name and password from a non-default configuration file and key file, use the <code>userconfigfile</code> and <code>userkeyfile</code> attributes with <code>wlconfig</code>.</p> <p>See the command reference for <code>storeUserConfig</code> in the <i>WLST Command Reference for WebLogic Server</i> for more information on storing and encrypting passwords.</p>	String	No
failonerror	This is a global attribute used by WebLogic Server Ant tasks. It specifies whether the task should fail if it encounters an error during the build. This attribute is set to true by default.	Boolean	No
userconfigfile	<p>Specifies the location of a user configuration file to use for obtaining the administrative user name and password. Use this option, instead of the <code>username</code> and <code>password</code> attributes, in your build file when you do not want to have the plain text password shown in-line or in process-level utilities such as <code>ps</code>.</p> <p>Before specifying the <code>userconfigfile</code> attribute, you must first generate the file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command as described in the <i>WLST Command Reference for WebLogic Server</i>.</p>	File	No
userkeyfile	<p>Specifies the location of a user key file to use for encrypting and decrypting the user name and password information stored in a user configuration file (the <code>userconfigfile</code> attribute).</p> <p>Before specifying the <code>userkeyfile</code> attribute, you must first generate the key file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command as described in the <i>WLST Command Reference for WebLogic Server</i>.</p>	File	No

2.3.5 Nested Elements

`wlconfig` also has several elements that can be nested to specify configuration options:

- [create](#)
- [delete](#)
- [set](#)
- [get](#)
- [query](#)
- [invoke](#)

2.3.5.1 create

The `create` element creates a new MBean in the WebLogic Server domain. The `wlconfig` task can have any number of `create` elements.

A `create` element can have any number of nested `set` elements, which set attributes on the newly-created MBean. A `create` element may also have additional, nested `create` elements that create child MBeans.

The `create` element has the following attributes.

Table 2–3 Attributes of the create Element

Attribute	Description	Data Type	Required?
<code>name</code>	The name of the new MBean object to create.	String	No (<code>wlconfig</code> supplies a default name if none is specified.)
<code>type</code>	The MBean type.	String	Yes
<code>property</code>	The name of an optional Ant property that holds the object name of the newly-created MBean. Note: If you nest a <code>create</code> element inside of another <code>create</code> element, you cannot specify the <code>property</code> attribute for the <i>nested</i> <code>create</code> element.	String	No

2.3.5.2 delete

The `delete` element removes an existing MBean from the WebLogic Server domain. `delete` takes a single attribute:

Table 2–4 Attribute of the delete Element

Attribute	Description	Data Type	Required?
<code>mbean</code>	The object name of the MBean to delete.	String	Required when the <code>delete</code> element is a direct child of the <code>wlconfig</code> task. Not required when nested within a <code>query</code> element.

2.3.5.3 set

The `set` element sets MBean attributes on a named MBean, a newly-created MBean, or on MBeans retrieved as part of a query. You can include the `set` element as a direct child of the `wlconfig` task, or nested within a `create` or `query` element.

The `set` element has the following attributes:

Table 2–5 Attributes of the set Element

Attribute	Description	Data Type	Required?
attribute	The name of the MBean attribute to set.	String	Yes
value	The value to set for the specified MBean attribute. You can specify multiple object names (stored in Ant properties) as a value by delimiting the entire value list with quotes and separating the object names with a semicolon.	String	Yes
mbean	The object name of the MBean whose values are being set. This attribute is required only when the set element is included as a direct child of the main wlconfig task; it is not required when the set element is nested within the context of a create or query element.	String	Required only when the set element is a direct child of the wlconfig task.
domain	This attribute specifies the JMX domain name for Security MBeans and third-party SPI MBeans. It is not required for administration MBeans, as the domain corresponds to the WebLogic Server domain. Note: You cannot use this attribute if the set element is nested inside of a create element.	String	No

2.3.5.4 get

The `get` element retrieves attribute values from an MBean in the WebLogic Server domain. The `wlconfig` task can have any number of `get` elements.

The `get` element has the following attributes.

Table 2–6 Attributes of the get Element

Attribute	Description	Data Type	Required?
attribute	The name of the MBean attribute whose value you want to retrieve.	String	Yes
property	The name of an Ant property that will hold the retrieved MBean attribute value.	String	Yes
mbean	The object name of the MBean you want to retrieve attribute values from.	String	Yes

2.3.5.5 query

The `query` elements finds MBean that match a search pattern.

The `query` element supports the following nested child elements:

- `set`—performs set operations on all MBeans in the result set.
- `get`—performs get operations on all MBeans in the result set.
- `create`—each MBean in the result set is used as a parent of a new MBean.
- `delete`—performs delete operations on all MBeans in the result set.
- `invoke`—invokes all matching MBeans in the result set.

`wlconfig` can have any number of nested `query` elements.

`query` has the following attributes:

Table 2–7 Attributes of the query Element

Attribute	Description	Data Type	Required?
domain	The name of the WebLogic Server domain in which to search for MBeans.	String	No
type	The type of MBean to query.	String	No
name	The name of the MBean to query.	String	No
pattern	A JMX query pattern.	String	No
property	The name of an optional Ant property that will store the query results.	String	No
domain	This attribute specifies the JMX domain name for Security MBeans and third-party SPI MBeans. It is not required for administration MBeans, as the domain corresponds to the WebLogic Server domain.	String	No

2.3.5.6 invoke

The `invoke` element invokes a management operation for one or more MBeans. For WebLogic Server MBeans, you usually use this command to invoke operations other than the `getAttribute` and `setAttribute` that most WebLogic Server MBeans provide.

The `invoke` element has the following attributes.

Table 2–8 Attributes of the invoke Element

Attribute	Description	Data Type	Required?
mbean	The object name of the MBean you want to invoke.	String	You must specify either the <code>mbean</code> or <code>type</code> attribute of the <code>invoke</code> element.
type	The type of MBean to invoke.	String	You must specify either the <code>mbean</code> or <code>type</code> attribute of the <code>invoke</code> element.
methodName	The method of the MBean to invoke.	String	Yes
arguments	The list of arguments (separated by spaces) to pass to the method specified by the <code>methodName</code> attribute.	String	No

2.3.6 Example of Creating a Security Realm with the wlconfig Ant Task

The following example demonstrates how to create a security realm with the `wlconfig` Ant task:

Example 2–1 Creating a Security Realm with wlconfig

```
<wlconfig url="t3://myhost:7001"
  username="weblogic"
  password="password">
  <create type="weblogic.management.security.Realm" name="MyRealm"
property="new.provider">
    <set attribute="DefaultRealm" value="false"/>
    <create name="MyAuthenticator"
type="weblogic.security.providers.authentication.DefaultAuthenticator"
realm="MyRealm"/>
    <create name="MyAuthorizer"
type="weblogic.security.providers.authorization.DefaultAuthorizer"
realm="MyRealm"/>
  </create>
</wlconfig>
```

```

        <create name="MyRoleMapper"
type="weblogic.security.providers.authorization.DefaultRoleMapper"
realm="MyRealm"/>
        <create name="MyCredentialMapper"
type="weblogic.security.providers.credentials.DefaultCredentialMapper"
realm="MyRealm"/>
        <create name="MyCertPathProvider"
type="weblogic.security.providers.pk.WebLogicCertPathProvider" realm="MyRealm"/>
    </create>
    <set mbean="Security:Name=MyRealm" attribute="CertPathBuilder"
value="Security:Name=MyRealmMyCertPathProvider"/>
</wlconfig>

```

2.4 Using the libclasspath Ant Task

Use the `libclasspath` Ant task to build applications that use libraries, such as application libraries and Web libraries.

- [Section 2.4.1, "libclasspath Task Definition"](#)
- [Section 2.2.3, "wlservlet Ant Task Reference"](#)
- [Section 2.4.5, "Example libclasspath Ant Task"](#)

2.4.1 libclasspath Task Definition

To use the task with your own Ant installation, add the following task definition in your build file:

```

<taskdef name="libclasspath"
classname="weblogic.ant.taskdefs.build.LibClasspathTask"/>

```

2.4.2 libclasspath Ant Task Reference

The following sections describe the attributes and elements that can be used with the `libclasspath` Ant task.

- [Section 2.4.3, "Main libclasspath Attributes"](#)
- [Section 2.4.4, "Nested libclasspath Elements"](#)

2.4.3 Main libclasspath Attributes

The following table describes the main attributes of the `libclasspath` Ant task.

Table 2–9 *Attributes of the libclasspath Ant Task*

Attribute	Description	Required
<code>basedir</code>	The root of <code>.ear</code> or <code>.war</code> file to extract from.	Either <code>basedir</code> or <code>basewar</code> is required.
<code>basewar</code>	The name of the <code>.war</code> file to extract from.	If <code>basewar</code> is specified, <code>basedir</code> is ignored and the library referenced in <code>basewar</code> is used as the <code>.war</code> file to extract classpath or resourcepath information from.

Table 2–9 (Cont.) Attributes of the libclasspath Ant Task

Attribute	Description	Required
tmpdir	The fully qualified name of the directory to be used for extracting libraries.	Yes.
classpathproperty	<p>Contains the classpath for the referenced libraries. For example, if basedir points to a .war file that references Web application libraries in the weblogic.xml file, the classpathproperty contains the WEB-INF/classes and WEB-INF/lib directories of the Web application libraries.</p> <p>Additionally, if basedir points to a .war file that has .war files under WEB-INF/boa-ext, the classpathproperty contains the WEB-INF/classes and WEB-INF/lib directories for the Oracle extensions.</p>	At least one of the two attributes is required.
resourcepathproperty	<p>Contains library resources that are not classes. For example, if basedir points to a .war file that has .war files under WEB-INF/boa-ext, resourcepathproperty contains the roots of the exploded extensions.</p>	

2.4.4 Nested libclasspath Elements

libclasspath also has two elements that can be nested to specify configuration options. At least one of the elements is required when using the libclasspath Ant task:

2.4.4.1 librarydir

The following attribute is required when using this element:

dir—Specifies that all files in this directory are registered as available libraries.

2.4.4.2 library

The following attribute is required when using this element:

file—Register this file as an available library.

2.4.5 Example libclasspath Ant Task

This section provides example code of a libclasspath Ant task:

Example 2–2 Example libclasspath Ant Task Code

```

.
.
.
<taskdef name="libclasspath"
classname="weblogic.ant.taskdefs.build.LibClasspathTask"/>

<!-- Builds classpath based on libraries defined in weblogic-application.xml.
-->
<target name="init.app.libs">
  <libclasspath basedir="${src.dir}" tmpdir="${tmp.dir}"
classpathproperty="app.lib.classpath">
    <librarydir dir="${weblogic.home}/common/deployable-libraries"/>
  </libclasspath>
  <echo message="app.lib.classpath is ${app.lib.classpath}" level="info"/>

```

```
    </target>  
    .  
    .  
    .
```

Using the WebLogic Maven Plug-In

Apache Maven is a software tool for building and managing Java-based projects. WebLogic Server provides support for Maven through the provisioning of plug-ins that enable you to perform various operations on WebLogic Server from within a Maven environment.

The `weblogic-maven-plugin` provides enhanced functionality to install, start and stop servers, create domains, execute WLST scripts, and compile and deploy applications. With the `weblogic-maven-plugin`, you can install WebLogic Server from within your Maven environment to fulfill the local WebLogic Server requirement when needed.

The following sections describe using `weblogic-maven-plugin`:

- [Section 3.1, "Installing Maven"](#)
- [Section 3.2, "Configuring the WebLogic Maven Plug-In"](#)
- [Section 3.3, "Maven Plug-In Goals"](#)

See *Developing Applications Using Continuous Integration* for additional Maven documentation. In particular, see the section "Building Java EE Projects for WebLogic Server with Maven."

3.1 Installing Maven

Before you can use the `weblogic-maven-plugin` plug-in, you must first have a functional Maven installation and a Maven repository. WebLogic Server supports Maven 3.0.4 and later.

A distribution of Maven 3.2.5 is included with WebLogic Server in the following location: `ORACLE_HOME\oracle_common\modules\org.apache.maven_3.2.5`. This is a copy of the standard Maven 3.2.5 release, without any modifications.

Run the `ORACLE_HOME\wlserver\server\bin\setWLSEnv` script to configure Maven.

Alternatively, you can download and install your own copy of Maven from the Maven Web site: <http://maven.apache.org>. Make sure you set any required variables as detailed in that documentation, such as `M2_HOME` and `JAVA_HOME`.

Note: The `weblogic-maven-plugin` sets the Java protocol handler to `weblogic.net`. To use the default JDK protocol handlers, specify the system property `-DUseSunHttpHandler=true` in the JVM that executes Maven. To do this, override the environment variable `MAVEN_OPTS` inside the `mvn.bat` or `mvn.sh` files to set the appropriate value. For example: `set MAVEN_OPTS="-DUseSunHttpHandler=true"`.

For detailed information on installing and using Maven to build applications and projects, see the Maven Users Centre at <http://maven.apache.org/users/index.html>.

3.2 Configuring the WebLogic Maven Plug-In

The `weblogic-maven-plugin` plug-in is provided as a pre-built JAR file and accompanying pom file.

Follow these steps for installing and configuring `weblogic-maven-plugin`:

1. Install the Oracle Maven sync plug-in and run the push goal:
 - a. Change directory to `ORACLE_HOME\oracle_common\plugins\maven\com\oracle\maven\oracle-maven-sync\12.2.1`.
 - b. `mvn install:install-file -DpomFile=oracle-maven-sync-12.2.1.pom -Dfile=oracle-maven-sync-12.2.1.jar`.
 - c. `mvn com.oracle.maven:oracle-maven-sync:push -DoracleHome=c:\oracle\middleware\oracle_home\`.
2. You can validate whether you have successfully installed the plug-in using the Maven `help:describe` goal. See the Apache help plug-in describe goal documentation for additional information.

```
mvn help:describe -DgroupId=com.oracle.weblogic
-DartifactId=weblogic-maven-plugin -Dversion=12.2.1-0-0
```

3.2.1 How to use the WebLogic Maven Plug-in

There are two ways to invoke the goals in the WebLogic Maven plug-in:

- From a Maven project POM.
- From the command line.

The `appc`, `wsgen`, `wsimport`, `ws-jwsc`, `ws-wsdlc`, and `ws-clientgen` goals require a POM.

Other goals will work either way. For example, `install`, `wlst`, `wlst-client`, `start-server`, or `stop-server` work either from a POM or the command line.

The preferred and recommended way is to use a Maven POM file.

To invoke a WebLogic Maven plug-in goal from a POM file, do the following:

1. Add a build section to your POM if you do not already have one.
2. Add a plug-in section to the build section for the WebLogic Maven plug-in.
3. Add an execution section to the WebLogic Maven plug-in's `plugin` section for each goal that you want to execute. This section must provide the necessary parameters for the goal, and map the goal to a phase in the Maven Lifecycle.

Example 3-1 shows an example of the necessary additions, including a few goals. The detailed descriptions of each goal later in this section present the details for parameters and examples for each goal.

If you map multiple goals to the same lifecycle phase, they are typically executed in the order you list them in the POM.

Example 3-1 Modifying the POM File

```

<build>
  <plugins>
    <plugin>
      <!-- This is the configuration for the
           weblogic-maven-plugin
      -->
      <groupId>com.oracle.weblogic</groupId>
    <artifactId>weblogic-maven-plugin</artifactId>
      <version>12.2.1-0-0</version>
      <configuration>
        <middlewareHome>/fmwhome/wls12210</middlewareHome>
      </configuration>
    <executions>
      <!-- Execute the appc goal during the package phase -->
      <execution>
        <id>wls-appc</id>
        <phase>package</phase>
        <goals>
          <goal>appc</goal>
        </goals>
        <configuration>
          <source>${project.build.directory}/${project.name}.${project.packaging}</source>
        </configuration>
      </execution>
      <!-- Deploy the application to the WebLogic Server in the
           pre-integration-test phase
      -->
      <execution>
        <id>wls-deploy</id>
        <phase>pre-integration-test</phase>
        <goals>
          <goal>deploy</goal>
        </goals>
        <configuration>
          <!--The admin URL where the app is deployed.
           Here use the plugin's default value t3://localhost:7001-->
          <adminurl>t3://127.0.0.1:7001</adminurl>
          <user>weblogic</user>
          <password>password</password>
          <!--The location of the file or directory to be deployed-->
          <source>${project.build.directory}/${project.build.finalName}.${project.packaging}
        </source>
          <!--The target servers where the application is deployed.
           Here use the plugin's default value AdminServer-->
          <targets>AdminServer</targets>
          <verbose>true</verbose>
          <name>${project.build.finalName}</name>
        </configuration>
      </execution>
      <!-- Stop the application in the pre-integration-test phase -->
      <execution>
        <id>wls-stop-app</id>
        <phase>pre-integration-test</phase>
        <goals>
          <goal>stop-app</goal>
        </goals>
        <configuration>
          <adminurl>t3://127.0.0.1:7001</adminurl>
          <user>weblogic</user>

```

```

        <password>password</password>
</name>${project.build.finalName}</name>
    </configuration>
</execution>
</executions>
</plugin>
</plugins>
</build>

```

Table 3–1 lists the phases in the default Maven lifecycle.

Table 3–1 Maven Lifecycle Phases

Phase	Description
validate	Validates the project is correct and all necessary information is available.
compile	Compiles the source code of the project.
test	Tests the compiled source code using a suitable unit testing framework. These tests should not require the code be packaged or deployed.
package	Takes the compiled code and package it in its distributable format, such as a JAR.
integration-test	Processes and deploys the package if necessary into an environment where integration tests can be run.
verify	Runs any checks to verify the package is valid and meets quality criteria.
install	Installs the package into the local repository, for use as a dependency in other projects locally.
deploy	In an integration or release environment, copies the final package to the remote repository for sharing with other developers and projects.

Table 3–2 shows the most common mappings of goals to phases

Table 3–2 Common Mapping of Goals to Phases

Phase	Goal
validate	ws-clientgen, ws-wsdlc
compile	ws-jwsc
test	NA
package	appc
pre-integration-test ¹	install, create-domain, start-server, distribute-app, deploy, purge-tasks, redeploy, update-app, start-app, stop-app, wlst-client, and list-apps
post-integration-test ²	remove-domain, undeploy, stop-server, uninstall
verify	NA
install	NA
deploy	NA

¹ The integration-test phase has pre sub-phases that are executed before the actual execution of any integration tests, respectively.

² The integration-test phase has post sub-phases that are executed after the actual execution of any integration tests, respectively.

3.2.2 Basic Configuration POM File

[Example 3-2](#) illustrates a basic Java EE 6 Web application pom.xml file that demonstrates the use of the weblogic-maven-plugin appc goal.

Example 3-2 Basic Configuration pom.xml File

```
<project xmlns="http://maven.apache.org/POM/4.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0
  http://maven.apache.org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>demo.sab</groupId>
  <artifactId>maven-demo</artifactId>
  <version>1.0-SNAPSHOT</version>
  <packaging>war</packaging>

  <name>maven-demo</name>

  <properties>
    <endorsed.dir>${project.build.directory}/endorsed</endorsed.dir>
    <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
  </properties>

  <dependencies>
    <dependency>
      <groupId>com.oracle.weblogic</groupId>

3.3 Maven Plug-In Goals

[Table 3–3](#) lists all the `weblogic-maven-plugin` goals. Each goal is described in detail in the sections that follow.

Table 3–3 *Maven Plug-In Goals*

Goal Name	Description
appc	Generates and compiles the classes needed to deploy EJBs and JSPs to WebLogic Server. Also validates the deployment descriptors for compliance with the current specifications at both the individual module level and the application level.
create-domain	Creates a domain for WebLogic Server using a domain template. This goal supports specifying the domain directory (the last directory determines the domain name) and the administrative username and password. For more complex domain creation, use the <code>wlst</code> goal.
deploy	Deploys WebLogic Server applications and modules. Supports all deployment formats; for example, WAR, JAR, and such.
distribute-app	Prepares deployment files for deployment by copying deployment files to target servers and validating them.
install	Installs WebLogic Server.
list-apps	Lists the deployment names for applications and standalone modules deployed, distributed, or installed in the domain.
purge-tasks	Flushes out retired deployment tasks.
redploy	Redeploys a running application or part of a running application.
remove-domain	Removes a domain directory.
start-app	Starts an application deployed on WebLogic Server.
start-server	Starts WebLogic Server. This goal starts WLS by running a local start script. For starting remote servers using the node manager, use the <code>wlst</code> goal instead.
stop-app	Stops an application.
stop-server	Stops WebLogic Server. This goal stops WLS by running a local start script. For stopping remote servers using the node manager, use the <code>wlst</code> goal instead.
undeploy	Undeploys the application from WebLogic Server. Stops the deployment unit and removes staged files from target servers.
uninstall	Uninstalls WebLogic Server.
update-app	Updates an application's deployment plan by redistributing the plan files and reconfiguring the application based on the new plan contents.
wlst	WLST wrapper for Maven.
wlst-client	WLST wrapper that does not require a local server install for WLST online commands.
ws-clientgen	Generates client Web service artifacts from a WSDL.

Table 3–3 (Cont.) Maven Plug-In Goals

Goal Name	Description
wsgen	JAX-WS service endpoint implementation class and generates all of the portable artifacts for a JAX-WS Web service.
wsimport	Maven goal that parses a WSDL and binding files and generates the Java code needed to access it
ws-jwsc	Builds a JAX-WS Web service.
ws-wsdlc	Generates a set of artifacts and a partial Java implementation of the Web service from a WSDL.

3.3.1 appc

Full Name

`com.oracle.weblogic:weblogic-maven-plugin:appc`

Description

Generates and compiles the classes need to deploy EJBs and JSPs to WebLogic Server. Also validates the deployment descriptors for compliance with the current specifications at both the individual module level and the application level. Does not require a local server installation.

Parameters

Table 3–4 appc Parameters

Name	Type	Required	Description
<code>altappdd</code>	<code>java.lang.String</code>	false	Specifies an alternate descriptor. May be used to specify an alternate <code>application.xml</code> for an <code>.ear</code> deployment or an alternate <code>web.xml</code> or <code>ejb.xml</code> for standalone module deployments.
<code>altwlsappdd</code>	<code>java.lang.String</code>	false	Specifies the path to an alternative WebLogic Server application deployment descriptor.
<code>basicClientJar</code>	boolean	false	When true, does not include deployment descriptors in client JARs generated for EJBs. Default value is: <code>false</code>
<code>classpath</code>	<code>java.lang.String</code>	false	This parameter is deprecated in this release and ignored. Use the standard Maven dependency model instead to manipulate the effective CLASSPATH during a build.
<code>clientJarOutputDir</code>	<code>java.lang.String</code>	false	Specifies a directory where generated client JARs will be written.
<code>commentary</code>	boolean	false	This parameter is deprecated in this release.
<code>compiler</code>	<code>java.lang.String</code>	false	Specifies the Java compiler for compiling class files from the generated Java source code. The Java compiler program should be in your <code>PATH</code> unless you specify the absolute path to the compiler explicitly. Default value is: <code>javac</code>
<code>compilerClass</code>	<code>java.lang.String</code>	false	The class that invokes the compiler. Default value is: <code>com.sun.tools.javac.Main</code>
<code>continueCompilation</code>	boolean	false	When true, continues compilation even when there are errors in the JSP files. Default value is: <code>false</code>

Table 3–4 (Cont.) appc Parameters

Name	Type	Required	Description
debug	boolean	false	When true, compiles debugging information into class files. Default value is: false
deprecation	boolean	false	When true, warns about the use of deprecated methods in the generated Java source file when compiling the source file into a class file. Default value is: false
destdir	java.io.File	false	Specifies the directory where compiled class files are written. Use this parameter to place compiled classes in a directory that is already in your CLASSPATH.
enableHotCodeGen	boolean	false	This parameter is deprecated in this release.
forceGeneration	boolean	false	When true, forces the generation of EJB and JSP classes. Otherwise, the classes will not be regenerated if it is determined to be unnecessary. Default value is: false
idl	boolean	false	When true, generates IDL for EJB remote interfaces. Default value is: false
idlDirectory	java.lang.String	false	Specifies the directory where IDL files will be written. Default: the target directory or JAR
idlFactories	boolean	false	When true, generates factory methods for valuetypes. Default value is: false
idlMethodSignatures	java.lang.String	false	Specifies the method signatures used to trigger IDL code generation.
idlNoAbstractInterfaces	boolean	false	When true, does not generate abstract interfaces and methods or attributes that contain them. Default value is: false
idlNoValueTypes	boolean	false	Does not generate valuetypes or the methods and attributes that contain them. Default value is: false
idlOrbix	boolean	false	When true, generates IDL somewhat compatible with Orbix 2000 2.0 C++. Default value is: false
idlOverwrite	boolean	false	When true, overwrites existing IDL files. Default value is: false
idlVerbose	boolean	false	When true, displays additional status information for IDL generation. Default value is: false
idlVisibroker	boolean	false	When true, generates IDL somewhat compatible with Visibroker 4.5 C++. Default value is: false
ignorePlanValidation	boolean	false	When true, ignores the plan file if it does not exist.
iiop	boolean	false	When true, generates CORBA stubs for EJBs. Default value is: false
iiopDirectory	java.lang.String	false	Specifies the directory where IIOP stub files will be written. Default: the target directory or JAR
keepgenerated	boolean	false	When true, preserves the generated .java files. Default value is: false
libraries	java.lang.String	false	A comma-separated list of libraries.

Table 3–4 (Cont.) appc Parameters

Name	Type	Required	Description
librarydir	java.io.File	false	Registers all the files in the specified directory as libraries.
lineNumbers	boolean	false	When true, adds JSP line numbers to generated class files to aid in debugging. Default value is: false
manifest	java.io.File	false	This parameter is deprecated in this release. Use the standard Maven mechanism to specify the Manifest during packaging.
maxfiles	java.lang.Integer	false	Specifies the maximum number of generated Java files to be compiled at one time.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
noexit	boolean	false	When true, does not exit from the execution of the appc goal when encountering JSP compile errors. Default value is: true
normi	boolean	false	This parameter is deprecated in this release.
nowarn	boolean	false	When true, suppresses compiler warnings. Default value is: false
nowrite	boolean	false	This parameter is deprecated in this release.
optimize	boolean	false	When true, compiles with optimization on. Default value is: false
output	java.io.File	false	Specifies an alternate output archive or directory. When not set, the output is placed in the source archive or directory.
plan	java.io.File	false	Specifies the path to an optional deployment plan.
quiet	boolean	false	When true, turns off output except for errors.
runtimeFlags	java.lang.String	false	Passes a list of options to the compiler.
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored. Use the standard Maven dependency model instead to manipulate the effective CLASSPATH.
source	java.io.File	false	Specifies the path to the source files. Default value is: \${project.build.directory}/\${project.artifactId}.\${project.packaging}
sourceVersion	java.lang.String	false	Limits the compatibility of the Java files to a JDK no higher than specified. For example "1.5". The default value is the JDK version of the Java compiler used.
supressCompiler	boolean	false	This parameter is deprecated in this release and ignored. Use the standard Maven dependency model instead to add the target classes to the effective CLASSPATH during a build.
targetVersion	java.lang.String	false	Specifies the minimum level of the JVM required to run the compiled class files. For example, "1.5". The default value is the JDK version of the Java compiler used.
verbose	boolean	false	When true, displays additional status information during the compilation process. Default value is: false

Table 3–4 (Cont.) appc Parameters

Name	Type	Required	Description
verboseJavac	boolean	false	When true, enables verbose output from the Java compiler. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
writeInferredDescriptors	boolean	false	When true, writes out the descriptors with inferred information including annotations.

Usage Example

The `appc` goal executes the WebLogic Server application compiler utility to prepare an application for deployment.

```
<execution>
<id>wls-appc</id>
<phase>package</phase>
<goals>
<goal>appc</goal>
</goals>
<configuration>
<source>${project.build.directory}/${project.name}.${project.packaging}</source>
</configuration>
</execution>
```

[Example 3–3](#) shows typical `appc` goal output.

Example 3–3 appc

```
$ mvn com.oracle.weblogic:weblogic-maven-plugin:appc
-Dsource=target/basicWebapp.war -DforceGeneration=true

```

3.3.2 create-domain**Full Name**

com.oracle.weblogic:weblogic-maven-plugin:create-domain

Description

Creates a domain for WebLogic Server using a domain template. This goal supports specifying the domain directory (the last directory determines the domain name) and

the administrative username and password. This is a convenience goal for the simple use case. For more complex domain creation, use the `wlst` goal. If the domain is already created, `stdout` prints a status message but the goal does not fail.

Note: Beginning in version 12.2.1, there is a single unified version of WLST that automatically includes the WLST environment from all products in the `ORACLE_HOME`.

Parameters

Table 3–5 *create-domain Parameters*

Name	Type	Required	Description
<code>domainHome</code>	<code>java.lang.String</code>	<code>true</code>	Specifies the directory to use for creating the domain. This goal takes the name of the last subdirectory specified as the domain name and sets the new domain's name to that value. For example, <code>domainHome=/weblogic/domains/MyNewDomain</code> causes the domain name to be set to 'MyNewDomain'.
<code>domainTemplate</code>	<code>java.lang.String</code>	<code>false</code>	Specifies the domain template file to use to create the domain. The default domain template included with WebLogic Server is used when this parameter is not specified.
<code>failOnDomainExists</code>	<code>boolean</code>	<code>false</code>	When <code>true</code> and the domain to be created already exists, the build fails and an exception is thrown. When <code>false</code> and the domain to be created already exists, the build is successful and the existing domain is not overwritten. If the domain does not exist, this parameter has no effect. Default value is: <code>false</code>
<code>middlewareHome</code>	<code>java.lang.String</code>	<code>true</code>	The path to the Oracle Middleware install directory.
<code>password</code>	<code>java.lang.String</code>	<code>true</code>	Specifies the administrative password.
<code>serverClasspath</code>	<code>java.lang.String</code>	<code>false</code>	This parameter is deprecated and ignored in this release.
<code>user</code>	<code>java.lang.String</code>	<code>true</code>	Specifies the administrative user name.
<code>weblogicHome</code>	<code>java.lang.String</code>	<code>false</code>	This parameter is deprecated and ignored in this release.
<code>wlstVersion</code>	<code>java.lang.String</code>	<code>false</code>	Deprecated. As of version 12.2.1, there is a single, unified version of WLST. This parameter is deprecated and ignored.
<code>workingDir</code>	<code>java.lang.String</code>	<code>false</code>	The current working directory where the <code>create-domain</code> goal executes. The default value is: <code>\${project.build.directory}/weblogic-maven-plugin</code>

Usage Example

Use the `create-domain` goal to create a WebLogic Server domain from a specified WebLogic Server installation. You specify the location of the domain using the `domainHome` configuration parameter.

When creating a domain, a user name and password are required. You can specify these using the `user` and `password` configuration parameters in your POM file or by specifying them on the command line.

The domain name is taken from the last subdirectory specified in `domainHome`.

```

<execution>
<id>wls-create-domain</id>
<phase>pre-integration-test</phase>
<goals>
<goal>create-domain</goal>
</goals>
<configuration>
<middlewareHome>c:/dev/wls12210</middlewareHome>
<domainHome>${project.build.directory}/base_domain</domainHome>
<user>weblogic</user>
<password>password</password>
</configuration>
</execution>

```

Example 3-4 shows typical command output from the execution of the `create-domain` goal.

Example 3-4 *create-domain*

```

mvn com.oracle.weblogic:weblogic-maven-plugin:create-domain
-DdomainHome=c:\oracle\middleware\oracle_home\user_projects\domains\maven-domain
-DmiddlewareHome=c:\oracle\middleware\oracle_home -Duser=weblogic
-Dpassword=password

3.3.3 deploy

Full Name

com.oracle.weblogic:weblogic-maven-plugin:deploy

Description

Deploys WebLogic Server applications and modules to a running server. Supports all deployment formats; for example, WAR, JAR, RAR, and such. Does not require a local server installation.

Parameters

Table 3–6 *deploy Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
altappdd	java.lang.String	false	Specifies an alternate descriptor. May be used to specify an alternate application.xml for an .ear deployment or an alternate web.xml or ejb.xml for standalone module deployments.
appversion	java.lang.String	false	Version of the application to start.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
enableSecurityValidation	boolean	false	When true, enables validation of security data. Default value is: false
examples	boolean	false	When true, displays examples of how to use this plug-in.
external_stage	boolean	false	When true, indicates that the user wants to copy the application in the server staging area externally or using a third-party tool. When specified, WebLogic Server looks for the application under <code>StagingDirectoryName(of target server)/ applicationName</code> . Default value is: false
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.
libimplver	java.lang.String	false	Implementation version of a Java EE library or optional package. This option can be used only if the library or package does not include an implementation version in its manifest file.
library	boolean	false	Deploy as a shared Java EE library or optional package.

Table 3–6 (Cont.) deploy Parameters

Name	Type	Required	Description
libspeccver	java.lang.String	false	Specification version of a Java EE library or optional package. This option can be used only if the library or package does not include a specification version in its manifest file.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
nostage	boolean	false	When true, does not copy the deployment files to target servers, but leaves them in a fixed location, specified by the source parameter. By default, nostage is true for the Administration Server and stage is true for the Managed Server targets.
noversion	boolean	false	When true, ignores all version related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the -list action. Default value is: false
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group to which you want to deploy an application or library. For deploy and distribute operations, you must specify the name of the partition resource group to which you want to deploy or distribute applications or libraries by setting the resourceGroup attribute. If only one resource group exists in the specified partition, then the resourceGroup attribute is optional. The partition parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
plan	java.lang.String	false	Specifies the path to the deployment plan.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the source parameter specifies a path on the server, unless the upload parameter is also used. Default value is: false
resourceGroup	java.lang.String	false	Specifies the name of the resource group at the partition or domain level to which you want to deploy an application or library. For deploy and distribute operations, you must specify the name of the resource group to which you want to deploy or distribute applications or libraries by setting the resourceGroup attribute. For partitions, if only one resource group exists in the specified partition, then the resourceGroup attribute is optional. For other supported deployment actions, you do not specify the resourceGroup attribute, as WebLogic Server derives the resource group from the unique application name.
resourceGroupTemplate	java.lang.String	false	Specifies the name of the resource group template to which you want to deploy an application or library.

Table 3–6 (Cont.) deploy Parameters

Name	Type	Required	Description
retiretimeout	java.lang.Integer	false	Specifies the number of seconds before WebLogic Server undeploys the currently-running version of this application or module so that clients can start using a new version. When not specified, a graceful retirement policy is assumed. Default value is: -1
securityModel	java.lang.String	false	Specifies the security model to be used for this deployment, overriding the default security model for the security realm. Possible values are: DDOnly, CustomRoles, CustomRolesAndPolicies, and Advanced.
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
source	java.lang.String	false	Specifies the address of the artifact to deploy. The address can be one of the following: <ul style="list-style-type: none"> ■ A colon (:) separated list of Maven coordinates of the form: groupId:artifactId:packaging:classifier:version. ■ An archive file or exploded archive directory on the local system. For example, /home/myhome/myapps/helloworld.war. ■ A remote HTTP URL (http://foo/a/b.ear).
stage	boolean	false	When true, indicates that the application needs to be copied into the target server staging area before deployment. By default, nostage is true for the Administration Server and stage is true for the Managed Server targets.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: submod@mod-jms.xml@target or submoduleName@target.
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. The default is AdminServer.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of -1 means wait forever. Default value is: -1
upload	boolean	false	When true, copies the source files to the Administration Server's upload directory prior to deployment. Use this setting when running the plug-in remotely (using the remote parameter) and when the user lacks normal access to the Administration Server's file system. Default value is: false.
usenonexclusivelock	boolean	false	When true, the deployment operation uses an existing lock, already acquired by the same user, on the domain. This parameter is helpful in environments where multiple deployment tools are used simultaneously and one of the tools has already acquired a lock on the domain configuration. Default value is: false.
user	java.lang.String	false	Specifies the administrative user name.
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.

Table 3–6 (Cont.) deploy Parameters

Name	Type	Required	Description
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Usage Example

Use this goal to deploy an application.

```
<execution>
<id>wls-deploy</id>
<phase>pre-integration-test</phase>
<goals>
<goal>deploy</goal>
</goals>
<configuration>
<adminurl>t3://127.0.0.1:7001</adminurl>
<user>weblogic</user>
<password>password</password>
<source>${project.build.directory}/${project.build.finalName}
.${project.packaging}</source>
<targets>AdminServer</targets>
<verbose>true</verbose>
<name>${project.build.finalName}</name>
</configuration>
</execution>
```

[Example 3–5](#) shows typical deploy goal output.

Example 3–5 deploy

```

```

3.3.4 distribute-app

Full Name

com.oracle.weblogic:weblogic-maven-plugin:distribute-app

Description

Prepares deployment files for deployment by copying deployment files to target servers and validating them. Does not require a local server installation.

Parameters

Table 3-7 *distribute-app Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
enableSecurityValidation	boolean	false	When true, enables validation of security data. Default value is: false
examples	boolean	false	When true, displays examples of how to use this plug-in.
external_stage	boolean	false	When true, indicates that the user wants to copy the application in the server staging area externally or using a third-party tool. When specified, WebLogic Server looks for the application under StagingDirectoryName(of target server)/ applicationName. Default value is: false
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.

Table 3–7 (Cont.) distribute-app Parameters

Name	Type	Required	Description
nostage	boolean	false	When true, does not copy the deployment files to target servers, but leaves them in a fixed location, specified by the source parameter. By default, nostage is true for the Administration Server and stage is true for the Managed Server targets.
noversion	boolean	false	When true, ignores all version related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the -list action. Default value is: false
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to distribute an application or library. For deploy and distribute operations, you must specify the name of the partition resource group to which you want to deploy or distribute applications or libraries by setting the resourceGroup attribute. If only one resource group exists in the specified partition, then the resourceGroup attribute is optional. The partition parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
plan	java.lang.String	false	Specifies the path to the deployment plan.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the source parameter specifies a path on the server, unless the upload parameter is also used. Default value is: false
resourceGroup	java.lang.String	false	Specifies the name of the resource group at the partition or domain level on which you want to distribute an application or library. For deploy and distribute operations, you must specify the name of the resource group to which you want to deploy or distribute applications or libraries by setting the resourceGroup attribute. For partitions, if only one resource group exists in the specified partition, then the resourceGroup attribute is optional. For other supported deployment actions, you do not specify the resourceGroup attribute, as WebLogic Server derives the resource group from the unique application name.
resourceGroupTemplate	java.lang.String	false	Specifies the name of the resource group template on which you want to distribute an application or library.
retiretimeout	java.lang.Integer	false	Specifies the number of seconds before WebLogic Server undeploys the currently-running version of this application or module so that clients can start using a new version. When not specified, a graceful retirement policy is assumed. Default value is: -1
securityModel	java.lang.String	false	Specifies the security model to be used for this deployment, overriding the default security model for the security realm. Possible values are: DDOnly, CustomRoles, CustomRolesAndPolicies, and Advanced.

Table 3-7 (Cont.) distribute-app Parameters

Name	Type	Required	Description
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
source	java.lang.String	false	Specifies the address of the artifact to distribute. The address can be one of the following: <ul style="list-style-type: none"> ■ A colon (:) separated list of Maven coordinates of the form: groupId:artifactId:packaging:classifier:version. ■ An archive file or exploded archive directory on the local system. For example, /home/myhome/myapps/helloworld.war. ■ A remote HTTP URL (http://foo/a/b.ear).
stage	boolean	false	When true, indicates that the application needs to be copied into the target server staging area before deployment. By default, nostage is true for the Administration Server and stage is true for the Managed Server targets.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: submod@mod-jms.xml@target or submoduleName@target.
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. When not specified, all configured targets are used. For a new application, the default target is the Administration Server.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of -1 means wait forever. Default value is: -1
upload	boolean	false	When true, copies the source files to the Administration Server's upload directory prior to deployment. Use this setting when running the plug-in remotely (using the remote parameter) and when the user lacks normal access to the Administration Server's file system. Default value is: false
user	java.lang.String	false	Specifies the administrative user name.
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use this goal to prepare deployment files for deployment.

3.3.5 install

Full Name

```
com.oracle.weblogic:weblogic-maven-plugin:install
```

Description

Installs WebLogic Server from a JAR.

Parameters**Table 3–8** *install Parameters*

Name	Type	Required	Description
artifactLocation	java.lang.String	true	<p>Specifies the address of the installation. The address can be one of the following:</p> <ul style="list-style-type: none"> ■ A colon (:) separated list of Maven coordinates of the form: groupId:artifactId:packaging:classifier:version. ■ A file on the local system (/home/myhome/myapps/wls_generic.jar). ■ A remote HTTP URL (http://myarchive/installers/wls_generic.jar).
installCommand	java.lang.String	false	<p>Installs the product with a binary or jar installer (including the quickstart installers.) The following macros are supported:</p> <ul style="list-style-type: none"> ■ @INSTALLER_FILE@ - the path to the installer file. ■ @INSTALL_TO_LOCATION@ - the target directory (only relevant for the quickstart installer). ■ @JAVA_HOME@ - path to the Java home. ■ @JAVA_TMPDIR@ - path to the Java temporary directory. ■ @RESPONSE_FILE@ - path to the OUI silent installer response file. ■ @INV_PTR_LOC_FILE@ - path to the OUI invPtrLoc file. <p>JAR installer example:</p> <pre>@JAVA_HOME@/bin/java -Xms512m -Xmx1024m -Djava.io.tmpdir=@JAVA_TMPDIR@ -jar @INSTALLER_FILE@ -silent -responseFile @RESPONSE_FILE@ -invPtrLoc @INV_PTR_LOC_FILE@</pre> <p>Quick Start JAR installer example:</p> <pre>@JAVA_HOME@/bin/java -Xms512m -Xmx1024m -Djava.io.tmpdir=@JAVA_TMPDIR@ -jar @INSTALLER_FILE@ ORACLE_HOME=@INSTALL_TO_ LOCATION@</pre> <p>This parameter is optional.</p> <p>If specified for a quickstart installer when the supplementalQuickStartLocation parameter is supplied, the same command is used for the supplemental quickstart installer by replacing the @INSTALLER_FILE@ macro with the file location derived from the supplementalQuickStartLocation parameter.</p> <p>If the @INSTALLER_FILE@ macro is not being used, the install goal replaces the argument following the '-jar' argument in the installCommand string with the supplemental quickstart installer JAR file name.</p>
installDir	java.lang.String	true	Deprecated. Use the middlewareHome parameter instead.
invPtrLoc	java.lang.String	false	The silent installer inventory location file. This is required on Unix-based platforms when using the binary or JAR installers.

Table 3–8 (Cont.) install Parameters

Name	Type	Required	Description
middlewareHome	java.lang.String	false	The ORACLE_HOME directory to install into when using the quickstart installer.
quickStartInstaller	boolean	false	Indicates that this is a quickstart installer. The quickstart installer requires you to specify the artifactLocation and installDir parameter. All other parameters are ignored when this parameter is set to true. The default value is false.
response	java.lang.String	false	Deprecated. Use the responseFile parameter instead.
responseFile	java.lang.String	false	The silent installer response file. This is required when using the binary or jar installers.
supplementalQuickStartLocation	java.lang.String	false	The Quick Start supplemental installer.

Usage Example

Use this goal to install WebLogic Server into a local directory so it can be used to execute other goals, as well as to create a WebLogic Server domain for deploying and testing the application represented as the Maven project.

Note: The install goal creates a single managed server called `myserver`, and does not create a domain. Most other goals, including [create-domain](#), use a default server name of `AdminServer`. You therefore need to override the default `AdminServer` server name in your POM.

This goal installs WebLogic Server using a specified installation distribution. You specify the location of the distribution using the `artifactLocation` configuration parameter, which can be the location of the distribution as a file on the file system; an HTTP URL which can be accessed; or a Maven coordinate of the distribution installed in a Maven repository. Specify the `artifactLocation` configuration element in the `weblogic-maven-plugin` section of the `pom.xml` file, or by using the `-DartifactLocation` property when invoking Maven.

[Example 3–7](#) shows an example of installing WebLogic Server using a JAR file on a Windows-based system.

3.3.6 list-apps

Full Name

com.oracle.weblogic:weblogic-maven-plugin:list-apps

Description

Lists the deployment names for applications and standalone modules deployed, distributed, or installed in the domain. Does not require a local server installation.

Parameters

Table 3–9 *list-apps Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
noversion	boolean	false	When true, ignore all version-related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the <code>-list</code> action.
password	java.lang.String	false	Specifies the administrative password.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the <code>source</code> parameter specifies a path on the server, unless the <code>upload</code> parameter is also used.
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of -1 means wait forever. Default value is: -1
user	java.lang.String	false	Specifies the administrative user name.

Table 3–9 (Cont.) list-apps Parameters

Name	Type	Required	Description
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use the list-apps goal to list the deployment names.

```

3.3.7 purge-tasks

Full Name

com.oracle.weblogic:weblogic-maven-plugin:purge-tasks

Description

Flushes out retired deployment tasks.

Parameters

Table 3–10 *purge-tasks Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
debug	boolean	false	When true, compiles debugging information into class files. Default value is: false
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
password	java.lang.String	false	Specifies the administrative password.
user	java.lang.String	false	Specifies the administrative user name.

Table 3–10 (Cont.) purge-tasks Parameters

Name	Type	Required	Description
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information during the deployment process. Default value is: false

Use the `purge-tasks` goal to flush out retired deployment tasks.

```
<execution>
<id>wls-purge</id>
<phase>pre-integration-test</phase>
<goals>
<goal>purge-tasks</goal>

3.3.8 redeploy

Full Name

com.oracle.weblogic:weblogic-maven-plugin:redeploy

Description

Redeploys a running application or part of a running application. Does not require a local server installation.

Parameters**Table 3–11** *redeploy Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
appversion	java.lang.String	false	Version of the application to start.
deleteFiles	java.lang.String	false	Removes the files specified in this parameter while leaving the application activated. This parameter is valid only for unarchived deployments.
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.
libimplver	java.lang.String	false	Implementation version of a Java EE library or optional package. This option can be used only if the library or package does not include an implementation version in its manifest file.
library	boolean	false	Deploy as a shared Java EE library or optional package.
libspecver	java.lang.String	false	Specification version of a Java EE library or optional package. This option can be used only if the library or package does not include a specification version in its manifest file.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to redeploy an application or library. The partition parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
plan	java.lang.String	false	Specifies the path to the deployment plan.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the source parameter specifies a path on the server, unless the upload parameter is also used.

Table 3–11 (Cont.) redeploy Parameters

Name	Type	Required	Description
removePlanOverride	boolean	false	Removes an overridden deployment plan during a redeploy or update deployment action. For applications or libraries deployed to a resource group, you can override the application configuration defined in a resource group template that a resource group references. To remove an application override, specify the <code>removePlanOverride</code> attribute.
resourceGroupTemplate	java.lang.String	false	Specifies the name of the resource group template on which you want to redeploy an application or library.
retiretimeout	java.lang.Integer	false	Specifies the number of seconds before WebLogic Server undeploys the currently running version of this application or module so that clients can start using a new version. When not specified, a graceful retirement policy is assumed. Default value is: -1
rmiGracePeriod	java.lang.Integer	false	Specifies the number of seconds in the grace period for RMI requests during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. The default value of -1 means no grace period. Default value is: -1
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
source	java.lang.String	false	Specifies the address of the artifact to redeploy. The address can be one of the following: <ul style="list-style-type: none"> ■ A colon (:) separated list of Maven coordinates of the form: groupId:artifactId:packaging:classifier:version. ■ An archive file or exploded archive directory on the local system. For example, /home/myhome/myapps/helloworld.war. ■ A remote HTTP URL (<code>http://foo/a/b.ear</code>).
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: <code>submod@mod-jms.xml@target</code> or <code>submoduleName@target</code> .
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. The default target is <code>AdminServer</code> .
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of -1 means wait forever. Default value is: -1
upload	boolean	false	When true, copies the specified source files to the Administration Server's <code>upload</code> directory prior to redeployment. Use this setting when running the plug-in remotely (using the <code>remote</code> parameter) and when the user lacks normal access to the Administration Server's file system. Default value is: <code>false</code>
user	java.lang.String	false	Specifies the administrative user name.
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.

Table 3–11 (Cont.) redeploy Parameters

Name	Type	Required	Description
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information during the deployment process. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use the redeploy goal to redeploy an application or part of that application.

```
<execution>
<id>wls-redeploy</id>
<phase>pre-integration-test</phase>
<goals>
<goal>redeploy</goal>
</goals>
<configuration>
<adminurl>t3://127.0.0.1:7001</adminurl>
<user>weblogic</user>
<password>password</password>
<source>${project.build.directory}/${project.build.finalName}.${project.packaging}
</source>
</configuration>
</execution>
```

[Example 3–11](#) shows typical redeploy goal output.

Example 3–11 redeploy

```
mvn com.oracle.weblogic:weblogic-maven-plugin:redeploy -Dsource=C:\Oracle\Middleware\Oracle_Home\wlserver\server\lib\MySimpleEjb.jar -Duser=weblogic -Dpassword=password -Dname=ExampleEJB

3.3.9 remove-domain

Full Name

com.oracle.weblogic:weblogic-maven-plugin:remove-domain

Description

Removes a domain directory. The domain must not be running for this goal to succeed. This is a convenience goal for the simple use case. If the domain is already removed, stdout prints a status message but the goal does not fail.

Parameters

Table 3–12 *remove-domain Parameters*

Name	Type	Required	Description
domainHome	java.lang.String	true	The path to the domain directory.
workingDir	java.lang.String	false	Specifies the current working directory. Default value is: \${project.build.directory}/weblogic-maven-plugin)

Use the remove-domain goal to remove a domain directory.

```
<execution>
<id>wls-remove-domain</id>
<phase>pre-integration-test</phase>
<goals>
<goal>remove-domain</goal>
</goals>
<configuration>
<domainHome>${project.build.directory}/base_domain</domainHome>
</configuration>
</execution>
```

[Example 3–13](#) shows typical remove-domain goal output.

Example 3–12 *remove-domain*

```

3.3.10 start-app

Full Name

com.oracle.weblogic:weblogic-maven-plugin:start-app

Description

Starts an application deployed on WebLogic Server. Does not require a local server installation.

Parameters

Table 3–13 *start-app Parameters*

Name	Type	Required	Description
adminmode	boolean	false	When true, switches the application to administration mode so that it accepts only administration requests via a configured administration channel. When false, production mode is assumed. Default value is: false
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
appversion	java.lang.String	false	Specifies the version identifier of the application. When not specified, the currently active version of the application is assumed.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
domainHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
noversion	boolean	false	When true, ignores all version-related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the <code>-list</code> action.

Table 3–13 (Cont.) start-app Parameters

Name	Type	Required	Description
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to start an application or library. The partition parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
planversion	java.lang.String	false	Specifies the version of the deployment plan. When not specified, the currently active version of the application's deployment plan is assumed.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the source parameter specifies a path on the server, unless the upload parameter is also used. Default value is: false
retiretimeout	java.lang.Integer	false	Specifies the number of seconds before WebLogic Server undeploys the currently running version of this application or module so that clients can start using a new version. When not specified, a graceful retirement policy is assumed. Default value is: -1
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: submod@mod-jms.xml@target or submoduleName@target.
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. When not specified, all configured targets are used. For a new application, the default target is all targets to which the application is deployed.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of -1 means wait forever. Default value is: -1
user	java.lang.String	false	Specifies the administrative user name.
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information during the deployment process. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use the start-app goal to start an application.

```

3.3.11 start-server

Full Name

com.oracle.weblogic:weblogic-maven-plugin:start-server

Description

Starts WebLogic Server from a script in the current working directory. This is a convenience goal for the simple use case. If the server is already started, stdout prints a status message but the goal does not fail.

Parameters

Table 3–14 *start-server* Parameters

Name	Type	Required	Description
command	java.lang.String[]	false	Specifies the script to start WebLogic Server. If this parameter is not specified, it will default to either <code>startWebLogic.sh</code> or <code>startWebLogic.cmd</code> , based on the platform.
domainHome	java.lang.String	false	Specifies the path to the WebLogic Server domain. Default value is: <code>\${basedir}/Oracle/Domains/mydomain</code>
httpPingUrl	java.lang.String	false	Specifies the URL that, when pinged, will verify that the server is running.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
timeoutSecs	java.lang.Integer	false	Specifies in seconds, the timeout for the script. Valid when the <code>waitForExit</code> parameter is true. A zero (0) or negative value indicates that the script will not timeout. Default value is: -1
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Usage Example

The `start-server` goal executes a `startWebLogic` command on a given domain, starting the WebLogic Server instance.

```
<execution>
<id>wls-wlst-start-server</id>
<phase>pre-integration-test</phase>
<goals>
<goal>start-server</goal>
</goals>
<configuration>
<domainHome>${project.build.directory}/base_domain</domainHome>
</configuration>
</execution>
```

[Example 3–14](#) shows typical `start-server` goal output.

Example 3–14 *start-server*

```

```

3.3.12 stop-app

Full Name

com.oracle.weblogic:weblogic-maven-plugin:stop-app

Description

Stops an application. Does not require a local server installation.

Parameters

Table 3–15 *stop-app Parameters*

Name	Type	Required	Description
adminmode	boolean	false	When true, switches the application to administration mode so that it accepts only administration requests via a configured administration channel. When false, production mode is assumed. Default value is: false
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
appversion	java.lang.String	false	Specifies the version identifier of the application. When not specified, the currently active version of the application is assumed.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
domainHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
graceful	boolean	false	When true, stops the application after existing HTTP clients have completed their work. When not specified, force shutdown is assumed.
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.

Table 3–15 (Cont.) stop-app Parameters

Name	Type	Required	Description
ignoresessions	boolean	false	When true, ignores pending HTTP sessions during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. Default value is: false
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
noversion	boolean	false	When true, ignores all version-related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the <code>-list</code> action.
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to stop an application or library. The <code>partition</code> parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
planversion	java.lang.String	false	Specifies the version of the deployment plan. When not specified, the currently active version of the application's deployment plan is assumed.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the <code>source</code> parameter specifies a path on the server, unless the <code>upload</code> parameter is also used. Default value is: false
rmiGracePeriod	java.lang.Integer	false	Specifies the number of seconds in the grace period for RMI requests during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. The default value of <code>-1</code> means no grace period. Default value is: <code>-1</code>
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: <code>submod@mod-jms.xml@target</code> or <code>submoduleName@target</code> .
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. When not specified, all configured targets are used.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of <code>-1</code> means wait forever. Default value is: <code>-1</code>
user	java.lang.String	false	Specifies the administrative user name.
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.

Table 3–15 (Cont.) stop-app Parameters

Name	Type	Required	Description
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use the stop-app goal to stop an application.

3.3.13 stop-server

Full Name

com.oracle.weblogic:weblogic-maven-plugin:stop-server

Description

Stops WebLogic Server from a script in the current working directory. This is a convenience goal for the simple use case. If the server is already stopped, stdout prints a status message but the goal does not fail.

Parameters

Table 3–16 *stop-server Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
command	java.lang.String[]	false	Specifies the script to stop WebLogic Server. This will default to stopWebLogic.sh or stopWebLogic.cmd, based on the platform.
domainHome	java.lang.String	false	Specifies the path to the WebLogic Server domain. Default value is: \${basedir}/Oracle/Domains/mydomain
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
outputLog	java.lang.String	false	Specifies the log file to which the script output will be redirected. When not specified, it defaults to stdout.
password	java.lang.String	true	Specifies the administrative password.
timeoutSecs	java.lang.Integer	false	Specifies, in seconds, the timeout for the script. This is valid when the waitForExit parameter is true. A zero (0) or negative value indicates that the script will not timeout. Default value is: -1
user	java.lang.String	true	Specifies the administrative user name.
waitForExit	boolean	false	When true, the plug-in should wait for the script to complete. Default value is: true
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
workingDir	java.lang.String	false	Specifies the working directory for the script. If you do not specify this attribute, it defaults to the current working directory. Default value is the domainHome directory.

Usage Example

The `stop-server` goal stops a server instance using the `stopWebLogic` script in the specified domain.

```
<execution>
<id>wls-wlst-stop-server</id>
<phase>post-integration-test</phase>
<goals>
<goal>stop-server</goal>
</goals>
<configuration>
<domainHome>${project.build.directory}/base_domain</domainHome>
<user>weblogic</user>
<password>password</password>
<adminurl>t3://localhost:7001</adminurl>
</configuration>
</execution>
```

[Example 3-16](#) shows typical `stop-server` goal output.

3.3.14 undeploy

Full Name

com.oracle.weblogic:weblogic-maven-plugin:undeploy

Description

Undeploys the application from WebLogic Server. Stops the deployment unit and removes staged files from target servers. Does not require a local server installation.

Parameters

Table 3–17 undeploy Parameters

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
appversion	java.lang.String	false	Specifies the version identifier of the application. When not specified, the currently active version of the application is assumed.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
graceful	boolean	false	When true, stops the application after existing HTTP clients have completed their work. When not specified, forced shutdown is assumed.
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.

Table 3–17 (Cont.) undeploy Parameters

Name	Type	Required	Description
ignoresessions	boolean	false	When true, ignores pending HTTP sessions during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. Default value is: <code>false</code>
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
noversion	boolean	false	When true, ignores all version-related code paths on the Administration Server. Default value is: <code>false</code>
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the <code>-list</code> action.
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to update an application or library. The <code>partition</code> parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
planversion	java.lang.String	false	Specifies the version of the deployment plan. When not specified, the currently active version of the application's deployment plan is assumed.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the <code>source</code> parameter specifies a path on the server, unless the <code>upload</code> parameter is also used. Default value is: <code>false</code>
resourceGroupTemplate	java.lang.String	false	Specifies the name of the resource group template from which you want to undeploy an application or library.
rmiGracePeriod	java.lang.Integer	false	Specifies the number of seconds in the grace period for RMI requests during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. The default value of <code>-1</code> means no grace period. Default value is: <code>-1</code>
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: <code>submod@mod-jms.xml@target</code> or <code>submoduleName@target</code> .
targets	java.lang.String	false	Specifies a comma-separated list of targets for the current operation. When not specified, all configured targets are used.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of <code>-1</code> means wait forever. Default value is: <code>-1</code>
user	java.lang.String	false	Specifies the administrative user name.

Table 3–17 (Cont.) undeploy Parameters

Name	Type	Required	Description
userConfigFile	java.lang.String	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	java.lang.String	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information during the deployment process. Default value is: false
version	boolean	false	When true, prints the version information. Default value is: false
weblogicHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Use the undeploy goal to undeploy an application from WebLogic Server.

```
<execution>
<id>wls-undeploy</id>
<phase>post-integration-test</phase>
<goals>
<goal>undeploy</goal>
</goals>

3.3.15 uninstall

Full Name

com.oracle.weblogic:weblogic-maven-plugin:uninstall

Description

Uninstalls WebLogic Server.

Parameters

Table 3–18 *uninstall Parameters*

Name	Type	Required	Description
invPtrLoc	java.io.File	true	This parameter is deprecated and ignored.
middlewareHome	java.lang.String	true	The Oracle Middleware installation directory. This parameter is required when uninstalling a server installed using the Quickstart installer. Otherwise, it is ignored and the location in the responseFile is used.
response	java.io.File	true	Deprecated. Use the responseFile parameter.
responseFile	java.io.File	true	The silent installer response file. This is required when using the binary or JAR installers.

Use the `uninstall` goal to uninstall WebLogic Server.

```
<execution>
<id>wls-uninstall-server</id>
<phase>post-integration-test</phase>
<goals>
<goal>uninstall</goal>
</goals>
<configuration>
<middlewareHome>c:/dev/wls12210</middlewareHome>
</configuration>
</execution>
```

[Example 3–18](#) shows an example of uninstalling WebLogic Server in a JAR file installation.

Example 3–18 *uninstall in JAR Installation*

```
mvn com.oracle.weblogic:weblogic-maven-plugin:uninstall
-DresponseFile=c:\wls-temp\response.txt
```

3.3.16 update-app

Full Name

com.oracle.weblogic:weblogic-maven-plugin:update-app

Description

Updates an application's deployment plan by redistributing the plan files and reconfiguring the application based on the new plan contexts. Does not require a local server installation.

Parameters

Table 3–19 *update-app Parameters*

Name	Type	Required	Description
adminurl	java.lang.String	false	Specifies the listen address and listen port of the Administration Server. Default value is: t3://localhost:7001
advanced	boolean	false	When true, prints advanced usage options.
appversion	java.lang.String	false	Specifies the version identifier of the application. When not specified, the currently active version of the application is assumed.
debug	boolean	false	When true, displays debug-level messages to the standard output. Default value is: false
domainHome	java.lang.String	false	This parameter is deprecated in this release and ignored.
examples	boolean	false	When true, displays examples of how to use this plug-in.
failOnError	boolean	false	When true, forces the Mojo to fail the build upon encountering an error if it would otherwise just log the error. Default value is: true
id	java.lang.String	false	Specifies an optional, user-supplied, unique deployment task identifier.
middlewareHome	java.lang.String	false	This parameter is deprecated in this release and ignored.

Table 3–19 (Cont.) update-app Parameters

Name	Type	Required	Description
name	java.lang.String	false	Specifies the deployment name to assign to a newly-deployed application or standalone module.
noversion	boolean	false	When true, ignores all version-related code paths on the Administration Server. Default value is: false
nowait	boolean	false	When true, initiates multiple tasks and then monitors them later with the <code>-list</code> action.
partition	java.lang.String	false	Specifies the name of the partition associated with the resource group on which you want to update an application or library. The <code>partition</code> parameter is optional for partition administrators.
password	java.lang.String	false	Specifies the administrative password.
plan	java.lang.String	false	Specifies the location of the deployment plan.
planversion	java.lang.String	false	Specifies the version of the deployment plan. When not specified, the currently active version of the application's deployment plan is assumed.
remote	boolean	false	When true, specifies that the plug-in is not running on the same machine as the Administration Server. In this case, the <code>source</code> parameter specifies a path on the server, unless the <code>upload</code> parameter is also used. Default value is: false
removePlanOverride	boolean	false	Removes an overridden deployment plan during a <code>redeploy</code> or <code>update</code> deployment action. For applications or libraries deployed to a resource group, you can override the application configuration defined in a resource group template that a resource group references. To remove an application override, specify the <code>removePlanOverride</code> attribute.
resourceGroupTemplate	java.lang.String	false	Specifies the name of the resource group template on which you want to update an application or library.
rmiGracePeriod	java.lang.Integer	false	Specifies the number of seconds in the grace period for RMI requests during graceful shutdown. Can be used only when the <code>graceful</code> parameter is true. The default value of <code>-1</code> means no grace period. Default value is: <code>-1</code>
serverClasspath	java.lang.String	false	This parameter is deprecated in this release and ignored.
submoduletargets	java.lang.String	false	Specifies JMS Server targets for resources defined within a JMS application module. Possible values have the form: <code>submod@mod-jms.xml@target</code> or <code>submoduleName@target</code> .
targets	java.lang.String	false	The targets on which to update the application or module. This attribute can be a comma-separated list. If no targets are specified, all targets are updated.
timeout	java.lang.Integer	false	Specifies the maximum number of seconds WebLogic Server will wait for the deployment task to complete. The default value of <code>-1</code> means wait forever. Default value is: <code>-1</code>

Table 3–19 (Cont.) update-app Parameters

Name	Type	Required	Description
upload	boolean	false	When true, copies the source files to the Administration Server's upload directory prior to deployment. Use this setting when running the plug-in remotely (using the <code>remote</code> parameter) and when the user lacks normal access to the Administration Server's file system. Default value is: <code>false</code>
user	<code>java.lang.String</code>	false	Specifies the administrative user name.
userConfigFile	<code>java.lang.String</code>	false	Specifies the location of a user configuration file to use for the administrative user name and password instead of specifying the user name and password directly in plain text.
userKeyFile	<code>java.lang.String</code>	false	Specifies the location of a user key file to use for encrypting and decrypting the user name and password stored in the user configuration file.
verbose	boolean	false	When true, displays additional status information. Default value is: <code>false</code>
version	boolean	false	When true, prints the version information. Default value is: <code>false</code>
weblogicHome	<code>java.lang.String</code>	false	This parameter is deprecated in this release and ignored.

Use the `update-app` goal to update an application's deployment plan.

```
<execution>
<id>wls-update-app</id>
<phase>pre-integration-test</phase>
<goals>
<goal>update-app</goal>
</goals>
<configuration>
<adminurl>t3://127.0.0.1:7001</adminurl>
<user>weblogic</user>
<password>password</password>
<name>${project.build.finalName}</name>
<plan>${basedir}/misc/myplan.xml</plan>
</configuration>
</execution>
```

[Example 3–19](#) shows typical `wlst` goal output.

Example 3–19 update-app

```
$ mvn com.oracle.weblogic:weblogic-maven-plugin:update-app -Duser=weblogic

3.3.17 wlst

Full Name

com.oracle.weblogic:weblogic-maven-plugin:wlst

Description

This goal is a wrapper for the WLST scripting tool. It requires a server install for WLST online commands.

Note: Beginning in version 12.2.1, there is a single unified version of WLST that automatically includes the WLST environment from all products in the ORACLE_HOME.

Parameters

Table 3–20 *wlst* Parameters

Name	Type	Required	Description
args	java.lang.String	false	<p>Deprecated. Use the scriptArgs parameter to specify the arguments as a list of scriptArg elements.</p> <p>Specifies a string value containing command-line arguments to pass to the WLST Python interpreter. The arguments are delimited by spaces. An argument that contains embedded spaces should be quoted either with single quotes or with escaped double quotes. For example, here is a string for args that contains two parameters:</p> <pre>''Thomas Paine' \"Now is the time that tries men's souls.\"''</pre>
debug	boolean	false	<p>When true, displays additional status information.</p> <p>Default value is: false</p>
executeScriptBeforeFile	boolean	false	<p>When true, specifies whether a script, if supplied, executes before or after the file, if supplied. Either a file or a script is required, and both are allowed. See filename and script parameters.</p> <p>Default value is: true</p>
failOnError	boolean	false	<p>When true, the Maven build fails if the wlst goal fails. The default value is true, and consequently any error condition will cause the build to fail. In some cases, setting failOnError to false will allow the wlst goal to ignore the error.</p> <p>Default value is: true</p>
fileName	java.lang.String	false	<p>Specifies the file path of the WLST Python script to execute. Either a fileName or a script parameter must be specified, and both are allowed.</p>
middlewareHome	java.lang.String	true	<p>The path to the Oracle Middleware install directory.</p>
propertiesFile	java.lang.String	false	<p>Specifies the path to a Java properties file. The property names become defined variables in the WLST Python interpreter and are initialized to the values supplied. For example, if the properties file contains the line "foobar: Very important stuff", the variable foobar can be used in a Python statement in the following manner: "print('foobar has the value: ' + foobar)".</p>
script	java.lang.String	false	<p>Specifies an inline WLST Python script, for example, "print('Hello, world!')".</p> <p>Because Python uses indentation to demarcate nested code blocks, scripts that contain multiple lines must be specified in the POM without any indentation within the pom.xml, unless required for code block demarcation.</p>
scriptArgs	java.lang.String	false	<p>Specifies the command-line arguments to pass to the WLST Python interpreter as a list of string values. If the argument contains any embedded whitespace, the caller must include enclosing single quotes or escaped double quotes within the scriptArg element's value. If scriptArgs is specified, the args parameter (deprecated) is ignored.</p>
serverClasspath	java.lang.String	false	<p>This parameter is deprecated and ignored in this release.</p>

Table 3–20 (Cont.) *wlst* Parameters

Name	Type	Required	Description
weblogicHome	java.lang.String	false	This parameter is deprecated and ignored in this release.
wlstVersion	java.lang.String	false	This parameter is deprecated and ignored in this release.
workingDir	java.lang.String	false	The current working directory where the <i>wlst</i> -script and <i>create-domain</i> goal executes. The default value is: <code>\${project.build.directory}/weblogic-maven-plugin</code>

Usage Example

The *wlst* goal enables the WebLogic Scripting Tool (WLST) to be used to execute scripts that configure resources or perform other operations on a WebLogic Server domain. The *wlst* Maven goal uses the WebLogic Server WLST standard environment so you can use it with all your existing WLST scripts.

You can use the *wlst* goal to execute an external WLST script specified with the `fileName` configuration parameter, or you can specify a sequence of WLST commands within the `pom.xml` file using the script configuration element:

```
<execution>
<id>wls-wlst-server</id>
<phase>post-integration-test</phase>
<goals>
<goal>wlst</goal>
</goals>
<configuration>
<middlewareHome>c:/dev/wls12210</middlewareHome>
<fileName>${project.basedir}/misc/configure_resources.py</fileName>
<args>t3://localhost:7001 weblogic password AdminServer</args>
<script>
print('This is a WLST inline script\n')
print('Next, we run a WLST script to create JMS resources on the server\n')
</script>
<executeScriptBeforeFile>true</executeScriptBeforeFile>
</configuration>
</execution>
```

[Example 3–20](#) shows typical *wlst* goal output.

Example 3–20 *wlst*

```
mvn com.oracle.weblogic:weblogic-maven-plugin:wlst
-DfileName=create-datasource.py

```

By default, the `wlst` goal is bound to the `pre-integration-test` phase. To override the default phase binding for a goal, you can explicitly bind plug-in goals to a particular life cycle phase, for example, to the `post-integration-test` phase, as shown below. The `pom.xml` file binds the `wlst` goal to both the `pre-` and `post-integration-test` phases (a dual phase target). As shown, you can run different scripts in different phases, overriding the default settings, and make modifications according to your needs.

Example `pom.xml` file

```
<project>
  ...
  <executions>
    <execution>
      <id>WLS_SETUP_RESOURCES</id>
      <phase>pre-integration-test</phase>
      <goals>
        <goal>wlst</goal>
      </goals>
      <configuration>
        <fileName>src/main/wlst/create-datasource.py</fileName>
      </configuration>
    </execution>

    <execution>
```

```

<id>WLS_TEARDOWN_RESOURCES</id>
<phase>post-integration-test</phase>
<goals>
  <goal>wlst</goal>
</goals>
<configuration>
  <fileName>src/main/wlst/remove-datasource.py</fileName>
</configuration>
</execution>
</executions>
...
</project>

```

3.3.18 wlst-client

Full Name

com.oracle.weblogic:weblogic-maven-plugin:wlst-client

Description

This goal is a WLST wrapper that does not require a local server install for WLST online commands. If a local server install is not present, this goal supports only WLST online commands.

Parameters

Table 3–21 *wlst-client Parameters*

Name	Type	Required	Description
args	java.lang.String	false	<p>Deprecated. Use the scriptArgs parameter to specify the arguments as a list of scriptArg elements.</p> <p>Specifies a string value containing command-line arguments to pass to the WLST Python interpreter. The arguments are delimited by spaces. An argument that contains embedded spaces should be quoted either with single quotes or with escaped double quotes. For example, here is a string for args that contains two parameters:</p> <pre>'Thomas Paine' \"Now is the time that tries men's souls.\"</pre>
debug	boolean	false	<p>When true, displays additional status information.</p> <p>Default value is: false</p>
executeScriptBeforeFile	boolean	false	<p>When true, specifies whether a script, if supplied, executes before or after the file, if supplied. Either a file or a script is required, and both are allowed. See filename and script parameters.</p> <p>Default value is: true</p>
failOnError	boolean	false	<p>When true, the Maven build fails if the wlst goal fails. The default value is true, and consequently any error condition will cause the build to fail. In some cases, setting failOnError to false will allow the wlst goal to ignore the error.</p> <p>Default value is: true</p>

Table 3–21 (Cont.) *wlst-client* Parameters

Name	Type	Required	Description
fileName	java.lang.String	false	Specifies the file path of the WLST Python script to execute. Either a <code>fileName</code> or a <code>script</code> parameter must be specified, and both are allowed.
middlewareHome	java.lang.String	false	The path to the Oracle Middleware install directory. This parameter is required for any WLST offline commands. If a WLST script uses offline commands without specifying a valid <code>middlewareHome</code> , this <code>wlst-client</code> goal fails.
propertiesFile	java.lang.String	false	Specifies the path to a Java properties file. The property names become defined variables in the WLST Python interpreter and are initialized to the values supplied. For example, if the properties file contains the line <code>foobar: Very important stuff</code> , the variable <code>foobar</code> can be used in a Python statement in the following manner: <code>print('foobar has the value: ' + foobar)</code> .
script	java.lang.String	false	Specifies an inline WLST Python script, for example, <code>print('Hello, world!')</code> . Because Python uses indentation to demarcate nested code blocks, scripts that contain multiple lines must be specified in the POM without any indentation within the <code>pom.xml</code> , unless required for code block demarcation.
scriptArgs	java.lang.String	false	Specifies the command-line arguments to pass to the WLST Python interpreter as a list of string values. If the argument contains any embedded whitespace, the caller must include enclosing single quotes or escaped double quotes within the <code>scriptArg</code> element's value. If <code>scriptArgs</code> is specified, the <code>args</code> parameter (deprecated) is ignored.

Running Scripts With Fusion Middleware Dependencies

If you use the `wlst-client` goal to run WLST scripts that contain Fusion Middleware dependencies, you must first include the `com.oracle.fmwshare` dependency to pull in the necessary libraries needed by those scripts.

The `com.oracle.fmwshare` dependency must be listed before any Fusion Middleware dependencies.

For example, to run a WLST script for SOA, add a dependency on `com.oracle.fmwshare` and SOA, similar to the following:

```
<plugin>
  <groupId>com.oracle.weblogic</groupId>
  <artifactId>weblogic-maven-plugin</artifactId>
  <version>12.2.1-0-0</version>
  <executions>
    <execution>
      <id>soa-wlst-client</id>
      <goals>
        <goal>wlst-client</goal>
      </goals>
      <configuration>
        <fileName>${project.basedir}/misc/doSoaStuff.py</fileName>
        <scriptArgs>
          <scriptArg>${adminUserName}</scriptArg>
          <scriptArg>${adminPassword}</scriptArg>
          <scriptArg>${adminUrl}</scriptArg>
        </scriptArgs>
      </configuration>
    </execution>
  </executions>
</plugin>
```

```

    </execution>
  </executions>
  <dependencies>
    <dependency>
      <groupId>com.oracle.fmwshare</groupId>
      <artifactId>fmwshare-wlst-dependencies</artifactId>
      <version>12.2.1-0-0</version>
      <type>pom</type>
    </dependency>
    <dependency>
      <groupId>com.oracle.soa</groupId>
      <artifactId>soa-wlst-dependencies</artifactId>
      <version>12.2.1-0-0</version>
      <type>pom</type>
    </dependency>
  </dependencies>
</plugin>

```

Usage Example

The `wlst-client` goal enables the WebLogic Scripting Tool (WLST) to be used to execute scripts that configure resources or perform other operations on a WebLogic Server domain. The `wlst-client` goal does not require a local server install for WLST online commands.

The `wlst-client` Maven goal uses the WebLogic Server WLST standard environment so you can use it with all your existing WLST scripts.

You can use the `wlst-client` goal to execute an external WLST script specified with the `fileName` configuration parameter, you can specify a sequence of WLST commands within the `pom.xml` file using the `script` configuration element, or you can use both mechanisms.

For example:

```

<execution>
  <id>wls-wlst-server</id>
  <phase>post-integration-test</phase>
  <goals>
    <goal>wlst-client</goal>
  </goals>
  <configuration>
    <fileName>${project.basedir}/misc/configure_resources.py</fileName>
    <args>t3://some-host:7001 weblogic password AdminServer</args>
    <script>
      print('This is a WLST inline script\n')
      print('Next, we run a WLST script to create JMS resources on the server\n')
    </script>
    <executeScriptBeforeFile>true</executeScriptBeforeFile>
  </configuration>
</execution>

```

[Example 3-20](#) shows typical `wlst-client` goal output.

Example 3-21 `wlst-client`

```

mvn com.oracle.weblogic:weblogic-maven-plugin:wlst-client
  -DfileName=create-datasource.py

```

**** DataSource Details ****

Name: cp
Driver Name: Oracle JDBC driver
DataSource: oracle.jdbc.xa.client.OracleXADataSource
Properties: {user=demo}
State: Running

[INFO] -----
[INFO] BUILD SUCCESS
```

As another example, assume that you have the following simple WLST script:

```
try:
    connect('weblogic', 'password', 't3://10.151.69.120:7001')
    listApplications()
    print('TEST PASS')
except:
    print('TEST FAIL')
```

You can supply this WLST script with the `fileName` configuration parameter, as shown in [Example 3-22](#).

Example 3-22 wlst-client Script Example

```
C:\Oracle\Middleware\Oracle_Home\oracle_common\plugins\maven\com\oracle\maven\or
acle-maven-sync\12.2.1>mvn com.oracle.weblogic:weblogic-maven-plugin:wlst-client

[INFO] BUILD SUCCESS
[INFO] -----
[INFO] Total time: 29.197s
[INFO] Finished at: Wed Aug 19 11:33:51 EDT 2015
[INFO] Final Memory: 18M/45M
[INFO] -----
```

By default, the `wlst` goal is bound to the `pre-integration-test` phase. To override the default phase binding for a goal, you can explicitly bind plug-in goals to a particular life cycle phase, for example, to the `post-integration-test` phase, as shown below. The `pom.xml` file binds the `wlst` goal to both the `pre-` and `post-integration-test` phases (a dual phase target). As shown, you can run different scripts in different phases, overriding the default settings, and make modifications according to your needs.

Example `pom.xml` file

```
<project>
  ....
  <executions>
    <execution>
      <id>WLS_SETUP_RESOURCES</id>
      <phase>pre-integration-test</phase>
      <goals>
        <goal>wlst</goal>
      </goals>
      <configuration>
        <fileName>src/main/wlst/create-datasource.py</fileName>
      </configuration>
    </execution>

    <execution>
      <id>WLS_TEARDOWN_RESOURCES</id>
      <phase>post-integration-test</phase>
      <goals>
        <goal>wlst</goal>
      </goals>
```

```
    <configuration>
      <fileName>src/main/wlst/remove-datasource.py</fileName>
    </configuration>
  </execution>
</executions>
....
</project>
```

exit() is Trapped

`exit()` exits WLST from the user session and closes the scripting shell. By default, WLST calls `System.exit(0)` for the current WLST JVM when exiting WLST. Because `wlst-client` runs inside the same JVM as the Maven build process, the entire Maven build process would exit. To provide for this, the Maven implementation traps WLST `exit()` calls and throws an exception.

Calling `exit()` explicitly from a WLST script is discouraged.

For example, assume you were to modify the previous WLST script example to include `exit()`, as follows:

```
try:
  connect('weblogic','password','t3://10.151.69.120:7001')
  listApplications()
  exit()
  print('TEST PASS')
except:
  print('TEST FAIL')
```

When the Maven implementation traps `exit()`, it throws an exception:

Warning: An insecure protocol was used to connect to the server. To ensure on-the-wire security, the SSL port or Admin port should be used instead.

```
jaxwsejb30ws
```

```
Exiting WebLogic Scripting Tool.
```

```

3.3.19 ws-clientgen

Deprecated

This goal is deprecated in this release.

Full Name

`com.oracle.weblogic:weblogic-maven-plugin:ws-clientgen`

Description

Maven goal to generate JAX-WS client Web service artifacts from a WSDL.

The `ws-clientgen` goal provides a Maven wrapper for the "clientgen" Ant task, which is described in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Note: The `ws-clientgen` goal does not work with the JAX-RPC-only JWS annotations described in "WebLogic-Specific Annotations."

Parameters

Table 3–22 briefly describes the `ws-clientgen` parameters. These parameters are more fully described in Table 2-3 "WebLogic-specific Attributes of the clientgen Ant Task" in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Table 3–22 *ws-clientgen Parameters*

Name	Type	Required	Description
binding bindings	java.lang.String	false	Specifies one or more customization files that specify JAX-WS and JAXB custom binding declarations or SOAP handler files. If there is only one binding element, both <code><binding>./filename</binding></code> and <code><bindings><binding>./filename</binding></bindings></code> are allowed. See Table 3–23 for a description of bindings parameters.
catalog	java.lang.String	false	Specifies an external XML catalog file to resolve external entity references. For more information about creating XML catalog files, see "Using XML Catalogs" in <i>Developing JAX-WS Web Services for Oracle WebLogic Server</i>
copyWsdL	boolean	false	Controls where the WSDL should be copied in the <code>ws-clientgen</code> goal's destination dir.
debug	boolean	false	Turns on additional debug output.
debugLevel	boolean	false	Uses Ant debug levels.
destDir	java.io.File	true	Specifies the directory into which the <code>ws-clientgen</code> goal generates the client source code, WSDL, and client deployment descriptor files. You must specify either the <code>destFile</code> or <code>destDir</code> attribute, but not both.
failOnError	boolean	false	Specifies whether the <code>ws-clientgen</code> goal continues executing in the event of an error. The default value is True.
fork	boolean	false	Specifies whether to execute <code>javac</code> using the JDK compiler externally. The default value is false.
genRuntimeCatalog	boolean	false	Specifies whether the <code>ws-clientgen</code> goal should generate the XML catalog artifacts in the client runtime environment. This value defaults to true.
includeAntRuntime	boolean	false	Specifies whether to include the Ant run-time libraries in the classpath.
includeJavaRuntime	boolean	false	Specifies whether to include the default run-time libraries from the executing VM in the classpath.
jmstransportclient	JMSTransportClient	false	Invoking a WebLogic Web service using JMS transport. Table 3–25 describes the parameters of the <code>jmstransportclient</code> parameter.

Table 3–22 (Cont.) ws-clientgen Parameters

Name	Type	Required	Description
packageName	java.lang.String	false	Specifies the package name into which the generated client interfaces and stub files are packaged.
produce	FileSet	false	There is only one FileSet.
produces	List<FileSet>		There is more than one FileSet.
verbose	boolean	false	Turns on verbose output
wSDL	java.lang.String	true	Specifies a full path name or URL of the WSDL that describes a Web service (either WebLogic or non-WebLogic) for which the client component files should be generated.
wSDLLocation	java.lang.String	false	Controls the value of the wSDLLocation attribute generated on the WebService or WebServiceProvider annotation.
xauthfile	java.lang.String	false	Specifies the authorization file.
xmlCatalog	java.lang.String	false	Not used.

Table 3–23 describes the parameters of the bindings parameter.

Table 3–23 Binding Parameters

Name	Type	Required	Description
file	java.lang.String	false	Specifies a customization file that contains JAX-WS and JAXB custom binding declarations or SOAP handler files.

Table 3–24 describes the parameters of the xmlCatalog parameter.

Table 3–24 xmlCatalog Parameters

Name	Type	Required	Description
refid	java.lang.String	false	Specifies the directories (separated by semi-colons) that the ws-jwsc goal should search for JWS files to compile.

Table 3–25 describes the parameters of the jmstransportclient parameter.

Table 3–25 jmstransportclient Parameters

Name	Type	Required	Description
destinationName	java.lang.String	false	JNDI name of the destination queue or topic. Default value is com.oracle.webservices.jms.RequestQueue.
destinationType	java.lang.String	false	Valid values include: QUEUE or TOPIC. Default value is QUEUE.
replyToName	java.lang.String	false	JNDI name of the JMS destination to which the response message is sent.
targetService	java.lang.String	false	Port component name of the Web service.
jndiInitialContextFactory	java.lang.String	false	Name of the initial context factory class used for JNDI lookup. Default value is weblogic.jndi.WLInitialContextFactory.

Table 3–25 (Cont.) jmstransportclient Parameters

Name	Type	Required	Description
jndiConnectionFactoryName	java.lang.String		JNDI name of the connection factory that is used to establish a JMS connection. Default value is com.oracle.webservices.jms.ConnectionFactory.
jndiUrl	java.lang.String		JNDI provider URL. Default value is t3://localhost:7001.
deliveryMode	java.lang.String		Delivery mode indicating whether the request message is persistent. Valid values are PERSISTENT and NON_PERSISTENT. Default value is PERSISTENT.
timeToLive	long	false	Lifetime, in milliseconds, of the request message. Default value is 180000L.
priority	int	false	JMS priority associated with the request and response message. Default value is 0.
jndiContextParameter	java.lang.String	false	JNDI properties, in a format like: someParameterName1=someValue1 , someParameterName2=someValue2.
bindingVersion	java.lang.String	false	Version of the SOAP JMS binding. Default value is 1.0.
runAsPrincipal	java.lang.String	false	Principal used to run the listening MDB.
runAsRole	java.lang.String	false	Role used to run the listening MDB.
messageType	java.lang.String	false	Message type to use with the request message. Valid values are com.oracle.webservices.api.jms.JMSMessageType.BYTES and com.oracle.webservices.api.jms.JMSMessageType.TEXT. Default value is BYTES.
enableHttpWsdlsAccess	boolean	false	Boolean flag that specifies whether to publish the WSDL through HTTP. Default value is true.
mdbPerDestination	boolean	false	Boolean flag that specifies whether to create one listening message-driven bean (MDB) for each requested destination. Default value is true.
activationConfig	java.lang.String	false	Activation configuration properties passed to the JMS provider.
contextPath	java.lang.String	false	The deployed context of the web service.
serviceUri	java.lang.String	false	Web service URI portion of the URL.
portName	java.lang.String	false	The name of the port in the generated WSDL.

Usage Example

The `ws-clientgen` goal generates client Web service artifacts from a WSDL.

This goal benefits from the convention-over-configuration approach, allowing you to execute it using the defaults of the project.

There are two ways to run the `ws-clientgen` goal:

- From the command line. For example, after you define an alias:

```
mvn -DvariableName1=value1 -DvariableName2=value2
```

```
com.oracle.weblogic:weblogic-maven-plugin:ws-clientgen
```

- By specifying the Maven `generate-resources` life cycle phase. Then run `mvn generate-resources` in the same directory of `pom.xml`.

To do this, modify the `pom.xml` file to specify the `generate-resources` life cycle phase, the `ws-clientgen` goal, and include any parameters you need to set.

Consider the following example:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>maven_plugin.simple</groupId>
  <artifactId>maven_plugin_simple</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>clientgen</id>
            <phase>generate-resources</phase>
            <goals>
              <goal>ws-clientgen</goal>
            </goals>
            <configuration>
              <wsdl>${basedir}/AddNumbers.wsdl</wsdl>
              <dest>${project.build.outputDirectory}</destDir>
              <packageName>maven_plugin.simple.client</packageName>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>
```

[Example 3-23](#) shows typical `ws-clientgen` goal output.

Example 3-23 *ws-clientgen*

3.3.20 wsgen

Full Name

com.oracle.weblogic:weblogic-maven-plugin:wsgen

Description

Maven goal that reads a JAX-WS service endpoint implementation class and generates all of the portable artifacts for a JAX-WS Web service. Use the `wsgen` goal when you are starting from Java classes.

You can then package the service endpoint interface and implementation class, value types, and generated classes, if any, into a WAR file, and deploy the WAR to a Web container.

The `wsgen` goal provides a wrapper for the JAX-WS Maven `wsgen` plug-in goal.

Parameters

[Table 3–26](#) describes the `wsgen` parameters.

Table 3–26 *wsgen* Parameters

Name	Type	Required	Description
<code>args</code>	<code>java.lang.String</code>	false	Specifies optional command-line options. Multiple elements can be specified, and each token must be placed in its own list.
<code>destDir</code>	<code>java.io.File</code>	false	Specifies the full pathname of where to place output generated classes. Use <code>xnocompile</code> to turn this off. The default is <code>\${project.build.outputDirectory}</code> .
<code>encoding</code>	<code>java.lang.String</code>	false	Specifies the character encoding of the output files, such as the deployment descriptors and XML files. Examples of character encodings are SHIFT-JIS and UTF-8. The default value is platform dependent.
<code>extension</code>	boolean	false	<code>extension</code> is always set to <code>true</code> and you do not need to set it. Extensions are not limited to Oracle JAX-WS vendor extensions.
<code>executable</code>	<code>java.lang.String</code>	false	Name of the executable. Can be <code>wsgen</code> .
<code>genWsdL</code>	boolean	false	Specifies that a WSDL file should be generated in <code>\${resourceDestDir}</code> . By default, the WSDL is not generated.
<code>inlineSchemas</code>	boolean	false	Generates inline schemas in a generated WSDL. The default is <code>false</code> . The <code>genWsdL</code> parameter must be set to <code>true</code> .

Table 3–26 (Cont.) wsgen Parameters

Name	Type	Required	Description
jmstransportservice	boolean	false	Use JMS transport for Web services. It can be omitted. See Table 3–34 for a description of <code>jmstransportservice</code> parameters.
keep	boolean	false	Specifies whether to keep generated files. The default is <code>true</code> .
metadata	<code>java.io.File</code>	false	Metadata file for the <code>wsgen</code> task, as described in <i>External Web Service Metadata</i> in <i>JAX-WS Release Documentation</i> . Unmatched files are ignored.
portName	<code>java.lang.String</code>	false	Specify the port name to use in the generated WSDL. The <code>genWsdL</code> parameter must be set to <code>true</code> .
protocol	<code>java.lang.String</code>	false	Use in conjunction with <code>genWsdL</code> to specify the protocol to use in the <code>wsdl:binding</code> . The <code>genWsdL</code> parameter must be set to <code>true</code> . Valid values are <code>soap1.1</code> and <code>Xsoap1.2</code> . The default is <code>soap1.1</code> . <code>Xsoap1.2</code> is non-standard and you can use it only in conjunction with the extension option.
resourceDestDir	<code>java.io.File</code>	false	Specifies the directory to contain the generated WSDL files. The default is <code>\${project.build.directory}/generated-sources/wsdl</code> . The <code>genWsdL</code> parameter must be set to <code>true</code> .
sei	<code>java.lang.String</code>	false	Specifies the service endpoint implementation class name.
servicename	<code>java.lang.String</code>	false	Specify the service name (<code>wsdl:servicename</code>) to use in the generated WSDL. The <code>genWsdL</code> parameter must be set to <code>true</code> .
sourceDestDir	<code>java.io.File</code>	false	Specify where to place generated source files. This parameter also sets <code>keep</code> to <code>true</code> . The default is <code>\${project.build.directory}/generated-sources/wsgen</code> .
verbose	boolean	false	Output messages about what the tool is doing. Default value is: <code>false</code> .
vmArgs	<code>java.util.List</code>	false	Specify optional JVM options. You can specify multiple elements, and each token must be placed in its own list.
xdonotoverwrite	boolean	false	No description provided
xnocompile	boolean	false	Turns off compilation after code generation, and lets the generated sources be compiled by Maven during the compilation phase. The default is <code>false</code> . This parameter also sets <code>keep</code> to <code>true</code> .

Usage Example

The `wsgen` goal reads a JAX-WS service endpoint implementation class and generates all of the portable artifacts for a JAX-WS Web service.

Specify the Maven `process-classes` life cycle phase. Then, run `mvn process-classes` in the same directory of the POM file.

To do this, modify the `pom.xml` file to specify the `process-classes` life cycle phase, the `wsgen` goal, and include any parameters you need to set. Consider the following example:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>maven_plugin.simple</groupId>
```

```

<artifactId>maven_plugin_simple</artifactId>
<version>1.0</version>
<build>
<sourceDirectory>./</sourceDirectory>
  <plugins>
    <plugin>
      <groupId>com.oracle.weblogic</groupId>
      <artifactId>weblogic-maven-plugin</artifactId>
      <version>12.2.1-0-0</version>
      <executions>
        <execution>
          <id>wsgen</id>
          <phase>process-classes</phase>
          <goals>
            <goal>wsgen</goal>
          </goals>
          <configuration>
            <destDir>${project.build.directory}/wsgenOutput/</destDir>
            <sei>myexample.IPInfo</sei>
            <verbose>true</verbose>
            <genWsdL>true</genWsdL>
          </configuration>
        </execution>
      </executions>
    </plugin>
  </plugins>
</build>
</project>

```

Example 3–24 shows typical wsgen goal output.

Example 3–24 wsgen

```

        GetIpAddressResponse.class
```

3.3.21 wsimport

Full Name

com.oracle.weblogic:weblogic-maven-plugin:wsimport

Description

Maven goal that parses a WSDL and binding files and generates the Java code needed to access it. Use the wsimport goal when you are starting from a WSDL.

The wsimport goal provides a wrapper for the JAX-WS Maven wsimport goal.

Parameters

[Table 3-27](#) describes the wsimport parameters.

Table 3–27 *wsimport Parameters*

Name	Type	Required	Description
args	java.lang.String	false	Specifies optional command-line options. Multiple elements can be specified, and each token must be placed in its own list.
bindingDirectory	java.io.File	false	Directory containing binding files.
bindingFiles	java.util.List	false	List of files to use for bindings. If not specified, all .xml files in the bindingDirectory are used.
catalog	java.io.File	false	Catalog file to resolve external entity references support TR9401, XCatalog, and OASIS XML Catalog format.
destDir	java.io.File	false	Specifies the full pathname of where to place output generated classes. Use xnocompile to turn this off. The default is <code>\${project.build.outputDirectory}</code> .
encoding	java.lang.String	false	Specifies the character encoding of the output files, such as the deployment descriptors and XML files. Examples of character encodings are SHIFT-JIS and UTF-8. The default is platform dependent.
executable	java.lang.String	false	Name of the executable. Can be <code>wsimport</code> .
extension	boolean	false	<code>extension</code> is always set to <code>true</code> and you do not need to set it. Extensions are not limited to Oracle JAX-WS vendor extensions.
genJWS	boolean	false	Generate stubbed JWS implementation file. The default is <code>false</code> .
httpproxy	java.lang.String	false	Set HTTP/HTTPS proxy. Format is <code>[user[:password]@]proxyHost[:proxyPort]</code> .
implDestDir	java.io.File	false	Specify where to generate JWS implementation file.
implPortName	java.lang.String	false	Local portion of port name for generated JWS implementation. Implies <code>genJWS=true</code> . Note: It is a QName string, formatted as: <code>"{" + Namespace URI + "}" + local part</code> .
implServiceName	java.lang.String	false	Local portion of service name for generated JWS implementation. Implies <code>genJWS=true</code> . Note: It is a QName string, formatted as: <code>"{" + Namespace URI + "}" + local part</code> .
jmstransportclient	JMSTransportClient	false	Invoking a WebLogic Web service using JMS transport. Table 3–25 describes the parameters of the <code>jmstransportclient</code> parameter.
jmsUri	jmsUri	false	Override <code>jmsUri</code> defined in a WSDL file. Requires <code>extension=true</code> .
keep	boolean	false	Specifies whether to keep generated files. The default is <code>true</code> .
packageName	java.lang.String	false	The package in which the source files will be generated.
quiet	boolean	false	Suppress <code>wsimport</code> output. The default is <code>false</code> .
sourceDestDir	java.io.File	false	Specify where to place generated source files. This parameter also sets <code>keep</code> to <code>true</code> . The default is <code>\${project.build.directory}/generated-sources/wsimport</code> .
staleFile	java.io.File	false	The folder containing flag files used to determine if the output is stale. If you do not specify a folder, the default is <code>\${project.build.directory}/jaxws/stale</code> .

Table 3–27 (Cont.) wsimport Parameters

Name	Type	Required	Description
target	java.lang.String	false	Generate code as per the given JAXWS specification version. Setting "2.0" will cause JAX-WS to generate artifacts that run with JAX-WS 2.0 runtime.
verbose	boolean	false	Output messages about what the tool is doing. Default value is: false.
vmArgs	java.lang.String	false	Specify optional JVM options. You can specify multiple elements, and each token must be placed in its own list.
wSDLDirectory	java.io.File	false	Directory containing WSDL files.
wSDLFiles	java.util.List	false	List of files to use for WSDLs. If not specified, all .wSDL files in the wSDLDirectory will be used.
wSDLLocation	java.lang.String	false	<p>@WebService.wSDLLocation and @WebServiceClient.wSDLLocation value.</p> <p>Can end with asterisk, in which case relative path of the WSDL will be appended to the given wSDLLocation.</p> <p>Example:</p> <pre> ... <configuration> <wSDLDirectory>src/mywSDls</wSDLDirectory> <wSDLFiles> <wSDLFile>a.wSDL</wSDLFile> <wSDLFile>b/b.wSDL</wSDLFile> <wSDLFile>\${basedir}/src/mywSDls/c.wSDL</wSDLFile> </wSDLFiles> <wSDLLocation>http://example.com/mywebservice/*</wSDLLocation> </configuration> ... wSDLLocation for a.wSDL will be http://example.com/mywebservice/a.wSDL wSDLLocation for b/b.wSDL will be http://example.com/mywebservice/b/b.wSDL wSDLLocation for \${basedir}/src/mywSDls/c.wSDL will be file://absolute/path/to/c.wSDL </pre> <p>Note: External binding files cannot be used if asterisk notation is in place.</p>
wSDLUrls	java.util.List	false	List of external WSDL URLs to be compiled.
xadditionalHeaders	boolean	false	Maps headers not bound to the request or response messages to Java method parameters.
xauthFile	java.io.File	false	Specify the location of authorization file.
xdebug	boolean	false	Turn on debug message. The default is false.
xdisableAuthenticator	boolean	false	Disable Authenticator used by JAX-WS RI, xauthfile will be ignored if set.
xdisableSSLHostnameVerification	boolean	false	Disable the SSL Hostname verification while fetching WSDL(s).

Table 3–27 (Cont.) wsimport Parameters

Name	Type	Required	Description
xjcArgs	java.util.List	false	Specify optional XJC-specific parameters that should simply be passed to xjc using -B option of WsImport command. Multiple elements can be specified, and each token must be placed in its own list.
xnoAddressingDataBinding	boolean	false	Binding W3C EndpointReferenceType to Java. By default WsImport follows spec and does not bind EndpointReferenceType to Java and uses the spec provided W3CEndpointReference.
xnocompile	boolean	false	Turns off compilation after code generation, and lets the generated sources be compiled by Maven during the compilation phase. The default is true. This parameter also sets keep to true.
xuseBaseResourceAndURLToLoadWSDL	boolean	false	No description provided by JAX-WS Maven wsimport.

Usage Example

The `wsimport` goal parses a WSDL and binding files and generates Java code needed to access the Web service.

You can use the `wsimport` goal in two ways:

- To generate the client-side artifacts. Then, implement the client to invoke the Web service.
- To create your own implementation of the Web service. Use `wsimport` goal with the `genJWS` parameter to generate portable artifacts and a stubbed implementation file. You then implement the service endpoint.

Specify the Maven `generate-sources` life cycle phase. Then, run `mvn generate-sources` in the same directory of the POM file.

Assume that you want to import the WSDL shown in [Example 3–25](#).

Example 3–25 WSDL to Import

```
<?xml version='1.0' encoding='UTF-8'?><!-- Published by JAX-WS RI at

            <soap:body use="literal" />
        </output>
    </operation>
</binding>
<service name="SampleWs">
    <port name="SampleWsPort" binding="tns:SampleWsPortBinding">
        <soap:address
location="jms:jndi:com.oracle.webservices.api.jms.RequestQueue?targetService=Sampl
eWs&amp;jndiURL=t3://localhost:7001&amp;messageType=BYTES&amp;deliveryMode=PERSIST
ENT" />
    </port>
</service>
</definitions>

```

To import this WSDL, modify the `pom.xml` file to specify the `generate-sources` life cycle phase, the `wsimport` goal, the WSDL location, and include any parameters you need to set. This example uses a local WSDL file for demonstration purposes.

Consider the following example:

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
```

```

<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>maven_plugin.simple</groupId>
  <artifactId>maven_plugin_simple</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>wsimport-jmssample</id>
            <goals>
              <goal>wsimport</goal>
            </goals>
            <phase>generate-sources</phase>
            <configuration>
              <wsdlFiles>
                <wsdlFile>${basedir}/import-example/SampleWs.wsdl</wsdlFile>
              </wsdlFiles>
              <genJWS>true</genJWS>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>

```

[Example 3–26](#) shows typical `wsimport` goal output.

Example 3–26 *wsimport*

```

mvn -Dfile=pom.xml generate-sources

```

3.3.22 ws-wsdlc

Deprecated

This goal is deprecated in this release.

Full Name

`com.oracle.weblogic:weblogic-maven-plugin:ws-wsdlc`

Description

Maven goal to generate a set of artifacts and a partial Java implementation of the Web service from a WSDL.

The `ws-wsdlc` goal provides a Maven wrapper for the "wsdlc" Ant task, which is described in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Parameters

[Table 3-28](#) briefly describes the `ws-wsdlc` parameters. These parameters are more fully described in Table 2-3 "WebLogic-specific Attributes of the clientgen Ant Task" in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Table 3–28 *ws-wsdlc Parameters*

Name	Type	Required	Description
bindings	java.lang.String	false	Customization files that specify JAX-WS and JAXB custom binding declarations or SOAP handler files.
catalog	java.lang.String	false	Specifies an external XML catalog file. For more information about creating XML catalog files, see "Using XML Catalogs" in <i>Developing JAX-WS Web Services for Oracle WebLogic Server</i>
debug	boolean	false	Specifies the flag to set when debugging the process. Default value is false.
debugLevel	java.lang.String	false	Uses Ant debug levels.
destImplDir	java.lang.String	false	Specifies the directory into which the stubbed-out JWS implementation file is generated.
destJavadocDir	java.lang.String	false	Specifies the directory into which the Javadoc that describes the JWS interface is generated.
destJwsDir	java.lang.String	true	Specifies the directory into which the JAR file that contains the JWS interface and data binding artifacts should be generated.
explode	boolean	false	Specifies the flag to set if you want exploded output. Defaults to true.
failOnError	boolean	false	Specifies whether the ws-clientgen goal continues executing in the event of an error. The default value is true
fork	boolean	false	Specifies whether to execute javac using the JDK compiler externally. The default value is false.
includeAntRuntime	boolean	false	Specifies whether to include the Ant run-time libraries in the classpath. The default value is true.
includeJavaRuntime	boolean	false	Specifies whether to include the default run-time libraries from the executing VM in the classpath. The default value is false.
optimize	boolean	false	Specifies the flag to set if you want optimization. Defaults to true.
packageName	java.lang.String	false	Specifies the package into which the generated JWS interface and implementation files should be generated.
srcPortName	java.lang.String	false	Specifies the name of the WSDL port from which the JWS interface file should be generated. Set the value of this parameter to the value of the name parameter of the port parameter that corresponds to the Web service port for which you want to generate a JWS interface file. The port parameter is a child of the service parameter in the WSDL file. If you do not specify this attribute, ws-wsdlc generates a JWS interface file from the service specified by srcServiceName.
srcServiceName	java.lang.String	false	Specifies the name of the Web service from which the JWS interface file should be generated.
srcWsdL	java.lang.String	true	Specifies the name of the WSDL from which to generate the JAR file that contains the JWS interface and data binding artifacts.
verbose	boolean	false	Specifies the flag to set if you want verbose output. Default value is false.

Usage Example

The `ws-wsdlc` goal generates a set of artifacts and a partial Java implementation of the Web service from a WSDL.

This goal benefits from the convention-over-configuration approach, allowing you to execute it using the defaults of the project.

There are two ways to run the `ws-wsdlc` goal:

- From the command line. For example, after you define an alias:

```
mvn -DvariableName1=value1 -DvariableName2=value2
com.oracle.weblogic:weblogic-maven-plugin:ws-wsdlc
```

- By specifying the Maven `generate-resources` life cycle phase.

To do this, modify the `pom.xml` file to specify the `generate-resources` life cycle phase, the `ws-wsdlc` goal, and include any parameters you need to set. Then run `mvn generate-resources` in the same directory of `pom.xml`.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>maven_plugin.simple</groupId>
  <artifactId>maven_plugin_simple</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>wsdlc</id>
            <phase>generate-resources</phase>
            <goals>
              <goal>ws-wsdlc</goal>
            </goals>
            <configuration>
              <srcWsdL>${basedir}/AddNumbers.wsdl</srcWsdL>
              <destJwsDir>${project.build.directory}/jwsImpl</destJwsDir>
              <destImplDir>${project.build.directory}/output</destImplDir>
              <packageName>maven_plugin.simple</packageName>
              <verbose>>true</verbose>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>
```

[Example 3-27](#) shows typical `ws-wsdlc` goal output.

Example 3-27 ws-wsdlc

```
mvn -f wsdlc_pom.xml generate-resources

3.3.23 ws-jwsc

Deprecated

This goal is deprecated in this release.

Full Name

com.oracle.weblogic:weblogic-maven-plugin:ws-jwsc

Description

Maven goal to build a JAX-WS web service.

The `ws-jwsc` goal provides a Maven wrapper for the "jwsc" Ant task, which is described in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Note: The `ws-jwsc` goal does not work with the JAX-RPC-only JWS annotations described in "WebLogic-Specific Annotations."

Nested Configuration in module Elements

The `ws-jwsc` goal supports nested configuration elements, as shown in bold in [Example 3-28](#). See Introduction to the POM for information on Maven projects with multiple modules.

Example 3-28 Nested Configuration Elements

```

<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>com.test.ws</groupId>
  <artifactId>test-ws-jwsc1</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>first-jwsc</id>
            <phase>generate-resources</phase>

```

```

    <goals>
      <goal>ws-jwsc</goal>
    </goals>
    <configuration>
      <srcDir>${basedir}/src/main/java</srcDir>
      <destDir>${project.build.directory}/jwscOutput
        /${project.build.finalName}</destDir>
      <listfiles>true</listfiles>
      <debug>true</debug>

      <module>
        <name>pocreate</name>
        <contextPath>mypub</contextPath>
        <compiledWsdL>D:\maven-test\order_wsdL.jar</compiledWsdL >

        <jws>
          <file>examples/wsee/jwsc/POCreateImpl.java</file>
          <transportType>
            <type>WLHttpTransport</type>
            <serviceUri>POCreate</serviceUri>
            <portName>POCreatePort</portName>
          </transportType>
        </jws>
        <jws>
          ...
        </jws>
        <descriptors>
          <descriptor>"resources/web.xml"</descriptor/>
          <descriptor>"resources/weblogic.xml"</descriptor />
        </descriptors>
      </module>
      <module>
        ...
      </module>
    </modules>
  </configuration>
</execution>
</executions>
</plugin>
</plugins>
</build>
</project>

```

These nested configuration elements for `ws-jwsc` have the following conditions:

- You must use at least one of the following elements: `jws`, `jwses`, `module`, or `modules`.
- Collection elements such as `jwses` and `modules` elements can be omitted.
- If there is only one child element within the collection element, the collection element can also be removed.

For example, if there is only one `jws` element, use `jws`. If there are multiple `jws` elements, add all of the `jws` elements under a `jwses` element.

- As with the JWSC ant task, if `module` has only one `jws` child element, then other sub elements of `module` can be nested into `jwsc` and `jwsc/transportType`.

[Example 3–29](#) shows an example without a `module` element in which the `jws` parameter is a child of `ws-jwsc`.

Example 3–29 jws Element as Child of ws-jwsc Goal

```

<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>com.test.ws</groupId>
  <artifactId>test-ws-jwsc</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>first-jwsc</id>
            <phase>compile</phase>
            <goals>
              <goal>ws-jwsc</goal>
            </goals>
            <configuration>
              <srcDir>${basedir}/src/main/java</srcDir>
              <destDir>${project.build.directory}/jwscOutput/
                ${project.build.finalName}</destDir>
              <jws>
                <!-- no parent <module> -->
                <file>examples/wsee/jwsc/POCreateImpl.java</file>
                <compiledWsd1>${project.build.directory}/purchaseorder_wsd1.jar>
                <transportType>
                  <type>WLHttpTransport</type>
                </transportType>
              </jws>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>

```

ws-jwsc Parameters

[Table 3–29](#) briefly describes the `ws-jwsc` parameters. These parameters are more fully described in [Table 2-3 "WebLogic-specific Attributes of the clientgen Ant Task"](#) in *WebLogic Web Services Reference for Oracle WebLogic Server*.

Table 3–29 *ws-jwsc Parameters*

Name	Type	Required	Description
applicationXml	java.lang.String	false	Specifies the full name and path of the application.xml deployment descriptor of the Enterprise Application. If you specify an existing file, the ws-jwsc goal updates it to include the Web services information. However, jwsc does not automatically copy the updated application.xml file to the destDir; you must manually copy this file to the destDIR. If the file does not exist, jwsc creates it. The ws-jwsc goal also creates or updates the corresponding weblogic-application.xml file in the same directory. If you do not specify this attribute, jwsc creates or updates the file destDir/META-INF/application.xml, where destDir is the jwsc attribute.
debug	boolean	false	Turns on additional debug output.
destDir	java.lang.String	true	Specifies the full pathname of the directory that will contain the compiled JWS files, XML Schemas, WSDL, and generated deployment descriptor files, all packaged into a JAR or WAR file.
destEncoding	java.lang.String	false	Specifies the character encoding of the output files, such as the deployment descriptors and XML files. Examples of character encodings are SHIFT-JIS and UTF-8. The default value of this attribute is UTF-8.
jws	Jws	false	There is only one <jws> element. See Table 3–30 for a description of jws parameters.
jwses	Jws	false	It contains more than one <jws> element.
keepGenerated	boolean	false	Specifies whether the Java source files and artifacts generated by this goal should be regenerated if they already exist. If you specify false, new Java source files and artifacts are always generated and any existing artifacts are overwritten. If you specify true, the goal regenerates only those artifacts that have changed, based on the timestamp of any existing artifacts
listfiles	boolean	false	Specifies whether to list all of the files.
module	Module	false	It contains one <module> element. See Table 3–31 for a description of module parameters.
modules	Module	false	It contains more than one <module> element.
optimize	boolean	false	Specifies the flag to set when optimization is required. Defaults to true.
sourcepath	java.lang.String	true	The full pathname of top-level directory that contains the Java files referenced by the JWS file, such as JavaBeans used as parameters or user-defined exceptions.
srcDir	java.lang.String	true	Specifies the full pathname of the top-level directory that contains the JWS file you want to compile.
srcEncoding	java.lang.String	false	Specifies the character encoding of the input files, such as the JWS file or configuration XML files. Examples of character encodings are SHIFT-JIS and UTF-8. The default value of this attribute is the character encoding set for the JVM.
verbose	boolean	false	Specifies verbose output

jws Parameter

As described in "jws", the `jws` parameter specifies the name of a JWS file that implements your Web service and for which the `ws-jwsc` goal should generate Java code and supporting artifacts, and then package them into a deployable WAR file inside of an Enterprise Application.

You can specify the `jws` parameter in two ways:

- An immediate child element of the `ws-jwsc` goal. In this case, `ws-jwsc` generates a separate WAR file for each JWS file. You typically use this method if you are specifying just one JWS file to the `ws-jwsc` goal.
- A child element of the `module` parameter, which in turn is a child of the `ws-jwsc` goal. In this case, `ws-jwsc` generates a single WAR file that includes all the generated code and artifacts for all the JWS files grouped within the `module` parameter.

This method is useful if you want all JWS files to share supporting files, such as common Java data types.

[Table 3–30](#) describes the child parameters of the `jws` parameter. The description specifies whether the parameter applies in the case that `jws` is a child of the `ws-jwsc` goal, is a child of `module`, or both.

Table 3–30 *jws Parameters*

Name	Type	Required	Description	Child of <code>ws-jwsc</code> , <code>module</code> , or both
<code>compiledWsdL</code>	<code>java.lang.String</code>	false	Specifies the full pathname of the JAR file generated by the <code>ws-wsdLc</code> goal based on an existing WSDL file. Only required for the "starting from WSDL" use case.	both
<code>contextPath</code>	<code>java.lang.String</code>	false	Specifies the deployed context of the web service.	<code>ws-jwsc</code>
<code>explode</code>	boolean	false	Specifies the flag to set when you want exploded output. Defaults to true.	<code>ws-jwsc</code>
<code>file</code>	<code>java.lang.String</code>	true	The name of the JWS file that you want to compile. The <code>ws-jwsc</code> goal looks for the file in the <code>srcdir</code> directory.	both
<code>generateWsdL</code>	boolean	true	Specifies whether the generated WAR file includes the WSDL file in the <code>WEB-INF</code> directory. Default value is false.	both
<code>jmstransportService</code>	boolean	false	Use JMS transport for Web services. It can be omitted. See Table 3–34 for a description of <code>jmstransportService</code> parameters.	<code>ws-jwsc</code>
<code>name</code>	<code>java.lang.String</code>	false	Specifies the name of the generated WAR file (or exploded directory, if the <code>explode</code> attribute is set to true) that contains the deployable Web service.	<code>ws-jwsc</code>

Table 3–30 (Cont.) jws Parameters

Name	Type	Required	Description	Child of ws-jwsc, module, or both
transportType	transportType	false	Used when it contains only one transport type element. It can be omitted. See Table 3–33 for a description of transportType parameters.	both
transportTypes	transportType	false	Used when it contains more than one transport type element. It can be omitted. See Table 3–33 for a description of transportType parameters.	both
wsdlOnly	boolean	false	Specifies that only a WSDL file should be generated for this JWS file. The default value is false.	ws-jwsc

module Parameters

As described in "module", the `module` parameter groups one or more `jws` parameters together so that their generated code and artifacts are packaged in a single Web application (WAR) file. The `module` parameter is a child of the `ws-jwsc` goal.

[Table 3–31](#) describes the parameters of the `module` parameter.

Table 3–31 module Parameters

Name	Type	Required	Description
clientgen	java.lang.String	false	There is only one <clientgen> element. It can be omitted.
clientgens	java.lang.String	false	There is more than one <clientgen> element. It can be omitted.
contextPath	java.lang.String	false	Specifies the deployed context of the Web service.
descriptor	java.lang.String	false	Specifies the web.xml descriptor to use if a new one should not be generated. The path should be fully qualified. The files should be separated by ", ".
ejbWsInWar	boolean	false	Specifies whether to package EJB-based Web services in a WAR file instead of a JAR file.
explode	boolean	false	Specifies the flag to set when you want exploded output. Defaults to true.
FileSet	FileSet	false	Used when it contains one FileSet element. It can be omitted.
FileSets	FileSet	false	Used when it contains more than one FileSet element. It can be omitted.
generateWsdL	boolean	true	Specifies whether the generated WAR file includes the WSDL file in the WEB-INF directory. Default value is false.
jws	Jws	false	Used when it contains one jws element. It can be omitted.
jwses	Jws	false	Used when it contains more than one jws element. It can be omitted.

Table 3–31 (Cont.) module Parameters

Name	Type	Required	Description
name	java.lang.String	false	Specifies the name of the WAR to use when evaluating the ear file.
wsdlOnly	boolean	false	Specifies that only a WSDL file should be generated for this JWS file. The default value is false.
zipfileset	java.lang.String	false	There is only one <zipfileset> element.

FileSet Parameters

As described in "fileset", the `FileSet` parameter specifies one or more directories in which the `ws-jwsc` goal searches for JWS files to compile. The list of JWS files that `ws-jwsc` finds is then treated as if each file had been individually specified with the `jws` parameter of `module`.

The `FileSet` parameter is a child of the `ws-jwsc` goal.

[Table 3–32](#) describes the parameters of the `FileSet` parameter.

Table 3–32 FileSet Parameters

Name	Type	Required	Description
srcDir	java.lang.String	true	Specifies the directories (separated by semi-colons) that the <code>ws-jwsc</code> goal should search for JWS files to compile.
prefix	java.lang.String	false	Prefix to use.
sourceIncludes	java.lang.String	false	Specifies the explicit includes-list for the file set.
sourceExcludes	java.lang.String	false	Specifies the explicit excludes-list for the file set.

TransportType Parameters

As described in "WLHttpTransport", "WLHttpsTransport", and "WLJMSTransport", you use transport parameters to specify the transport type, context path, and service URI sections of the URL used to invoke the Web service, as well as the name of the port in the generated WSDL.

The `ws-jwsc` goal combines these transport parameters into one, `TransportType`.

[Table 3–32](#) describes the parameters of the `transportType` parameter.

Table 3–33 transportType Parameters

Name	Type	Required	Description
transportTypeName	java.lang.String	true	Specifies the value is <code>WLHttpTransport</code> , <code>WLHttpsTransport</code> , or <code>WLJMSTransport</code> . Default value is <code>WLHttpTransport</code> .
serviceUri	java.lang.String	false	Specifies the Web service URI portion of the URL.
contextPath	java.lang.String	false	Specifies the deployed context of the Web service.
portName	java.lang.String	false	Specifies the name of the port in the generated WSDL.

Table 3–34 describes the parameters of the `jmstransport-service` parameter.

Table 3–34 *jmstransport-service Parameters*

Name	Type	Required	Description
<code>destinationName</code>	<code>java.lang.String</code>	false	JNDI name of the destination queue or topic. Default value is <code>com.oracle.webservices.jms.RequestQueue</code> .
<code>destinationType</code>	<code>java.lang.String</code>	false	Valid values include: <code>QUEUE</code> or <code>TOPIC</code> . Default value is <code>QUEUE</code> .
<code>replyToName</code>	<code>java.lang.String</code>	false	JNDI name of the JMS destination to which the response message is sent.
<code>targetService</code>	<code>java.lang.String</code>	false	Port component name of the Web service.
<code>jndiInitialContextFactory</code>	<code>java.lang.String</code>	false	Name of the initial context factory class used for JNDI lookup. Default value is <code>weblogic.jndi.WLInitialContextFactory</code> .
<code>jndiConnectionFactoryName</code>	<code>java.lang.String</code>		JNDI name of the connection factory that is used to establish a JMS connection. Default value is <code>com.oracle.webservices.jms.ConnectionFactory</code> .
<code>jndiUrl</code>	<code>java.lang.String</code>		JNDI provider URL. Default value is <code>t3://localhost:7001</code> .
<code>deliveryMode</code>	<code>java.lang.String</code>		Delivery mode indicating whether the request message is persistent. Valid values are <code>PERSISTENT</code> and <code>NON_PERSISTENT</code> . Default value is <code>PERSISTENT</code> .
<code>timeToLive</code>	<code>long</code>	false	Lifetime, in milliseconds, of the request message. Default value is <code>180000L</code> .
<code>priority</code>	<code>int</code>	false	JMS priority associated with the request and response message. Default value is <code>0</code> .
<code>jndiContextParameter</code>	<code>java.lang.String</code>	false	JNDI properties, in a format like: <code>someParameterName1=someValue1 ,</code> <code>someParameterName2=someValue2</code> .
<code>bindingVersion</code>	<code>java.lang.String</code>	false	Version of the SOAP JMS binding. Default value is <code>1.0</code> .
<code>runAsPrincipal</code>	<code>java.lang.String</code>	false	Principal used to run the listening MDB.
<code>runAsRole</code>	<code>java.lang.String</code>	false	Role used to run the listening MDB.
<code>messageType</code>	<code>java.lang.String</code>	false	Message type to use with the request message. Valid values are <code>com.oracle.webservices.api.jms.JMSMessageType.BYTES</code> and <code>com.oracle.webservices.api.jms.JMSMessageType.TEXT</code> . Default value is <code>BYTES</code> .
<code>enableHttpWsdlsAccess</code>	<code>boolean</code>	false	Boolean flag that specifies whether to publish the WSDL through HTTP. Default value is <code>true</code> .
<code>mdbPerDestination</code>	<code>boolean</code>	false	Boolean flag that specifies whether to create one listening message-driven bean (MDB) for each requested destination. Default value is <code>true</code> .
<code>activationConfig</code>	<code>java.lang.String</code>	false	Activation configuration properties passed to the JMS provider.

Table 3–34 (Cont.) jmstransportservice Parameters

Name	Type	Required	Description
contextPath	java.lang.String	false	The deployed context of the web service.
serviceUri	java.lang.String	false	Web service URI portion of the URL.
portName	java.lang.String	false	The name of the port in the generated WSDL.

Usage Example

The `ws-jwsc` goal builds a JAX-WS web service.

This goal benefits from the convention-over-configuration approach, allowing you to execute it using the defaults of the project.

To run the `ws-jwsc` goal, specify the Maven `generate-resources` phase.

To do this, modify the `pom.xml` file to specify the `generate-resources` phase, the `ws-jwsc` goal, and include any parameters you need to set. Then run `mvn generate-resources` in the same directory of `pom.xml`.

```
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
<project>
  <modelVersion>4.0.0</modelVersion>
  <groupId>maven_plugin.simple</groupId>
  <artifactId>maven_plugin_simple</artifactId>
  <version>1.0</version>
  <build>
    <plugins>
      <plugin>
        <groupId>com.oracle.weblogic</groupId>
        <artifactId>weblogic-maven-plugin</artifactId>
        <version>12.2.1-0-0</version>
        <executions>
          <execution>
            <id>jwsc</id>
            <phase>generate-resources</phase>
            <goals>
              <goal>ws-jwsc</goal>
            </goals>
            <configuration>
              <destDir>${project.build.directory}/jwscOutput/
              <listfiles>true</listfiles>
              <debug>true</debug>
              <jws>
                <!-- no parent <module> -->
                <file>examples/wsee/jwsc/POCreateImpl.java</file>
                <compiledWsd1>${project.build.directory}/purchaseorder_wsd1.jar<
                <transportType>
                  <type>WLHttpTransport</type>
                </transportType>
              </jws>
              <verbose>true</verbose>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>
```

[Example 3-30](#) shows typical `ws-jwsc` goal output.

Creating a Split Development Directory Environment

This chapter describes how to create a WebLogic Server split development directory that you can use to develop a Java EE application or module.

This chapter includes the following sections:

- [Section 4.1, "Overview of the Split Development Directory Environment"](#)
- [Section 4.2, "Using the Split Development Directory Structure: Main Steps"](#)
- [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#)
- [Section 4.4, "Organizing Shared Classes in a Split Development Directory"](#)
- [Section 4.5, "Generating a Basic build.xml File Using weblogic.BuildXMLGen"](#)
- [Section 4.6, "Developing Multiple-EAR Projects Using the Split Development Directory"](#)
- [Section 4.7, "Best Practices for Developing WebLogic Server Applications"](#)

4.1 Overview of the Split Development Directory Environment

The WebLogic split development directory environment consists of a directory layout and associated Ant tasks that help you repeatedly build, change, and deploy Java EE applications. Compared to other development frameworks, the WebLogic split development directory provides these benefits:

- **Fast development and deployment.** By minimizing unnecessary file copying, the split development directory Ant tasks help you recompile and redeploy applications quickly *without* first generating a deployable archive file or exploded archive directory.
- **Simplified build scripts.** The Oracle-provided Ant tasks automatically determine which Java EE modules and classes you are creating, and build components in the correct order to support common classpath dependencies. In many cases, your project build script can simply identify the source and build directories and allow Ant tasks to perform their default behaviors.
- **Easy integration with source control systems.** The split development directory provides a clean separation between source files and generated files. This helps you maintain only editable files in your source control system. You can also clean the build by deleting the entire build directory; build files are easily replaced by rebuilding the project.

4.1.1 Source and Build Directories

The source and build directories form the basis of the split development directory environment. The source directory contains all editable files for your project—Java source files, editable descriptor files, JSPs, static content, and so forth. You create the source directory for an application by following the directory structure guidelines described in [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#).

The top level of the source directory always represents an enterprise application (.ear file), even if you are developing only a single Java EE module. Subdirectories beneath the top level source directory contain:

- Enterprise Application Modules (EJBs and Web applications)

Note: The split development directory structure does not provide support for developing new Resource Adapter components.

- Descriptor files for the enterprise application (application.xml and weblogic-application.xml)
- Utility classes shared by modules of the application (for example, exceptions, constants)
- Libraries (compiled .jar files, including third-party libraries) used by modules of the application

The build directory contents are generated automatically when you run the `wlcompile` ant task against a valid source directory. The `wlcompile` task recognizes EJB, Web application, and shared library and class directories in the source directory, and builds those components in an order that supports common class path requirements. Additional Ant tasks can be used to build Web services or generate deployment descriptor files from annotated EJB code.

Figure 4–1 Source and Build Directories

The build directory contains only those files generated during the build process. The combination of files in the source and build directories form a deployable Java EE application.

The build and source directory contents can be placed in any directory of your choice. However, for ease of use, the directories are commonly placed in directories named `source` and `build`, within a single project directory (for example, `\myproject\build` and `\myproject\source`).

4.1.2 Deploying from a Split Development Directory

All WebLogic Server deployment tools (`weblogic.Deployer`, `wldeploy`, and the WebLogic Server Administration Console) support direct deployment from a split development directory. You specify only the build directory when deploying the application to WebLogic Server.

WebLogic Server attempts to use all classes and resources available in the `source` directory for deploying the application. If a required resource is not available in the source directory, WebLogic Server then looks in the application's build directory for that resource. For example, if a deployment descriptor is generated during the build process, rather than stored with source code as an editable file, WebLogic Server obtains the generated file from the build directory.

WebLogic Server discovers the location of the source directory by examining the `.beabuild.txt` file that resides in the top level of the application's build directory. If you ever move or modify the source directory location, edit the `.beabuild.txt` file to identify the new source directory name.

[Section 6.1, "Deploying Applications Using `wldeploy`"](#) describes the `wldeploy` Ant task that you can use to automate deployment from the split directory environment.

[Figure 4–2](#) shows a typical deployment process. The process is initiated by specifying the build directory with a WebLogic Server tool. In the figure, all compiled classes and generated deployment descriptors are discovered in the build directory, but other application resources (such as static files and editable deployment descriptors) are missing. WebLogic Server uses the hidden `.beabuild.txt` file to locate the application's source directory, where it finds the required resources.

Figure 4–2 Split Directory Deployment

4.1.3 Split Development Directory Ant Tasks

Oracle provides a collection of Ant tasks designed to help you develop applications using the split development directory environment. Each Ant task uses the source, build, or both directories to perform common development tasks:

- `wlcompile`—This Ant task compiles the contents of the source directory into subdirectories of the build directory. `wlcompile` compiles Java classes and also processes annotated `.ejb` files into deployment descriptors, as described in [Section 5.1, "Compiling Applications Using `wlcompile`"](#).
- `wlappc`—This Ant task invokes the `appc` compiler, which generates JSPs and container-specific EJB classes for deployment. See [Section 5.2, "Building Modules and Applications Using `wlappc`"](#).
- `wldeploy`—This Ant task deploys any format of Java EE applications (exploded or archived) to WebLogic Server. To deploy directly from the split development directory environment, you specify the build directory of your application. See [Section B, "wldeploy Ant Task Reference"](#).
- `wlpackage`—This Ant task uses the contents of both the source and build directories to generate an EAR file or exploded EAR directory that you can give to others for deployment.

4.2 Using the Split Development Directory Structure: Main Steps

The following steps illustrate how you use the split development directory structure to build and deploy a WebLogic Server application.

1. Create the main EAR source directory for your project. When using the split development directory environment, you must develop Web applications and EJBs as part of an enterprise application, even if you do not intend to develop multiple Java EE modules. See [Section 4.3, "Organizing Java EE Components in a Split](#)

Development Directory".

2. Add one or more subdirectories to the EAR directory for storing the source for Web applications, EJB components, or shared utility classes. See [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#) and [Section 4.4, "Organizing Shared Classes in a Split Development Directory"](#).
3. Store all of your editable files (source code, static content, editable deployment descriptors) for modules in subdirectories of the EAR directory. Add the entire contents of the source directory to your source control system, if applicable.
4. Set your WebLogic Server environment by executing either the `setWLSEnv.cmd` (Windows) or `setWLSEnv.sh` (UNIX) script. The scripts are located in the `WL_HOME\server\bin\` directory, where `WL_HOME` is the top-level directory in which WebLogic Server is installed.

Note: On UNIX operating systems, the `setWLSEnv.sh` command does not set the environment variables in all command shells. Oracle recommends that you execute this command using the Korn shell or bash shell.

5. Use the `weblogic.BuildXMLGen` utility to generate a default `build.xml` file for use with your project. Edit the default property values as needed for your environment. See [Section 4.5, "Generating a Basic build.xml File Using weblogic.BuildXMLGen"](#).
6. Use the default targets in the `build.xml` file to build, deploy, and package your application. See [Section 4.5, "Generating a Basic build.xml File Using weblogic.BuildXMLGen"](#) for a list of default targets.

4.3 Organizing Java EE Components in a Split Development Directory

The split development directory structure requires each project to be staged as a Java EE enterprise application. Oracle therefore recommends that you stage even standalone Web applications and EJBs as modules of an enterprise application, to benefit from the split directory Ant tasks. This practice also allows you to easily add or remove modules at a later date, because the application is already organized as an EAR.

Note: If your project requires multiple EARs, see also [Section 4.6, "Developing Multiple-EAR Projects Using the Split Development Directory"](#).

The following sections describe the basic conventions for staging the following module types in the split development directory structure:

- [Section 4.3.2, "Enterprise Application Configuration"](#)
- [Section 4.3.3, "Web Applications"](#)
- [Section 4.3.4, "EJBs"](#)
- [Section 4.4.1, "Shared Utility Classes"](#)
- [Section 4.4.2, "Third-Party Libraries"](#)

The directory examples are taken from the `splitdir` sample application installed in `ORACLE_HOME\wlserver\samples\server\examples\src\examples\splitdir`, where

`ORACLE_HOME` represents the directory in which you installed WebLogic Server. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

4.3.1 Source Directory Overview

The following figure summarizes the source directory contents of an enterprise application having a Web application, EJB, shared utility classes, and third-party libraries. The sections that follow provide more details about how individual parts of the enterprise source directory are organized.

Figure 4-3 Overview of Enterprise Application Source Directory

4.3.2 Enterprise Application Configuration

The top level source directory for a split development directory project represents an enterprise application. The following figure shows the minimal files and directories required in this directory.

Figure 4–4 Enterprise Application Source Directory

The enterprise application directory will also have one or more subdirectories to hold a Web application, EJB, utility class, and/or third-party Jar file, as described in the following sections.

4.3.3 Web Applications

Web applications use the basic source directory layout shown in the figure below.

Figure 4-5 Web Application Source and Build Directories

The key directories and files for the Web application are:

- `helloWebApp\` —The top level of the Web application module can contain JSP files and static content such as HTML files and graphics used in the application. You can also store static files in any named subdirectory of the Web application (for example, `helloWebApp\graphics` or `helloWebApp\static`.)
- `helloWebApp\WEB-INF\` —Store the Web application's editable deployment descriptor files (`web.xml` and `weblogic.xml`) in the `WEB-INF` subdirectory.
- `helloWebApp\WEB-INF\src` —Store Java source files for Servlets in package subdirectories under `WEB-INF\src`.

When you build a Web application, the `appc` Ant task and `jspc` compiler compile JSPs into package subdirectories under `helloWebApp\WEB-INF\classes\jsp_servlet` in the build directory. Editable deployment descriptors are not copied during the build process.

4.3.4 EJBs

EJBs use the source directory layout shown in the figure below.

Figure 4-6 EJB Source and Build Directories

The key directories and files for an EJB are:

- `helloEJB\` —Store all EJB source files under package directories of the EJB module directory. The source files can be either `.java` source files, or annotated `.ejb` files.
- `helloEJB\META-INF\` —Store editable EJB deployment descriptors (`ejb-jar.xml` and `weblogic-ejb-jar.xml`) in the `META-INF` subdirectory of the EJB module directory. The `helloWorldEar` sample does not include a `helloEJB\META-INF` subdirectory, because its deployment descriptors files are generated from annotations in the `.ejb` source files. See [Section 4.3.5, "Important Notes Regarding EJB Descriptors"](#).

During the build process, EJB classes are compiled into package subdirectories of the `helloEJB` module in the build directory. If you use annotated `.ejb` source files, the build process also generates the EJB deployment descriptors and stores them in the `helloEJB\META-INF` subdirectory of the build directory.

4.3.5 Important Notes Regarding EJB Descriptors

EJB deployment descriptors should be included in the source `META-INF` directory and treated as source code *only* if those descriptor files are created from scratch or are edited manually. Descriptor files that are generated from annotated `.ejb` files should appear only in the build directory, and they can be deleted and regenerated by building the application.

For a given EJB component, the EJB source directory should contain either:

- EJB source code in `.java` source files and editable deployment descriptors in `META-INF`

or:

- EJB source code with descriptor annotations in `.ejb` source files, and *no editable descriptors* in `META-INF`.

In other words, do not provide both annotated `.ejb` source files and editable descriptor files for the same EJB component.

4.4 Organizing Shared Classes in a Split Development Directory

The WebLogic split development directory also helps you store shared utility classes and libraries that are required by modules in your enterprise application. The following sections describe the directory layout and classloading behavior for shared utility classes and third-party JAR files.

4.4.1 Shared Utility Classes

Enterprise applications frequently use Java utility classes that are shared among application modules. Java utility classes differ from third-party JARs in that the source files are part of the application and must be compiled. Java utility classes are typically libraries used by application modules such as EJBs or Web applications.

Figure 4-7 Java Utility Class Directory

Place the source for Java utility classes in a named subdirectory of the top-level enterprise application directory. Beneath the named subdirectory, use standard package subdirectory conventions.

During the build process, the `wlcompile` Ant task invokes the `javac` compiler and compiles Java classes into the `APP-INF/classes/` directory under the build directory. This ensures that the classes are available to other modules in the deployed application.

4.4.2 Third-Party Libraries

You can extend an enterprise application to use third-party `.jar` files by placing the files in the `APP-INF/lib\` directory, as shown below:

Figure 4–8 Third-party Library Directory

Third-party JARs are generally not compiled, but may be versioned using the source control system for your application code. For example, XML parsers, logging implementations, and Web application framework JAR files are commonly used in applications and maintained along with editable source code.

During the build process, third-party JAR files are not copied to the build directory, but remain in the source directory for deployment.

4.4.3 Class Loading for Shared Classes

The classes and libraries stored under `APP-INF/classes` and `APP-INF/lib` are available to all modules in the enterprise application. The application classloader always attempts to resolve class requests by first looking in `APP-INF/classes`, then `APP-INF/lib`.

4.5 Generating a Basic build.xml File Using weblogic.BuildXMLGen

After you set up your source directory structure, use the `weblogic.BuildXMLGen` utility to create a basic `build.xml` file. `weblogic.BuildXMLGen` is a convenient utility that generates an Ant `build.xml` file for enterprise applications that are organized in the split development directory structure. The utility analyzes the source directory and creates build and deploy targets for the enterprise application as well as individual modules. It also creates targets to clean the build and generate new deployment descriptors.

Additionally, optional packages are supported as Java EE shared libraries in `weblogic.BuildXMLGen`, whereby all manifests of an application and its modules are scanned to look for optional package references. If optional package references are found they are added to the compile and `appc` tasks in the generated `build.xml` file.

For example, if a library located at `lib\echolib.jar` is referenced as an optional package, the tasks generated by `weblogic.BuildXMLGen` will contain an `appc` task that would appear as follows:

```

<target name="appc" description="Runs weblogic.appc on your application">
  <wlappc source="${dest.dir}" verbose="${verbose}">
    <library file="lib\echolib\echolib.jar" />
  </wlappc>
</target>

```

The compile and appc tasks for modules also use the lib\echolib\echolib.jar library.

4.5.1 weblogic.BuildXMLGen Syntax

The syntax for weblogic.BuildXMLGen is as follows:

```
java weblogic.BuildXMLGen [options] <source directory>
```

where options include:

- -help—Print standard usage message
- -version—Print version information
- -projectName <project name>—Name of the Ant project
- -d <directory>—Directory where build.xml is created. The default is the current directory.
- -file <build.xml>—Name of the generated build file
- -librarydir <directories>—Create build targets for shared Java EE libraries in the comma-separated list of directories. See [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."](#)
- -username <username>—User name for deploy commands
- -password <password>—User password

After running weblogic.BuildXMLGen, edit the generated build.xml file to specify properties for your development environment. The list of properties you need to edit are shown in the listing below.

Example 4-1 build.xml Editable Properties

```
<!-- BUILD PROPERTIES ADJUST THESE FOR YOUR ENVIRONMENT -->
<property name="tmp.dir" value="/tmp" />
<property name="dist.dir" value="${tmp.dir}/dist"/>
<property name="app.name" value="helloWorldEar" />
<property name="ear" value="${dist.dir}/${app.name}.ear"/>
<property name="ear.exploded" value="${dist.dir}/${app.name}_exploded"/>
<property name="verbose" value="true" />
<property name="user" value="USERNAME" />
<property name="password" value="PASSWORD" />
<property name="servername" value="myserver" />
<property name="adminurl" value="iiop://localhost:7001" />
```

In particular, make sure you edit the tmp.dir property to point to the build directory you want to use. By default, the build.xml file builds projects into a subdirectory tmp.dir named after the application (/tmp/helloWorldEar in the above listing).

The following listing shows the default main targets created in the build.xml file. You can view these targets at the command prompt by entering the ant -projecthelp command in the EAR source directory.

Example 4-2 Default build.xml Targets

appc	Runs weblogic.appc on your application
build	Compiles helloWorldEar application and runs appc
clean	Deletes the build and distribution directories
compile	Only compiles helloWorldEar application, no appc
compile.appStartup	Compiles just the appStartup module of the application

compile.appUtils	Compiles just the appUtils module of the application
compile.build.orig	Compiles just the build.orig module of the application
compile.helloEJB	Compiles just the helloEJB module of the application
compile.helloWebApp	Compiles just the helloWebApp module of the application
compile.javadoc	Compiles just the javadoc module of the application
deploy	Deploys (and redeploys) the entire helloWorldEar application
descriptors	Generates application and module descriptors
ear	Package a standard J2EE EAR for distribution
ear.exploded	Package a standard exploded J2EE EAR
redploy.appStartup	Redeploys just the appStartup module of the application
redploy.appUtils	Redeploys just the appUtils module of the application
redploy.build.orig	Redeploys just the build.orig module of the application
redploy.helloEJB	Redeploys just the helloEJB module of the application
redploy.helloWebApp	Redeploys just the helloWebApp module of application
redploy.javadoc	Redeploys just the javadoc module of the application
undeploy	Undeploys the entire helloWorldEar application

4.6 Developing Multiple-EAR Projects Using the Split Development Directory

The split development directory examples and procedures described previously have dealt with projects consisting of a single enterprise application. Projects that require building multiple enterprise applications simultaneously require slightly different conventions and procedures, as described in the following sections.

Note: The following sections refer to the MedRec sample application, which consists of three separate enterprise applications as well as shared utility classes, third-party JAR files, and dedicated client applications. The MedRec source and build directories are installed under `ORACLE_HOME/user_projects/domain/medrec`, where `ORACLE_HOME` is the directory you specified as Oracle Home when you installed Oracle WebLogic Server. For more information, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

4.6.1 Organizing Libraries and Classes Shared by Multiple EARs

For single EAR projects, the split development directory conventions suggest keeping third-party JAR files in the `APP-INF/lib` directory of the EAR source directory. However, a multiple-EAR project would require you to maintain a copy of the same third-party JAR files in the `APP-INF/lib` directory of *each* EAR source directory. This introduces multiple copies of the source JAR files, increases the possibility of some JAR files being at different versions, and requires additional space in your source control system.

To address these problems, consider editing your build script to copy third-party JAR files into the `APP-INF/lib` directory of the *build* directory for each EAR that requires the libraries. This allows you to maintain a single copy and version of the JAR files in your source control system, yet it enables each EAR in your project to use the JAR files.

The MedRec sample application installed with WebLogic Server uses this strategy, as shown in the following figure.

Figure 4–9 Shared JAR Files in MedRec

MedRec takes a similar approach to utility classes that are shared by multiple EARs in the project. Instead of including the source for utility classes within the scope of each ear that needs them, MedRec keeps the utility class source independent of all EARs. After compiling the utility classes, the build script archives them and copies the JARs into the build directory under the APP-INF/LIB subdirectory of each EAR that uses the classes, as shown in figure [Figure 4–9](#).

4.6.2 Linking Multiple build.xml Files

When developing multiple EARs using the split development directory, each EAR project generally uses its own `build.xml` file (perhaps generated by multiple runs of `weblogic.BuildXMLGen`). Applications like MedRec also use a master `build.xml` file that calls the subordinate `build.xml` files for each EAR in the application suite.

Ant provides a core task (named `ant`) that allows you to execute other project build files within a master `build.xml` file. The following line from the MedRec master build file shows its usage:

```
<ant inheritAll="false" dir="${root}/startupEar" antfile="build.xml"/>
```

The above task instructs Ant to execute the file named `build.xml` in the `/startupEar` subdirectory. The `inheritAll` parameter instructs Ant to pass only user properties from the master build file to the `build.xml` file in `/startupEar`.

MedRec uses multiple tasks similar to the above to build the `startupEar`, `medrecEar`, and `physicianEar` applications, as well as building common utility classes and client applications.

4.7 Best Practices for Developing WebLogic Server Applications

Oracle recommends the following "best practices" for application development.

- Package applications as part of an enterprise application. See [Section 6.2, "Packaging Applications Using `wlpackage`"](#).

- Use the split development directory structure. See [Section 4.3, "Organizing Java EE Components in a Split Development Directory"](#).
- For distribution purposes, package and deploy in archived format. See [Section 6.2, "Packaging Applications Using wlpkgmgr"](#).
- In most other cases, it is more convenient to deploy in exploded format. See [Section 6.2.1, "Archive versus Exploded Archive Directory"](#).
- Never deploy untested code on a WebLogic Server instance that is serving production applications. Instead, set up a development WebLogic Server instance on the same computer on which you edit and compile, or designate a WebLogic Server development location elsewhere on the network.
- Even if you do not run a development WebLogic Server instance on your development computer, you must have access to a WebLogic Server distribution to compile your programs. To compile any code using WebLogic or Java EE APIs, the Java compiler needs access to the `weblogic.jar` file and other JAR files in the distribution directory. Install WebLogic Server on your development computer to make WebLogic distribution files available locally.

Building Applications in a Split Development Directory

This chapter describes how to build WebLogic Server Java EE applications using the WebLogic split development directory environment.

This chapter includes the following sections:

- [Section 5.1, "Compiling Applications Using wlcompile"](#)
- [Section 5.2, "Building Modules and Applications Using wlappc"](#)

5.1 Compiling Applications Using wlcompile

You use the `wlcompile` Ant task to invoke the `javac` compiler to compile your application's Java components in a split development directory structure. The basic syntax of `wlcompile` identifies the source and build directories, as in this command from the `helloWorldEar` sample:

```
<wlcompile srcdir="${src.dir}" destdir="${dest.dir}"/>
```

Note: Deployment descriptors are no longer mandatory as of Java EE 5; therefore, exploded module directories must indicate the module type by using the `.war` or `.jar` suffix when there is no deployment descriptor in these directories. The suffix is required so that `wlcompile` can recognize the modules. The `.war` suffix indicates the module is a Web application module and the `.jar` suffix indicates the module is an EJB module.

The following is the order in which events occur using this task:

1. `wlcompile` compiles the Java components into an output directory:

```
ORACLE_  
HOME\wlserver\samples\server\examples\build\helloWorldEar\APP-INF\classes\
```

where `ORACLE_HOME` represents the directory in which you installed WebLogic Server. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

2. `wlcompile` builds the EJBs and automatically includes the previously built Java modules in the compiler's classpath. This allows the EJBs to call the Java modules without requiring you to manually edit their classpath.

3. Finally, `wlcompile` compiles the Java components in the Web application with the EJB and Java modules in the compiler's classpath. This allows the Web applications to refer to the EJB and application Java classes without requiring you to manually edit the classpath.

5.1.1 Using includes and excludes Properties

More complex enterprise applications may have compilation dependencies that are not automatically handled by the `wlcompile` task. However, you can use the `include` and `exclude` options to `wlcompile` to enforce your own dependencies. The `includes` and `excludes` properties accept the names of enterprise application modules—the names of subdirectories in the enterprise application source directory—to include or exclude them from the compile stage.

The following line from the `helloWorldEar` sample shows the `appStartup` module being excluded from compilation:

```
<wlcompile srcdir="${src.dir}" destdir="${dest.dir}"
  excludes="appStartup"/>
```

5.1.2 wlcompile Ant Task Attributes

Table 5–1 contains Ant task attributes specific to `wlcompile`.

Table 5–1 *wlcompile Ant Task Attributes*

Attribute	Description
<code>srcdir</code>	The source directory.
<code>destdir</code>	The build/output directory.
<code>classpath</code>	Allows you to change the classpath used by <code>wlcompile</code> .
<code>includes</code>	Allows you to include specific directories from the build.
<code>excludes</code>	Allows you to exclude specific directories from the build.
<code>librarydir</code>	Specifies a directory of shared Java EE libraries to add to the classpath. See Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."

5.1.3 Nested javac Options

The `wlcompile` Ant task can accept nested `javac` options to change the compile-time behavior. For example, the following `wlcompile` command ignores deprecation warnings and enables debugging:

```
<wlcompile srcdir="${mysrcdir}" destdir="${mybuilddir}">
  <javac deprecation="false" debug="true"
    debuglevel="lines,vars,source"/>
</wlcompile>
```

5.1.4 Setting the Classpath for Compiling Code

Most WebLogic services are based on Java EE standards and are accessed through standard Java EE packages. The WebLogic and other Java classes required to compile programs that use WebLogic services are packaged in the `wls-api.jar` file in the `lib` directory of your WebLogic Server installation. In addition to `wls-api.jar`, include the following in your compiler's `CLASSPATH`:

- The `lib\tools.jar` file in the JDK directory, or other standard Java classes required by the Java Development Kit you use.
- The `examples.property` file for Apache Ant (for examples environment). This file is discussed in the WebLogic Server documentation on building examples using Ant located at: `samples\server\examples\src\examples\examples.html`
- Classes for third-party Java tools or services your programs import.
- Other application classes referenced by the programs you are compiling.

5.1.5 Library Element for `wlcompile` and `wlapcc`

The `library` element is an optional element used to define the name and optional version information for a module that represents a shared Java EE library required for building an application, as described in [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."](#) The `library` element can be used with both `wlcompile` and `wlapcc`, described in [Section 5.2, "Building Modules and Applications Using wlapcc"](#).

The name and version information are specified as attributes to the `library` element, described in [Table 5-2](#).

Table 5-2 Library attributes

Attribute	Description
<code>file</code>	Required filename of a Java EE library
<code>name</code>	The optional name of a required Java EE library.
<code>specificationversion</code>	An optional specification version required for the library.
<code>implementationversion</code>	An optional implementation version required for the library.

The format choices for both `specificationversion` and `implementationversion` are described in [Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application"](#). The following output shows a sample `library` reference:

```
<library file="c:\mylibs\lib.jar" name="ReqLib" specificationversion="920"
implementationversion="1.1" />
```

5.2 Building Modules and Applications Using wlapcc

To reduce deployment time, use the `weblogic.appc` Java class (or its equivalent Ant task `wlapcc`) to pre-compile a deployable archive file, (WAR, JAR, or EAR). Precompiling with `weblogic.appc` generates certain helper classes and performs validation checks to ensure your application is compliant with the current Java EE specifications. The application-level checks include checks between the application-level deployment descriptors and the individual modules, as well as validation checks across the modules.

Additionally, optional packages are supported as Java EE shared libraries in `appc`, whereby all manifests of an application and its modules are scanned to look for optional package references.

`wlapcc` is the Ant task interface to the `weblogic.appc` compiler. The following section describe the `wlapcc` options and usage. Both `weblogic.appc` and the `wlapcc` Ant task compile modules in the order in which they appear in the `application.xml` deployment descriptor file that describes your enterprise application.

5.2.1 wlapcc Ant Task Attributes

[Table 5–3](#) describes Ant task options specific to `wlapcc`. These options are similar to the `weblogic.appc` command-line options, but with a few differences.

Notes: See [Section 5.2.4, "weblogic.appc Reference"](#) for a list of `weblogic.appc` options.

See also [Section 5.1.5, "Library Element for wlapcc and wlapcc"](#).

Table 5–3 *wlapcc* Ant Task Attributes

Option	Description
<code>print</code>	Prints the standard usage message.
<code>version</code>	Prints <code>appc</code> version information.
<code>output <file></code>	Specifies an alternate output archive or directory. If not set, the output is placed in the source archive or directory.
<code>forceGeneration</code>	Forces generation of EJB and JSP classes. Without this flag, the classes may not be regenerated (if determined to be unnecessary).
<code>lineNumbers</code>	Adds line numbers to generated class files to aid in debugging.
<code>writeInferredDescriptors</code>	Specifies that the application or module contains deployment descriptors with annotation information.
<code>basicClientJar</code>	Does not include deployment descriptors in client JARs generated for EJBs.
<code>idl</code>	Generates IDL for EJB remote interfaces.
<code>idlOverwrite</code>	Always overwrites existing IDL files.
<code>idlVerbose</code>	Displays verbose information for IDL generation.
<code>idlNoValueTypes</code>	Does not generate valuetypes and the methods/attributes that contain them.
<code>idlNoAbstractInterfaces</code>	Does not generate abstract interfaces and methods/attributes that contain them.
<code>idlFactories</code>	Generates factory methods for valuetypes.
<code>idlVisibroker</code>	Generates IDL somewhat compatible with Visibroker 4.5 C++.
<code>idlOrbix</code>	Generates IDL somewhat compatible with Orbix 2000 2.0 C++.
<code>idlDirectory <dir></code>	Specifies the directory where IDL files will be created (default: target directory or JAR)
<code>idlMethodSignatures <></code>	Specifies the method signatures used to trigger IDL code generation.
<code>iiop</code>	Generates CORBA stubs for EJBs.
<code>iiopDirectory <dir></code>	Specifies the directory where IIOP stub files will be written (default: target directory or JAR)
<code>keepgenerated</code>	Keeps the generated <code>.java</code> files.
<code>librarydir</code>	Specifies a directory of shared Java EE libraries to add to the classpath. See Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."
<code>compiler <java.jdt></code>	Selects the Java compiler to use. Defaults to JDT.
<code>debug</code>	Compiles debugging information into a class file.
<code>optimize</code>	Compiles with optimization on.
<code>nowarn</code>	Compiles without warnings.
<code>verbose</code>	Compiles with verbose output.

Table 5–3 (Cont.) wlapcc Ant Task Attributes

Option	Description
deprecation	Warns about deprecated calls.
normi	Passes flags through to Symantec's sj.
runtimeflags	Passes flags through to Java runtime
classpath <path>	Selects the classpath to use during compilation.
clientJarOutputDir <dir>	Specifies a directory to place generated client jar files. If not set, generated jar files are placed into the same directory location where the JVM is running.
advanced	Prints advanced usage options.

5.2.2 wlapcc Ant Task Syntax

The basic syntax for using the wlapcc Ant task determines the destination source directory location. This directory contains the files to be compiled by wlapcc.

```
<wlapcc source="${dest.dir}" />
```

The following is an example of a wlapcc Ant task command that invokes two options (idl and idlOrverWrite) from [Table 5–3](#).

```
<wlapcc source="${dest.dir}" idl="true" idlOrverWrite="true" />
```

5.2.3 Syntax Differences between appc and wlapcc

There are some syntax differences between appc and wlapcc. For appc, the presence of a flag in the command is a Boolean. For wlapcc, the presence of a flag in the command means that the argument is required.

To illustrate, the following are examples of the same command, the first being an appc command and the second being a wlapcc command:

```
java weblogic.appc -idl foo.ear
<wlapcc source="${dest.dir}" idl="true"/>
```

5.2.4 weblogic.appc Reference

The following sections describe how to use the command-line version of the appc compiler. The weblogic.appc command-line compiler reports any warnings or errors encountered in the descriptors and compiles all of the relevant modules into an EAR file, which can be deployed to WebLogic Server.

5.2.5 weblogic.appc Syntax

Use the following syntax to run appc:

```
prompt>java weblogic.appc [options] <ear, jar, or war file or directory>
```

5.2.6 weblogic.appc Options

The following are the available appc options:

Option	Description
-print	Prints the standard usage message.
-version	Prints appc version information.

Option	Description
-output <file>	Specifies an alternate output archive or directory. If not set, the output is placed in the source archive or directory.
-forceGeneration	Forces generation of EJB and JSP classes. Without this flag, the classes may not be regenerated (if determined to be unnecessary).
-library <file[@name=<string>][@libspecver=<version>][@libimplver=<version string>]>	A comma-separated list of shared Java EE libraries. Optional name and version string information must be specified in the format described in Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application" .
-writeInferredDescriptors	Specifies that the application or module contains deployment descriptors with annotation information.
-lineNumbers	Adds line numbers to generated class files to aid in debugging.
-basicClientJar	Does not include deployment descriptors in client JARs generated for EJBs.
-idl	Generates IDL for EJB remote interfaces.
-idlOverwrite	Always overwrites existing IDL files.
-idlVerbose	Displays verbose information for IDL generation.
-idlNoValueTypes	Does not generate valuetypes and the methods/attributes that contain them.
-idlNoAbstractInterfaces	Does not generate abstract interfaces and methods/attributes that contain them.
-idlFactories	Generates factory methods for valuetypes.
-idlVisibroker	Generates IDL somewhat compatible with Visibroker 4.5 C++.
-idlOrbix	Generates IDL somewhat compatible with Orbix 2000 2.0 C++.
-idlDirectory <dir>	Specifies the directory where IDL files will be created (default: target directory or JAR)
-idlMethodSignatures <>	Specifies the method signatures used to trigger IDL code generation.
-iiop	Generates CORBA stubs for EJBs.
-iiopDirectory <dir>	Specifies the directory where IIOP stub files will be written (default: target directory or JAR)
-keepgenerated	Keeps the generated .java files.
-compiler <javac>	Selects the Java compiler to use.
-g	Compiles debugging information into a class file.
-O	Compiles with optimization on.
-nowarn	Compiles without warnings.
-verbose	Compiles with verbose output.
-deprecation	Warns about deprecated calls.
-normi	Passes flags through to Symantec's sj.
-J<option>	Passes flags through to Java runtime.
-classpath <path>	Selects the classpath to use during compilation.

Option	Description
-clientJarOutputDir <dir>	Specifies a directory to place generated client jar files. If not set, generated jar files are placed into the same directory location where the JVM is running.
-advanced	Prints advanced usage options.

Deploying and Packaging from a Split Development Directory

This chapter describes how to deploy WebLogic Server Java EE applications using the WebLogic split development directory environment.

This chapter includes the following sections:

- [Section 6.1, "Deploying Applications Using wldeploy"](#)
- [Section 6.2, "Packaging Applications Using wlpkgage"](#)

6.1 Deploying Applications Using wldeploy

The `wldeploy` task provides an easy way to deploy directly from the split development directory. `wlcompile` provides most of the same arguments as the `weblogic.Deployer` directory. To deploy from a split development directory, you simply identify the build directory location as the deployable files, as in:

```
<wldeploy user="${user}" password="${password}"  
  action="deploy" source="${dest.dir}"  
  name="helloWorldEar" />
```

The above task is automatically created when you use `weblogic.BuildXMLGen` to create the `build.xml` file.

See [Appendix B, "wldeploy Ant Task Reference,"](#) for a complete command reference.

6.2 Packaging Applications Using wlpkgage

The `wlpkgage` Ant task uses the contents of both the source and build directories to create either a deployable archive file (.EAR file), or an exploded archive directory representing the enterprise application (exploded .EAR directory). Use `wlpkgage` when you want to deliver your application to another group or individual for evaluation, testing, performance profiling, or production deployment.

6.2.1 Archive versus Exploded Archive Directory

For production purposes, it is convenient to deploy enterprise applications in exploded (unarchived) directory format. This applies also to standalone Web applications, EJBs, and connectors packaged as part of an enterprise application. Using this format allows you to update files directly in the exploded directory rather than having to unarchive, edit, and rearchive the whole application. Using exploded archive directories also has other benefits, as described in [Deployment Archive Files](#)

Versus Exploded Archive Directories in *Deploying Applications to Oracle WebLogic Server*.

You can also package applications in a single archived file, which is convenient for packaging modules and applications for distribution. Archive files are easier to copy, they use up fewer file handles than an exploded directory, and they can save disk space with file compression.

The Java classloader can search for Java class files (and other file types) in a JAR file the same way that it searches a directory in its classpath. Because the classloader can search a directory or a JAR file, you can deploy Java EE modules on WebLogic Server in either a JAR (archived) file or an exploded (unarchived) directory.

6.2.2 wpackage Ant Task Example

In a production environment, use the wpackage Ant task to package your split development directory application as a traditional EAR file that can be deployed to WebLogic Server. Continuing with the MedRec example, you would package your application as follows:

```
<wpackage tofile="\physicianEAR\physicianEAR.ear"
          srcdir="\physicianEAR"
          destdir="\build\physicianEAR" />
<wpackage todir="\physicianEAR\explodedphysicianEar"
          srcdir="\src\physicianEAR"
          destdir="\build\physicianEAR" />
```

6.2.3 wpackage Ant Task Attribute Reference

The following table describes the attributes of the wpackage Ant task.

Table 6–1 Attributes of the wpackage Ant Task

Attribute	Description	Data Type	Required?
tofile	Name of the EAR archive file into which the wpackage Ant task packages the split development directory application.	String	You must specify one of the following two attributes: tofile or todir.
todir	Name of an exploded directory into which the wpackage Ant task packages the split development directory application.	String	You must specify one of the following two attributes: tofile or todir.
srcdir	Specifies the source directory of your split development directory application. The source directory contains all editable files for your project—Java source files, editable descriptor files, JSPs, static content, and so forth.	String	Yes.
destdir	Specifies the build directory of your split development directory application. It is assumed that you have already executed the wcompile Ant task against the source directory to generate the needed components into the build directory; these components include compiled Java classes and generated deployment descriptors.	String	Yes.

Developing Applications for Production Redeployment

This chapter describes how to program and maintain applications with WebLogic Server using the production redeployment strategy.

This chapter includes the following sections:

- [Section 7.1, "What is Production Redeployment?"](#)
- [Section 7.2, "Supported and Unsupported Application Types"](#)
- [Section 7.3, "Programming Requirements and Conventions"](#)
- [Section 7.4, "Assigning an Application Version"](#)
- [Section 7.5, "Upgrading Applications to Use Production Redeployment"](#)
- [Section 7.6, "Accessing Version Information"](#)

7.1 What is Production Redeployment?

Production redeployment enables an administrator to redeploy a new version of an application in a production environment without stopping the deployed application or otherwise interrupting the application's availability to clients. Production redeployment works by deploying a new version of an updated application alongside an older version of the same application. WebLogic Server automatically manages client connections so that only new client requests are directed to the new version. Clients already connected to the application during the redeployment continue to use the older, retiring version of the application until they complete their work.

See "Using Production Redeployment to Upgrade Applications" for more information.

7.2 Supported and Unsupported Application Types

Production redeployment only supports HTTP clients and RMI clients. Your development and design team must ensure that applications using production redeployment are not accessed by an unsupported client. WebLogic Server does not detect when unsupported clients access the application, and does not preserve unsupported client connections during production redeployment.

Enterprise applications can contain any of the supported Java EE module types. Enterprise applications can also include application-scoped JMS and JDBC modules.

If an enterprise application includes a JCA resource adapter module, the module:

- Must be JCA 1.5 compliant

- Must implement the `weblogic.connector.extensions.Suspendable` interface
- Must be used in an application-scoped manner, having `enable-access-outside-app` set to `false` (the default value).

Before resource adapters in a newer version of the EAR are deployed, resource adapters in the older application version receive a callback. WebLogic Server then deploys the newer application version and retires the entire older version of the EAR.

For a complete list of production redeployment requirements for resource adapters, see "Production Redeployment" in *Developing Resource Adapters for Oracle WebLogic Server*.

7.2.1 Additional Application Support

Additional production redeployment support is provided for enterprise applications that are accessed by inbound JMS messages from a global JMS destination, and that use one or more message-driven beans as consumers. For this type of application, WebLogic Server suspends message-driven beans in the older, retiring application version before deploying message-driven beans in the newer version. Production redeployment is not supported with JMS consumers that use the JMS API for global JMS destinations. If the message-driven beans need to receive all messages published from topics, including messages published while bean are suspended, use durable subscribers.

7.3 Programming Requirements and Conventions

WebLogic Server performs production redeployment by deploying two instances of an application simultaneously. You must observe certain programming conventions to ensure that multiple instances of the application can co-exist in a WebLogic Server domain. The following sections describe each programming convention required for using production redeployment.

7.3.1 Applications Should Be Self-Contained

As a best practice, applications that use the in-place redeployment strategy should be self-contained in their use of resources. This means you should generally use application-scoped JMS and JDBC resources, rather than global resources, whenever possible for versioned applications.

If an application must use a global resource, you must ensure that the application supports safe, concurrent access by multiple instances of the application. This same restriction also applies if the application uses external (separately-deployed) applications, or uses an external property file. WebLogic Server does not prevent the use of global resources with versioned applications, but you must ensure that resources are accessed in a safe manner.

Looking up a global JNDI resource from within a versioned application results in a warning message. To disable this check, set the JNDI environment property `weblogic.jndi.WLContext.ALLOW_GLOBAL_RESOURCE_LOOKUP` to `true` when performing the JNDI lookup.

Similarly, looking up an external application results in a warning unless you set the JNDI environment property, `weblogic.jndi.WLContext.ALLOW_EXTERNAL_APP_LOOKUP`, to `true`.

7.3.2 Versioned Applications Access the Current Version JNDI Tree by Default

WebLogic Server binds application-scoped resources, such as JMS and JDBC application modules, into a local JNDI tree available to the application. As with non-versioned applications, versioned applications can look up application-scoped resources directly from this local tree. Application-scoped JMS modules can be accessed via any supported JMS interfaces, such as the JMS API or a message-driven bean.

Application modules that are bound to the global JNDI tree should be accessed only from within the same application version. WebLogic Server performs version-aware JNDI lookups and bindings for global resources deployed in a versioned application. By default, an internal JNDI lookup of a global resource returns bindings for the same version of the application.

If the current version of the application cannot be found, you can use the JNDI environment property `weblogic.jndi.WLContext.RELAX_VERSION_LOOKUP` to return bindings from the currently active version of the application, rather than the same version.

Note:: Set `weblogic.jndi.WLContext.RELAX_VERSION_LOOKUP` to `true` only if you are certain that the newer and older version of the resource that you are looking up are compatible with one another.

7.3.3 Security Providers Must Be Compatible

Any security provider used in the application must support the WebLogic Server application versioning SSPI. The default WebLogic Server security providers for authorization, role mapping, and credential mapping support the application versioning SSPI.

7.3.4 Applications Must Specify a Version Identifier

In order to use production redeployment, both the current, deployed version of the application and the updated version of the application must specify unique version identifiers. See [Section 7.4, "Assigning an Application Version"](#).

7.3.5 Applications Can Access Name and Identifier

Versioned applications can programmatically obtain both an application name, which remains constant across different versions, and an application identifier, which changes to provide a unique label for different versions of the application. Use the application name for basic display or error messages that refer to the application's name irrespective of the deployed version. Use the application ID when the application must provide unique identifier for the deployed version of the application. See [Section 7.6, "Accessing Version Information"](#) for more information about the MBean attributes that provide the name and identifier.

7.3.6 Client Applications Use Same Version when Possible

As described in [Section 7.1, "What is Production Redeployment?"](#), WebLogic Server attempts to route a client application's requests to the same version of the application until all of the client's in-progress work has completed. However, if an application version is retired using a timeout period, or is undeployed, the client's request will be routed to the active version of the application. In other words, a client's association with a given version of an application is maintained only on a "best-effort basis."

This behavior can be problematic for client applications that recursively access other applications when processing requests. WebLogic Server attempts to dispatch requests to the same versions of the recursively-accessed applications, but cannot guarantee that an intermediate application version is not undeployed manually or after a timeout period. If you have a group of related applications with strict version requirements, Oracle recommends packaging all of the applications together to ensure version consistency during production redeployment.

7.4 Assigning an Application Version

Oracle recommends that you specify the version identifier in the `MANIFEST.MF` of the application, and automatically increment the version each time a new application is released for deployment. This ensures that production redeployment is always performed when the administrator or deployer redeploys the application.

For testing purposes, a deployer can also assign a version identifier to an application during deployment and redeployment. See "Assigning a Version Identifier During Deployment and Redeployment" in *Deploying Applications to Oracle WebLogic Server*.

7.4.1 Application Version Conventions

WebLogic Server obtains the application version from the value of the `Weblogic-Application-Version` property in the `MANIFEST.MF` file. The version string can be a maximum of 215 characters long, and must consist of valid characters as identified in [Table 7-1](#).

Table 7-1 Valid and Invalid Characters

Valid ASCII Characters	Invalid Version Constructs
a-z	..
A-Z	.
0-9	
period ("."), underscore ("_"), or hyphen ("-") in combination with other characters	

For example, the following manifest file content describes an application with version "v920.beta":

```
Manifest-Version: 1.0
Created-By: 1.4.1_05-b01 (Sun Microsystems Inc.)
Weblogic-Application-Version: v920.beta
```

7.5 Upgrading Applications to Use Production Redeployment

If you are upgrading applications for deployment to WebLogic Server 9.2 or later, note that the `Name` attribute retrieved from `AppDeploymentMBean` now returns a unique application identifier consisting of both the deployed application name and the application version string. Applications that require only the deployed application name must use the new `ApplicationName` attribute instead of the `Name` attribute. Applications that require a unique identifier can use either the `Name` or `ApplicationIdentifier` attribute, as described in [Section 7.6, "Accessing Version Information"](#).

7.6 Accessing Version Information

Your application code can use new MBean attributes to retrieve version information for display, logging, or other uses. The following table describes the read-only attributes provided by `ApplicationMBean`.

Table 7-2 Read-Only Version Attributes in `ApplicationMBean`

Attribute Name	Description
<code>ApplicationName</code>	A String that represents the deployment name of the application
<code>VersionIdentifier</code>	A String that uniquely identifies the current application version across all versions of the same application
<code>ApplicationIdentifier</code>	A String that uniquely identifies the current application version across all deployed applications and versions

`ApplicationRuntimeMBean` also provides version information in the new read-only attributes described in the following table.

Table 7-3 Read-Only Version Attributes in `ApplicationRuntimeMBean`

Attribute Name	Description
<code>ApplicationName</code>	A String that represents the deployment name of the application
<code>ApplicationVersion</code>	A string that represents the version of the application.
<code>ActiveVersionState</code>	<p>An integer that indicates the current state of the active application version. Valid states for an active version are:</p> <ul style="list-style-type: none"> ■ <code>ACTIVATED</code>—indicates that one or more modules of the application are active and available for processing new client requests. ■ <code>PREPARED</code>—indicates that WebLogic Server has prepared one or more modules of the application, but that it is not yet active. ■ <code>UNPREPARED</code>—indicates that no modules of the application are prepared or active. <p>See the <i>Java API Reference for Oracle WebLogic Server</i> for more information.</p> <p>Note that the currently active version does not always correspond to the last-deployed version, because the administrator can reverse the production redeployment process. See "Rolling Back the Production Redeployment Process" in <i>Deploying Applications to Oracle WebLogic Server</i>.</p>

Using Java EE Annotations and Dependency Injection

This chapter describes Java EE MetaData annotations and dependency injection (DI).

This chapter includes the following sections:

- [Section 8.1, "Annotation Processing"](#)
- [Section 8.2, "Dependency Injection of Resources"](#)
- [Section 8.3, "Standard JDK Annotations"](#)
- [Section 8.4, "Standard Security-Related JDK Annotations"](#)

8.1 Annotation Processing

With Java EE annotations, the standard `application.xml` and `web.xml` deployment descriptors are optional. The Java EE programming model uses the JDK annotations feature for Web containers, such as EJBs, servlets, Web applications, and JSPs (see <http://docs.oracle.com/javaee/6/api/>).

Annotations simplify the application development process by allowing developers to specify within the Java class itself how the application component behaves in the container, requests for dependency injection, and so on. Annotations are an alternative to deployment descriptors that were required by older versions of enterprise applications (Java EE 1.4 and earlier).

8.1.1 Annotation Parsing

The application components can use annotations to define their needs. Annotations reduce or eliminate the need to deal with deployment descriptors. Annotations simplify the development of application components. The deployment descriptor can still override values defined in the annotation. One usage of annotations is to define fields or methods that need Dependency Injection (DI). Annotations are defined on the POJO (plain old Java object) component classes like the EJB or the servlet.

An annotation on a field or a method can declare that fields/methods need injection, as described in [Section 8.2, "Dependency Injection of Resources"](#). Annotations may also be applied to the class itself. The class-level annotations declare an entry in the application component's environment but do not cause the resource to be injected. Instead, the application component is expected to use JNDI or component context lookup method to lookup the entry. When the annotation is applied to the class, the JNDI name and the environment entry type must be specified explicitly.

8.1.2 Deployment View of Annotation Configuration

The Java EE Deployment API [JSR88] provides a way for developers to examine deployment descriptors. For example, consider an EJB Module that has no deployment descriptors. Assuming that it has some classes that have been declared as EJBs using annotations, a user of Session Helper will still be able to deal with the module as if it had the deployment descriptor. So the developer can modify the configuration information and it will be written out in a deployment plan. During deployment, such a plan will be honored and will override information from annotations.

8.1.3 Compiling Annotated Classes

The WebLogic Server utility `appc` (and its Ant equivalent `wlappc`) and `Appmerge` support metadata annotations. The `appmerge` and `appc` utilities take an application or module as inputs and process them to produce an output application or module respectively. When used with `-writeInferredDescriptors` flag, the output application/module will contain deployment descriptors with annotation information. The descriptors will also have the `metadata-complete` attribute set to `true`, as no annotation processing needs to be done if the output application or module is deployed directly. However, setting of `metadata-complete` attribute to `true` will also restrict `appmerge` and `appc` from processing annotations in case these tools are invoked on a previously processed application or module.

The original descriptors must be preserved in such cases to with an `.orig` suffix. If a developer wants to reapply annotation processing on the output application, they must restore the descriptors and use the `-writeInferredDescriptors` flag again. If `appmerge` or `appc` is used with `-writeInferredDescriptors` on an enterprise application for which no standard deployment descriptor exists, the descriptor will be generated and written out based on the inference rules in the Java EE specification.

For more information on using `appc`, see [Section 5.2.4, "weblogic.appc Reference"](#). For more information on using `appmerge`, see [Section 12.5, "Using weblogic.appmerge to Merge Libraries"](#).

8.1.4 Dynamic Annotation Updates

Deployed modules can be updated using `update` deployment operation. If such an update has changes to deployment descriptor or updated classes, the container must consider annotation information again while processing the new deployment descriptor.

Containers use the descriptor framework's two-phase update mechanism to check the differences between the current and proposed descriptors. This mechanism also informs the containers about any changes in the non-dynamic properties. The containers then deal with such non-dynamic changes in their own specific ways. The container must perform annotation processing on the proposed descriptor to make sure that it is finding the differences against the right reference.

Similarly, some of the classes from a module could be updated during an update operation. If the container knows that these classes could affect configuration information through annotations, it makes sure that nothing has changed.

8.2 Dependency Injection of Resources

Dependency injection (DI) allows application components to declare dependencies on external resources and configuration parameters via annotations. The container reads these annotations and injects resources or environment entries into the application

components. Dependency injection is simply an easier-to-program alternative to using the `javax` interfaces or JNDI APIs to look up resources.

A field or a method of an application component can be annotated with the `@Resource` annotation. Note that the container will unbox the environment entry as required to match it to a primitive type used for the injection field or method. [Example 8-1](#) illustrates how an application component uses the `@Resource` annotation to declare environment entries.

Example 8-1 Dependency Injection of Environment Entries

```
// fields

// The maximum number of tax exemptions, configured by the Deployer.
@Resource int maxExemptions;
// The minimum number of tax exemptions, configured by the Deployer.
@Resource int minExemptions;

...
}
```

In the above code the `@Resource` annotation has not specified a name; therefore, the container would look for an `env-entry` name called `<class-name>/maxExemptions` and inject the value of that entry into the `maxExemptions` variable. The field or method may have any access qualifier (`public`, `private`, etc.). For all classes except application client main classes, the fields or methods must not be static. Because application clients use the same life cycle as Java EE applications, no instance of the application client main class is created by the application client container. Instead, the static main method is invoked. To support injection for the application client main class, the fields or methods annotated for injection must be static.

8.2.1 Application Life Cycle Annotation Methods

An application component may need to perform initialization of its own after all resources have been injected. To support this case, one method of the class can be annotated with the `@PostConstruct` annotation. This method will be called after all injections have occurred and before the class is put into service. This method will be called even if the class doesn't request any resources to be injected. Similarly, for classes whose life cycle is managed by the container, the `@PreDestroy` annotation can be applied to one method that will be called when the class is taken out of service and will no longer be used by the container. Each class in a class hierarchy may have `@PostConstruct` and `@PreDestroy` methods.

The order in which the methods are called matches the order of the class hierarchy, with methods on a superclass being called before methods on a subclass. From the Java EE side only the application client container is involved in invoking these life cycle methods for Java EE clients. The life cycle methods for Java EE clients must be static. The Java EE client just supports the `@PostConstruct` callback.

8.3 Standard JDK Annotations

This section provides reference information about the following annotations:

- [Section 8.3.1, "javax.annotation.PostConstruct"](#)
- [Section 8.3.2, "javax.annotation.PreDestroy"](#)
- [Section 8.3.3, "javax.annotation.Resource"](#)

- [Section 8.3.4, "javax.annotation.Resources"](#)

For detailed information about EJB-specific annotations for WebLogic Server Enterprise JavaBeans, see *Developing Enterprise JavaBeans for Oracle WebLogic Server*.

For detailed information about Web component-specific annotations WebLogic Server applications, see "WebLogic Annotation for Web Components" in *Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server*.

8.3.1 `javax.annotation.PostConstruct`

Target: Method

Specifies the life cycle callback method that the application component should execute before the first business method invocation and after dependency injection is done to perform any initialization. This method will be called after all injections have occurred and before the class is put into service. This method will be called even if the class doesn't request any resources to be injected.

You must specify a `@PostConstruct` method in any component that includes dependency injection.

Only one method in the component can be annotated with this annotation.

The method annotated with `@PostConstruct` must follow these requirements:

- The method must not have any parameters, except in the case of EJB interceptors, in which case it takes a `javax.interceptor.InvocationContext` object as defined by the EJB specification.
- The return type of the method must be `void`.
- The method must not throw a checked exception.
- The method may be `public`, `protected`, `package private` or `private`.
- The method must not be `static` except for the application client.
- The method may be `final` or non-`final`, except in the case of EJBs where it must be non-`final`.
- If the method throws an unchecked exception, the class must not be put into service. In the case of EJBs, the method annotated with `PostConstruct` can handle exceptions and cleanup before the bean instance is discarded.

This annotation does not have any attributes.

8.3.2 `javax.annotation.PreDestroy`

Target: Method

Specifies the life cycle callback method that signals that the application component is about to be destroyed by the container. You typically apply this annotation to methods that release resources that the class has been holding.

Only one method in the bean class can be annotated with this annotation.

The method annotated with `@PreDestroy` must follow these requirements:

- The method must not have any parameters, except in the case of EJB interceptors, in which case it takes a `javax.interceptor.InvocationContext` object as defined by the EJB specification.
- The return type of the method must be `void`.

- The method must not throw a checked exception.
- The method may be `public`, `protected`, `package private` or `private`.
- The method must not be `static` except for the application client.
- The method may be `final` or non-`final`, except in the case of EJBs where it must be non-`final`.
- If the method throws an unchecked exception, the class must not be put into service. In the case of EJBs, the method annotated with `PostConstruct` can handle exceptions and cleanup before the bean instance is discarded.

This annotation does not have any attributes.

8.3.3 `javax.annotation.Resource`

Target: Class, Method, Field

Specifies a dependence on an external resource, such as a JDBC data source or a JMS destination or connection factory.

If you specify the annotation on a field or method, the application component injects an instance of the requested resource into the bean when the bean is initialized. If you apply the annotation to a class, the annotation declares a resource that the component will look up at runtime.

Attributes

Table 8–1 Attributes of the `javax.annotation.Resource` Annotation

Name	Description	Data Type	Required?
name	Specifies the JNDI name of the resource. If you apply the <code>@Resource</code> annotation to a field, the default value of the <code>name</code> attribute is the field name, qualified by the class name. If you apply it to a method, the default value is the component property name corresponding to the method, qualified by the class name. If you apply the annotation to class, there is no default value and thus you are required to specify the attribute.	String	No
type	Specifies the Java data type of the resource. If you apply the <code>@Resource</code> annotation to a field, the default value of the <code>type</code> attribute is the type of the field. If you apply it to a method, the default is the type of the component property. If you apply it to a class, there is no default value and thus you are required to specify this attribute.	Class	No
authentication Type	Specifies the authentication type to use for the resource. Valid values for this attribute are: <ul style="list-style-type: none"> ■ <code>AuthenticationType.CONTAINER</code> ■ <code>AuthenticationType.APPLICATION</code> Default value is <code>AuthenticationType.CONTAINER</code>	Authentication Type	No

Table 8–1 (Cont.) Attributes of the `javax.annotation.Resource` Annotation

Name	Description	Data Type	Required?
shareable	Indicates whether a resource can be shared between this component and other components. Valid values for this attribute are <code>true</code> and <code>false</code> . Default value is <code>true</code> .	Boolean	No
mappedName	Specifies a WebLogic Server-specific name to which the component reference should be mapped. However, if you do not specify a JNDI name in the WebLogic deployment descriptor file, then the value of <code>mappedName</code> will always be used as the JNDI name to look up. For example: <pre>@Resource(mappedName = "http://www.bea.com"); URL url; @Resource(mappedName="customerDB") DataSource db; @Resource(mappedName = "jms/ConnectionFactory") ConnectionFactory connectionFactory; @Resource(mappedName = "jms/Queue") Queue queue;</pre> In other words, <code>MappedName</code> is honored as JNDI name only when there is no JNDI name specified elsewhere, typically in the WebLogic deployment descriptor file.	String	No
description	Specifies a description of the resource.	String	No

8.3.4 `javax.annotation.Resources`

Target: Class

Specifies an array of `@Resource` annotations. Since repeated annotations are not allowed, the `Resources` annotation acts as a container for multiple resource declarations.

Attributes

Table 8–2 Attributes of the `javax.annotation.Resources` Annotation

Name	Description	Data Type	Required?
value	Specifies the array of <code>@Resource</code> annotations.	<code>Resource[]</code>	Yes

8.4 Standard Security-Related JDK Annotations

This section provides reference information about the following annotations:

- [Section 8.4.1, "javax.annotation.security.DeclareRoles"](#)
- [Section 8.4.2, "javax.annotation.security.DenyAll"](#)
- [Section 8.4.3, "javax.annotation.security.PermitAll"](#)
- [Section 8.4.4, "javax.annotation.security.RolesAllowed"](#)
- [Section 8.4.5, "javax.annotation.security.RunAs"](#)

8.4.1 `javax.annotation.security.DeclareRoles`

Target: Class

Defines the security roles that will be used in the Java EE container.

You typically use this annotation to define roles that can be tested from within the methods of the annotated class, such as using the `isUserInRole` method. You can also use the annotation to explicitly declare roles that are implicitly declared if you use the `@RolesAllowed` annotation on the class or a method of the class.

You create security roles in WebLogic Server using the WebLogic Server Administration Console. For details, see "Manage Security Roles".

Attributes

Table 8–3 *Attributes of the `javax.annotation.security.DeclareRoles` Annotation*

Name	Description	Data Type	Required?
value	Specifies an array of security roles that will be used in the Java EE container.	String[]	Yes

8.4.2 `javax.annotation.security.DenyAll`

Target: Method

Specifies that no security role is allowed to access the annotated method, or in other words, the method is excluded from execution in the Java EE container.

This annotation does not have any attributes.

8.4.3 `javax.annotation.security.PermitAll`

Target: Method

Specifies that all security roles currently defined for WebLogic Server are allowed to access the annotated method.

This annotation does not have any attributes.

8.4.4 `javax.annotation.security.RolesAllowed`

Target: Class, Method

Specifies the list of security roles that are allowed to access methods in the Java EE container.

If you specify it at the class-level, then it applies to all methods in the application component. If you specify it at the method-level, then it only applies to that method. If you specify the annotation at both the class- and method-level, the method value overrides the class value.

You create security roles in WebLogic Server using the WebLogic Server Administration Console. For details, see "Manage Security Roles".

Attributes

Table 8–4 *Attributes of the `javax.annotation.security.RolesAllowed` Annotation*

Name	Description	Data Type	Required?
value	List of security roles that are allowed to access methods of the Java EE container.	String[]	Yes

8.4.5 javax.annotation.security.RunAs

Target: Class

Specifies the security role which actually executes the Java EE container.

The security role must exist in the WebLogic Server security realm and map to a user or group. For details, see "Manage Security Roles".

Attributes

Table 8–5 *Attributes of the javax.annotation.security.RunAs Annotation*

Name	Description	Data Type	Required?
value	Specifies the security role that the Java EE container should run as.	String	Yes

Using Contexts and Dependency Injection for the Java EE Platform

WebLogic Server provides an implementation of the Contexts and Dependency Injection (CDI) specification. The CDI specification defines a set of services for using injection to specify dependencies in an application. CDI provides contextual life cycle management of beans, type-safe injection points, a loosely coupled event framework, loosely coupled interceptors and decorators, alternative implementations of beans, bean navigation through the Unified Expression Language (EL), and a service provider interface (SPI) that enables CDI extensions to support third-party frameworks or future Java EE components.

The following sections explain how to use CDI for the Java EE platform in your applications:

- [Section 9.1, "About CDI for the Java EE Platform"](#)
- [Section 9.2, "Defining a Managed Bean"](#)
- [Section 9.3, "Injecting a Bean"](#)
- [Section 9.4, "Defining the Scope of a Bean"](#)
- [Section 9.5, "Overriding the Scope of a Bean at the Point of Injection"](#)
- [Section 9.6, "Using Qualifiers"](#)
- [Section 9.7, "Providing Alternative Implementations of a Bean Type"](#)
- [Section 9.8, "Applying a Scope and Qualifiers to a Session Bean"](#)
- [Section 9.9, "Using Producer Methods, Disposer Methods, and Producer Fields"](#)
- [Section 9.10, "Initializing and Preparing for the Destruction of a Managed Bean"](#)
- [Section 9.11, "Intercepting Method Invocations and Life Cycle Events of Bean Classes"](#)
- [Section 9.12, "Decorating a Managed Bean Class"](#)
- [Section 9.13, "Assigning an EL Name to a CDI Bean Class"](#)
- [Section 9.14, "Defining and Applying Stereotypes"](#)

- [Section 9.16, "Injecting a Predefined Bean"](#)
- [Section 9.17, "Injecting and Qualifying Resources"](#)
- [Section 9.18, "Using CDI With JCA Technology"](#)
- [Section 9.19, "Configuring a CDI Application"](#)

- [Section 9.20, "Supporting Third-Party Portable Extensions"](#)
- [Section 9.21, "Enabling and Disabling Implicit Bean Discovery"](#)

9.1 About CDI for the Java EE Platform

CDI is specified by Java Specification Request (JSR) 346: Contexts and Dependency Injection for the Java EE platform. This specification was formerly called Web Beans. CDI uses the following related specifications:

- JSR 330: Dependency Injection for Java
- Java EE 7 Managed Beans Specification, which is a part of JSR 342: Java Platform, Enterprise Edition 7 (Java EE 7) Specification
- Interceptors specification, which is a part of JSR 345: Enterprise JavaBeans 3.2 specification

CDI provides the following features:

- **Contexts** – This feature enables you to bind the life cycle and interactions of stateful components to well-defined but extensible life cycle contexts.
- **Dependency injection** – This feature enables you to inject components into an application in a type-safe way and to choose at deployment time which implementation of a particular interface to inject.

CDI is integrated with the major component technologies in Java EE, namely:

- Servlets
- JavaServer Pages (JSP)
- JavaServer Faces (JSF)
- Enterprise JavaBeans (EJB)
- Java EE Connector architecture (JCA)
- Web services

Such integration enables standard Java EE objects, such as Servlets and EJB components, to use CDI injection for dependencies. CDI injection simplifies, for example, the use of managed beans with JSF technology in Web applications.

For more information, see [Introduction to Contexts and Dependency Injection for the Java EE Platform](#) in the *Java EE 7 Tutorial*.

9.1.1 CDI 1.1 Examples

Oracle provides Java EE 7 examples that demonstrate new features in CDI 1.1, such as:

- **CDI Events CDI Sample Application** – Demonstrates how beans can interact in a decoupled fashion with no compile-time dependencies between the interacting beans.
- **CDI Transactional Annotation** – Demonstrates how to inject a bean annotated with the `@Transactional` annotation, which provides an application with the ability to declaratively control transaction boundaries on CDI managed beans.
- **CDI Transaction Scoped API** – Demonstrate how the `@TransactionScoped` annotation provides the ability to specify a standard CDI scope to define bean instances whose life cycle is scoped to the currently active JTA transaction.

For more information, see the CDI 1.1 examples in the WebLogic Server distribution kit: `EXAMPLES_HOME/examples/src/examples/javaee7/cdi` where `EXAMPLES_HOME` represents the directory in which the WebLogic Server code examples are configured. For more information, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

9.1.2 CDI 1.0 Example

A Java EE 6 example that shows how to use CDI is provided in the `cdi` sample application, which is installed in `EXAMPLES_HOME/examples/src/examples/javaee6/cdi`, where `EXAMPLES_HOME` represents the directory in which you installed WebLogic Server. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

9.2 Defining a Managed Bean

A bean is a source of the objects that CDI can create and manage. For more information, see About Beans in *The Java EE 7 Tutorial*.

A managed bean is the basic component in a CDI application and defines the beans that CDI can create and manage. To define a managed bean, define a top-level plain old Java object (POJO) class that meets either of the following conditions:

- The class is defined to be a managed bean by any other Java EE specification.
- The class meets all of the conditions that are required by JSR 346 as listed in About Managed CDI Beans in *The Java EE 7 Tutorial*.

Note: No special declaration, such as an annotation, is required to define a managed bean. To make the managed beans of an application available for injection, you must configure the application as explained in [Section 9.19, "Configuring a CDI Application."](#)

9.3 Injecting a Bean

To use the beans that you define, inject them into another bean that an application such as a JavaServer Faces application can use. For more information, see Injecting Beans in *The Java EE 7 Tutorial*.

CDI ensures type-safe injection of beans by selecting the bean class on the basis of the Java type that is specified in the injection point, not the bean name. CDI also determines where to inject a bean from the Java type in the injection point.

In this respect, CDI bean injection is different than the resource injection that was introduced in the Java EE 5 specification, which selects the resource to inject from the string name of the resource. For example, a data source that is injected with the `javax.annotation.Resource` annotation is identified by its string name.

To inject a bean, obtain an instance of the bean by creating an injection point in the class that is to use the injected bean. Create the injection point by annotating one of the following program elements with the `javax.inject.Inject` annotation:

- An instance class field
- An initializer method parameter
- A bean constructor parameter

[Example 9-1](#) shows how to use the `@Inject` annotation to inject a bean into another bean.

Example 9-1 Injecting a Bean into Another Bean

This example annotates an instance class field to inject an instance of the bean class `Greeting` into the class `Printer`.

```
import javax.inject.Inject;
...
public class Printer {
    @Inject Greeting greeting;
    ...
}
```

9.4 Defining the Scope of a Bean

The scope of a bean defines the duration of a user's interaction with an application that uses the bean. To enable a Web application to use a bean that injects another bean class, the bean must be able to hold state over the duration of the user's interaction with the application.

To define the scope of a bean, annotate the class declaration of the bean with the scope. The `javax.enterprise.context` package defines the following scopes:

- `@RequestScoped`
- `@SessionScoped`
- `@ApplicationScoped`
- `@ConversationScoped`
- `@Dependent`

For information about these scopes, see *Using Scopes* in *The Java EE 7 Tutorial*.

If you do not define the scope of a bean, the scope of the bean is `@Dependent` by default. The `@Dependent` scope specifies that the bean's life cycle is the life cycle of the object into which the bean is injected.

The predefined scopes **except** `@Dependent` are contextual scopes. CDI places beans of contextual scope in the context whose life cycle is defined by the Java EE specifications. For example, a session context and its beans exist during the lifetime of an HTTP session. Injected references to the beans are contextually aware. The references always apply to the bean that is associated with the context for the thread that is making the reference. The CDI container ensures that the objects are created and injected at the correct time as determined by the scope that is specified for these objects.

[Example 9-2](#) shows how to define the scope of a bean.

Example 9-2 Defining the Scope of a Bean

This example defines the scope of the `Accountant` bean class to be `@RequestScoped`.

The `Accountant` class in this example is qualified by the `@BeanCounter` qualifier. For more information, see [Section 9.6, "Using Qualifiers."](#)

```
package com.example.managers;

import javax.enterprise.context.RequestScoped;
```

```

@RequestScoped
@BeanCounter
public class Accountant implements Manager
{
    ...
}

```

9.5 Overriding the Scope of a Bean at the Point of Injection

Overriding the scope of a bean at the point of injection enables an application to request a new instance of the bean with the default scope `@Dependent`. The `@Dependent` scope specifies that the bean's life cycle is the life cycle of the object into which the bean is injected. The CDI container provides no other life cycle management for the instance. For more information about scopes, see [Section 9.4, "Defining the Scope of a Bean."](#)

Note: The effects of overriding the scope of a bean may be unpredictable and undesirable, particularly if the overridden scope is `@Request` or `@Session`.

To override the scope of a bean at the point of injection, inject the bean by using the `javax.enterprise.inject.New` annotation instead of the `@Inject` annotation. For more information about the `@Inject` annotation, see [Section 9.3, "Injecting a Bean."](#)

9.6 Using Qualifiers

Qualifiers enable you to provide more than one implementation of a particular bean type. When you use qualifiers, you select between implementations at development time. For more information, see *Using Qualifiers* in *The Java EE 7 Tutorial*.

Note: To select between alternative implementations at deployment time, use alternatives as explained in [Section 9.7, "Providing Alternative Implementations of a Bean Type."](#)

Using qualifiers involves the tasks that are explained in the following sections:

- [Section 9.6.1, "Defining Qualifiers for Implementations of a Bean Type"](#)
- [Section 9.6.2, "Applying Qualifiers to a Bean"](#)
- [Section 9.6.3, "Injecting a Qualified Bean"](#)

9.6.1 Defining Qualifiers for Implementations of a Bean Type

A qualifier is an application-defined annotation that enables you to identify an implementation of a bean type. Define a qualifier for each implementation of a bean type that you are providing.

Define qualifiers only if you are providing multiple implementations of a bean type and if you are not using alternatives. If no qualifiers are defined for a bean type, CDI applies the predefined qualifier `@Default` when a bean of the type is injected.

Note: CDI does not require a qualifier to be unique to a particular bean. You can define a qualifier to use for more than one bean type.

To define a qualifier:

1. Define a Java annotation type to represent the qualifier.
2. Annotate the declaration of the annotation type with the `javax.inject.Qualifier` annotation.
3. Specify that the qualifier is to be retained by the virtual machine at run time.
Use the `java.lang.annotation.Retention(RUNTIME)` meta-annotation for this purpose.
4. Specify that the qualifier may be applied to the program elements `METHOD`, `FIELD`, `PARAMETER`, and `TYPE`.
Use the `java.lang.annotation.Target({METHOD, FIELD, PARAMETER, TYPE})` meta-annotation for this purpose.

The following examples show how to define qualifiers `@BeanCounter` and `@PeopleManager` for different implementations of the same bean type.

Example 9-3 Defining the `@BeanCounter` Qualifier

This example defines the `@BeanCounter` qualifier.

```
package com.example.managers;

import static java.lang.annotation.ElementType.FIELD;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.PARAMETER;
import static java.lang.annotation.ElementType.TYPE;
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import java.lang.annotation.Retention;
import java.lang.annotation.Target;

import javax.inject.Qualifier;

@Qualifier
@Retention(RUNTIME)
@Target({METHOD, FIELD, PARAMETER, TYPE})
public @interface BeanCounter {}
```

Example 9-4 Defining the `@PeopleManager` Qualifier

This example defines the `@PeopleManager` qualifier.

```
package com.example.managers;

import static java.lang.annotation.ElementType.FIELD;
import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.PARAMETER;
import static java.lang.annotation.ElementType.TYPE;
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import java.lang.annotation.Retention;
import java.lang.annotation.Target;

import javax.inject.Qualifier;

@Qualifier
@Retention(RUNTIME)
@Target({METHOD, FIELD, PARAMETER, TYPE})
```

```
public @interface PeopleManager {}
```

9.6.2 Applying Qualifiers to a Bean

Applying qualifiers to a bean identifies the implementation of the bean type. You can apply any number of qualifiers or no qualifiers to a bean. If you do not apply any qualifiers to a bean, CDI implicitly applies the predefined qualifier `@Default` to the bean.

Note: CDI does not require a qualifier to be unique to a particular bean. You can apply the same qualifier to different types of beans in the set of beans that are available in the application.

To apply qualifiers to a bean, annotate the class declaration of the bean with each qualifier to apply. Any qualifier that you apply to a bean must be defined as explained in [Section 9.6.1, "Defining Qualifiers for Implementations of a Bean Type."](#)

The following examples show how to apply the qualifiers `@BeanCounter` and `@PeopleManager` to different implementations of the `Manager` bean type.

Example 9-5 Applying the `@BeanCounter` Qualifier to a Bean

This example applies the `@BeanCounter` qualifier to the `Accountant` class. The `Accountant` class is an implementation of the `Manager` bean type. The `@BeanCounter` qualifier is defined in [Example 9-3](#).

```
package com.example.managers;
...
@BeanCounter
public class Accountant implements Manager
{...}
```

Example 9-6 Applying the `@PeopleManager` Qualifier to a Bean

This example applies the `@PeopleManager` qualifier to the `Boss` class. The `Boss` class is an implementation of the `Manager` bean type. The `@PeopleManager` qualifier is defined in [Example 9-4](#).

```
package com.example.managers;
...
@PeopleManager
public class Boss implements Manager
{...}
```

9.6.3 Injecting a Qualified Bean

To inject a qualified bean, create an injection point and annotate the injection point with the bean's qualifiers. The qualifiers at the injection point define the overall requirements of the injection target. The CDI application must contain a CDI managed bean that matches the type of the injection point and the qualifiers with which the injection point is annotated. Otherwise, a deployment error occurs. For more information about how to create an injection point, see [Section 9.3, "Injecting a Bean."](#)

If you do not annotate the injection point, the predefined qualifier `@Default` is applied to the injection point by default.

CDI resolves the injection point by first matching the bean type and then matching implementations of that type with the qualifiers in the injection point.

Only one active bean class may match the bean type and qualifiers in the injection point. Otherwise, an error occurs.

A bean class is active in one of the following situations:

- The bean class is an alternative that is enabled.
- The bean class is not an alternative and no alternatives for its bean type are enabled.

For information about alternatives, see [Section 9.7, "Providing Alternative Implementations of a Bean Type."](#)

[Example 9–7](#) shows how to inject a qualified bean.

Example 9–7 Injecting a Qualified Bean

This example injects the `@BeanCounter` implementation of the `Manager` bean type. The `Manager` bean type is implemented by the following classes:

- `Accountant`, which is shown in [Example 9–5](#)
- `Boss`, which is shown in [Example 9–6](#)

In this example, the `Accountant` class is injected because the bean type and qualifier of this class match the bean type and qualifier in the injection point.

```
package com.example.managers;
...
import javax.inject.Inject;
...
public class PennyPincher {
    @Inject @BeanCounter Manager accountant;
    ...
}
```

9.7 Providing Alternative Implementations of a Bean Type

The environments for the development, testing, and production deployment of an enterprise application may be very different. Differences in configuration, resource availability, and performance requirements may cause bean classes that are appropriate to one environment to be unsuitable in another environment.

Different deployment scenarios may also require different business logic in the same application. For example, country-specific sales tax laws may require country-specific sales tax business logic in an order-processing application.

By providing alternative implementations of a bean type, you can modify an application at deployment time to meet such differing requirements. CDI enables you to select from any number of alternative bean type implementations for injection instead of a corresponding primary implementation. For more information, see [Using Alternatives in CDI Applications](#) in *The Java EE 7 Tutorial*.

Note: To select between alternative implementations at development time, use qualifiers as explained in [Section 9.6, "Using Qualifiers."](#)

Providing alternative implementations of a bean type involves the tasks that are explained in the following sections:

- [Section 9.7.1, "Defining an Alternative Implementation of a Bean Type"](#)

- [Section 9.7.2, "Selecting an Alternative Implementation of a Bean Type for an Application"](#)

9.7.1 Defining an Alternative Implementation of a Bean Type

To define an alternative implementation of a bean type:

1. Write a bean class of the same bean type as primary implementation of the bean type.

To ensure that any alternative can be injected into an application, you must ensure that all alternatives and the primary implementation are all of the same bean type. For information about how to inject a bean, see [Section 9.3, "Injecting a Bean."](#)

2. Annotate the class declaration of the implementation with the `javax.enterprise.inject.Alternative` annotation.

Note: To ensure that the primary implementation is selected by default, do not annotate the class declaration of the primary implementation with `@Alternative`.

The following examples show the declaration of the primary implementation and an alternative implementation of a bean type. The alternative implementation is a mock implementation that is intended for use in testing.

Example 9–8 Declaring a Primary Implementation of a Bean Type

This example declares the primary implementation `OrderImpl` of the bean type `Order`.

```
package com.example.orderprocessor;
...
public class OrderImpl implements Order {
    ...
}
```

Example 9–9 Declaring an Alternative Implementation of a Bean Type

This example declares the alternative implementation `MockOrderImpl` of the bean type `Order`. The declaration of the primary implementation of this bean type is shown in [Example 9–8](#).

```
package com.example.orderprocessor;
...
import javax.enterprise.inject.Alternative;

@Alternative
public class MockOrderImpl implements Order {
    ...
}
```

9.7.2 Selecting an Alternative Implementation of a Bean Type for an Application

By default, CDI selects the primary implementation of a bean type for injection into an application. If you require an alternative implementation to be injected, you must select the alternative explicitly.

To select an alternative implementation for an application:

1. Add a `class` element for the alternative to the `alternatives` element in the `beans.xml` file.
2. In the `class` element, provide the fully qualified class name of the alternative.

For more information about the `beans.xml` file, see [Section 9.19, "Configuring a CDI Application."](#)

[Example 9–16](#) shows a `class` element in the `beans.xml` file for selecting an alternative implementation of a bean type.

Example 9–10 Selecting an Alternative Implementation of a Bean Type

This example selects the alternative implementation `com.example.orderprocessor.MockOrderImpl`.

```
...
<alternatives>
  <class>com.example.orderprocessor.MockOrderImpl</class>
</alternatives>
...
```

9.8 Applying a Scope and Qualifiers to a Session Bean

CDI enables you to apply a scope and qualifiers to a session bean. A session bean is an EJB component that meets either of the following requirements:

- The class that implements the bean is annotated with one of the following annotations:
 - `javax.ejb.Singleton`, which denotes a singleton session bean
 - `javax.ejb.Stateful`, which denotes a stateful session bean
 - `javax.ejb.Stateless`, which denotes a stateless session bean
- The bean is listed in the `ejb-jar.xml` deployment-descriptor file.

For more information about session beans, see the following documents:

- *Developing Enterprise JavaBeans for Oracle WebLogic Server*
- *Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server*

9.8.1 Applying a Scope to a Session Bean

The scopes that CDI allows you to apply to a session bean depend on the type of the session bean as shown in [Table 9–1](#).

Table 9–1 Allowed CDI Scopes for Session Beans

Session Bean Type	Allowed Scopes
Singleton	Either of the following scopes: <ul style="list-style-type: none"> ■ Dependent ■ Application
Stateful	Any
Stateless	Dependent

For more information about scopes in CDI, see [Section 9.4, "Defining the Scope of a Bean."](#)

When CDI injects a reference to a stateful session bean, CDI creates the bean, injects the bean's fields, and manages the stateful session bean according to its scope. When the context is destroyed, CDI calls the stateful session bean's remove method to remove the bean.

9.8.2 Applying Qualifiers to a Session Bean

CDI allows you to apply any qualifier to a session bean. CDI does not restrict the type of qualifier that you can apply to a session bean. For more information about qualifiers in CDI, see [Section 9.6, "Using Qualifiers."](#)

9.9 Using Producer Methods, Disposer Methods, and Producer Fields

A producer method is a method that generates an object that can then be injected.

A disposer method enables an application to perform customized cleanup of an object that a producer method returns.

A producer field is a field of a bean that generates an object. A producer field is a simpler alternative to a producer method.

For more information, see [Using Producer Methods, Producer Fields, and Disposer Methods in CDI Applications in *The Java EE 7 Tutorial*](#).

9.9.1 Defining a Producer Method

A producer method enables an application to customize how CDI managed beans are created. This customization involves overriding the process that CDI normally uses to resolve beans. A producer method enables you to inject an object that is not an instance of a CDI bean class.

A producer method must be a method of a CDI bean class or session bean class. However, a producer method may return objects that are not instances of CDI bean classes. In this situation, the producer method must return an object that matches a bean type.

A producer method can have any number of parameters. If necessary, you can apply qualifiers to these parameters. All parameters of a producer method are injection points. Therefore, the parameters of a producer method do not require the `@Inject` annotation.

To define a producer method, annotate the declaration of the method with the `javax.enterprise.inject.Produces` annotation.

If the producer method sometimes returns null, set the scope of the method to dependent.

Note: Calling a producer method directly in application code does not invoke CDI.

For an example of the definition of a producer method, see [Example 9-11](#).

9.9.2 Defining a Disposer Method

If you require customized cleanup of an object that a producer method returns, define a disposer method in the class that declares the producer method.

To define a disposer method, annotate the disposed parameter in the declaration of the method with the `javax.enterprise.inject.Disposes` annotation. The type of the disposed parameter must be the same as the return type of the producer method.

A disposer method matches a producer method when the disposed object's injection point matches both the type and qualifiers of the producer method. You can define one disposer method to match to several producer methods in the class.

[Example 9–11](#) shows how to use the `@Produces` annotation to define a producer method and the `@Disposes` annotation to define a disposer method.

Example 9–11 Defining a Producer Method and Disposer Method

This example defines the producer method `connect` and the disposer method `close`.

The producer method `connect` returns an object of type `Connection`. In the disposer method `close`, the parameter `connection` is the disposed parameter. This parameter is of type `Connection` to match the return type of the producer method.

At run time, the CDI framework creates an instance of `SomeClass` and then calls the producer method. Therefore, the CDI framework is responsible for injecting the parameters that are passed to the producer method.

The scope of the producer method is `@RequestScoped`. When the request context is destroyed, if the `Connection` object is in the request context, CDI calls the disposer method for this object. In the call to the disposer method, CDI passes the `Connection` object as a parameter.

```
import javax.enterprise.inject.Produces;
import javax.enterprise.inject.Disposes;

import javax.enterprise.context.RequestScoped;

public class SomeClass {
    @Produces @RequestScoped
    public Connection connect(User user) {
        return createConnection(user.getId(),
            user.getPassword());
    }

    private Connection createConnection(
        String id, String password) {...}

    public void close(@Disposes Connection connection) {
        connection.close();
    }
}
```

9.9.3 Defining a Producer Field

A producer field is a simpler alternative to a producer method. A producer field must be a field of a managed bean class or session bean class. A producer field may be either static or nonstatic, subject to the following constraints:

- In a session bean class, the producer field must be a static field.
- In a managed bean class, the producer field can be either static or nonstatic.

To define a producer field, annotate the declaration of the field with the `javax.enterprise.inject.Produces` annotation.

If the producer field may contain a null when accessed, set the scope of the field to dependent.

Note: Using a producer field directly in application code does not invoke CDI.

Producer fields do not have disposers.

9.10 Initializing and Preparing for the Destruction of a Managed Bean

CDI managed bean classes and their superclasses support the annotations for initializing and preparing for the destruction of a managed bean. These annotations are defined in JSR 250: Common Annotations for the Java Platform. For more information, see [Chapter 8, "Using Java EE Annotations and Dependency Injection"](#).

9.10.1 Initializing a Managed Bean

Initializing a managed bean specifies the life cycle callback method that the CDI framework should call after dependency injection but before the class is put into service.

To initialize a managed bean:

1. In the managed bean class or any of its superclasses, define a method that performs the initialization that you require.
2. Annotate the declaration of the method with the `javax.annotation.PostConstruct` annotation.

When the managed bean is injected into a component, CDI calls the method after all injection has occurred and after all initializers have been called.

Note: As mandated by JSR 250, if the annotated method is declared in a superclass, the method is called unless a subclass of the declaring class overrides the method.

9.10.2 Preparing for the Destruction of a Managed Bean

Preparing for the destruction of a managed bean specifies the life cycle callback method that signals that an application component is about to be destroyed by the container.

To prepare for the destruction of a managed bean:

1. In the managed bean class or any of its superclasses, define a method that prepares for the destruction of the managed bean.

In this method, perform any cleanup that is required before the bean is destroyed, such as releasing resources that the bean has been holding.

2. Annotate the declaration of the method with the `javax.annotation.PreDestroy` annotation.

CDI calls the method before starting the logic for destroying the bean.

Note: As mandated by JSR 250, if the annotated method is declared in a superclass, the method is called unless a subclass of the declaring class overrides the method.

9.11 Intercepting Method Invocations and Life Cycle Events of Bean Classes

Intercepting a method invocation or a life cycle event of a bean class interposes an interceptor class in the invocation or event. When an interceptor class is interposed, additional actions that are defined in the interceptor class are performed. An interceptor class simplifies the maintenance of code for tasks that are frequently performed and are separate from the business logic of the application. Examples of such tasks are logging and auditing.

Note: The programming model for interceptor classes is optimized for operations that are separate from the business logic of the application. To intercept methods that perform operations with business semantics, use a decorator class as explained in [Section 9.12, "Decorating a Managed Bean Class."](#)

The interceptors that were introduced in the Java EE 5 specification are specific to EJB components. For more information about Java EE 5 interceptors, see "Specifying Interceptors for Business Methods or Life Cycle Callback Events" in *Developing Enterprise JavaBeans for Oracle WebLogic Server*.

CDI enables you to use interceptors with the following types of Java EE managed objects:

- CDI managed beans
- EJB session beans
- EJB message-driven beans

Note: You **cannot** use interceptors with EJB entity beans because CDI does not support EJB entity beans.

For more information, see Using Interceptors in *The Java EE 7 Tutorial*.

Intercepting method invocations and life cycle events of bean classes involves the tasks that are explained in the following sections:

- [Section 9.11.1, "Defining an Interceptor Binding Type"](#)
- [Section 9.11.2, "Defining an Interceptor Class"](#)
- [Section 9.11.3, "Identifying Methods for Interception"](#)
- [Section 9.11.4, "Enabling an Interceptor"](#)

9.11.1 Defining an Interceptor Binding Type

An interceptor binding type is an application-defined annotation that associates an interceptor class with an intercepted bean. Define an interceptor binding type for each type of interceptor that you require.

Note: CDI does not require an interceptor binding type to be unique to a particular interceptor class. You can define an interceptor binding type to use for more than one interceptor class.

To define an interceptor binding type:

1. Define a Java annotation type to represent the interceptor binding type.
2. Annotate the declaration of the annotation type with the `javax.interceptor.InterceptorBinding` annotation.
3. Specify that the interceptor binding type is to be retained by the virtual machine at run time.

Use the `java.lang.annotation.Retention(RUNTIME)` meta-annotation for this purpose.

4. Specify that the interceptor binding type may be applied to the program elements `METHOD` and `TYPE`.

Use the `java.lang.annotation.Target({METHOD, TYPE})` meta-annotation for this purpose.

Example 9–12 Defining An Interceptor Binding Type

This example defines the `@Transactional` interceptor binding type.

```
package com.example.billpayment.interceptor;

import static java.lang.annotation.ElementType.METHOD;
import static java.lang.annotation.ElementType.TYPE;
import static java.lang.annotation.RetentionPolicy.RUNTIME;

import java.lang.annotation.Retention;
import java.lang.annotation.Target;

import javax.interceptor.InterceptorBinding;

@InterceptorBinding
@Target({METHOD, TYPE})
@Retention(RUNTIME)
public @interface Transactional {}
```

9.11.2 Defining an Interceptor Class

An interceptor class is used to interpose in method invocations or life cycle events that occur in an associated target bean class. In an interceptor class, provide the code for tasks that are frequently performed and are separate from the business logic of the application, such as logging and auditing.

To define an interceptor class:

1. Define a Java class to represent the interceptor.
2. Annotate the declaration of the class with the following annotations:
 - `javax.interceptor.Interceptor`
 - The interceptor binding types that are defined for the class

You can apply any number of interceptor binding types to an interceptor class.

Note: CDI does not require an interceptor binding type to be unique to a particular interceptor class. You can apply the same interceptor binding type to multiple interceptor classes.

3. Implement the interceptor methods in the class.

CDI does not require the signature of an interceptor method to match the signature of the intercepted method.

4. Identify the interceptor methods in the class.

An interceptor method is the method that is invoked when a method invocation or a life cycle event of a bean class is intercepted.

To identify an interceptor method, annotate the declaration of the method with the appropriate annotation for the type of the interceptor method.

Interceptor Method Type	Annotation
Method invocation	<code>javax.interceptor.AroundInvoke</code>
EJB timeout	<code>javax.interceptor.AroundTimeout</code>
Initialization of a managed bean or EJB component	<code>javax.annotation.PostConstruct</code>
Destruction of a managed bean or EJB component	<code>javax.annotation.PreDestroy</code>
Activation of a stateful session bean	<code>javax.ejb.PostActivate</code>
Passivation of a stateful session bean	<code>javax.ejb.PrePassivate</code>

Note: An interceptor class can have multiple interceptor methods. However, an interceptor class can have no more than one interceptor method of a given type.

[Example 9–13](#) shows how to define an interceptor class.

Example 9–13 Defining an Interceptor Class

This example defines the interceptor class for which the `@Transactional` interceptor binding type is defined. The `manageTransaction` method of this class is an interceptor method. The `@Transactional` interceptor binding is defined in [Example 9–12](#).

```
package com.example.billpayment.interceptor;

import javax.annotation.Resource;
import javax.interceptor.*;
...
@Transactional @Interceptor
public class TransactionInterceptor {
    @Resource UserTransaction transaction;
    @AroundInvoke
    public Object manageTransaction(InvocationContext ctx)
        throws Exception {
        ...
    }
}
```

9.11.3 Identifying Methods for Interception

Identifying methods for interception associates the methods with the interceptor that is invoked when the methods are invoked. CDI enables you to identify all methods of a bean class or only individual methods of a bean class for interception.

- To identify all methods of a bean class for interception, annotate the declaration of the bean class with the appropriate interceptor binding type.
- To identify an individual method of a bean class for interception, annotate the declaration of the method with the appropriate interceptor binding type.

CDI does not require the signature of an intercepted method to match the signature of the interceptor method. To determine the arguments and return type of an intercepted method, an interceptor must query an interceptor context. Therefore, you can intercept any method or life cycle event in a bean class without any knowledge at compilation time of the interfaces of bean class.

Note: An implementation of a Java EE 5 interceptor must be declared in the annotation on the method that is to be intercepted. A CDI interceptor uses an interceptor binding to identify an interceptor method and to relate an intercepted method to its interceptor method. Both the intercepted method and the interceptor method must be annotated with the binding. In this way, the intercepted method and the interceptor are related to each other only through the interceptor binding.

Example 9–14 Identifying All Methods of a Bean Class for Interception

This example identifies all methods of the `ShoppingCart` class for interception by the `@Transactional` interceptor.

```
package com.example.billpayment.interceptor;

@Transactional
public class ShoppingCart {
    ...
}
```

Example 9–15 Identifying an Individual Method of a Class for Interception

This example identifies only the `checkout` method of the `ShoppingCart` class for interception by the `@Transactional` interceptor.

```
package com.example.billpayment.interceptor;

public class ShoppingCart {
    ...
    @Transactional public void checkout() {
        ...
    }
}
```

9.11.4 Enabling an Interceptor

By default, an interceptor is disabled. If you require an interceptor to be interposed in method invocations and events, you must enable the interceptor explicitly.

To enable an interceptor:

1. Add a `class` element for the interceptor to the `interceptors` element in the `beans.xml` file.
2. In the `class` element, provide the fully qualified class name of the interceptor.

Ensure that the order of the `class` elements in the `beans.xml` file matches the order in which the interceptors are to be invoked.

CDI interceptors are invoked in the order in which they are declared in the `beans.xml` file. Interceptors that are defined in the `ejb-jar.xml` file or by the `javax.interceptor.Interceptors` annotation are called before the CDI interceptors. Interceptors are called before CDI decorators.

Note: Java EE 5 interceptors are invoked in the order in which they are annotated on an intercepted method.

For more information about the `beans.xml` file, see [Section 9.19, "Configuring a CDI Application."](#)

[Example 9–16](#) shows a `class` element in the `beans.xml` file for enabling an interceptor class.

Example 9–16 Enabling an Interceptor Class

This example enables the interceptor class `com.example.billpayment.interceptor.TransactionInterceptor`. The interceptor class is defined in [Example 9–13](#).

```
...
<interceptors>
  <class>com.example.billpayment.interceptor.TransactionInterceptor</class>
</interceptors>
...
```

9.12 Decorating a Managed Bean Class

Decorating a managed bean class enables you to intercept invocations of methods in the decorated class that perform operations with business semantics. You can decorate any managed bean class.

Note: The programming model for decorator classes is optimized for operations that perform the business logic of the application. To intercept methods that are separate from the business logic of an application, use an interceptor class as explained in [Section 9.11, "Intercepting Method Invocations and Life Cycle Events of Bean Classes."](#)

For more information, see Using Decorators in *The Java EE 7 Tutorial*.

Decorating a managed bean class involves the tasks that are explained in the following sections:

- [Section 9.12.1, "Defining a Decorator Class"](#)
- [Section 9.12.2, "Enabling a Decorator Class"](#)

9.12.1 Defining a Decorator Class

A decorator class intercepts invocations of methods in the decorated class that perform operations with business semantics. A decorator class and an interceptor class are similar because both classes provide an around-method interception. However, a method in a decorator class has the same signature as the intercepted method in the decorated bean class.

To define a decorator class:

1. Write a Java class that implements the same interface as the bean class that you are decorating.

If you want to intercept only some methods of the decorated class, declare the decorator class as an abstract class. If you declare the class as abstract, you are not required to implement all the methods of the bean class that you are decorating.

2. Annotate the class declaration of the decorator class with the `javax.decorator.Decorator` annotation.

3. Implement the methods of the decorated bean class that you want to intercept.

If the decorator class is a concrete class, you must implement all the methods of the bean class that you are decorating.

You must ensure that the intercepting method in a decorator class has the same signature as the intercepted method in the decorated bean class.

4. Add a delegate injection point to the decorator class.

A decorator class must contain exactly one delegate injection point. A delegate injection point injects a delegate object, which is an instance of the decorated class, into the decorator object.

You can customize how any method in the decorator object handles the implementation of the decorated method. CDI allows but does not require the decorator object to invoke the corresponding delegate object. Therefore, you are free to choose whether the decorator object invokes the corresponding delegate object.

- a. In the decorator class, inject an instance of the bean class that you are decorating.
- b. Annotate the injection point with the `javax.decorator.Delegate` annotation.
- c. Apply qualifiers that you require to the injection point, if any.

If you apply qualifiers to the injection point, the decorator applies only to beans whose bean class matches the qualifiers of the injection point.

Note: No special declaration, such as an annotation, is required to define a decorated bean class. An enabled decorator class applies to any bean class or session bean that matches the bean type and qualifiers of the delegate injection point.

[Example 9–17](#) shows the definition of a decorator class.

Example 9–17 *Defining a Decorator Class*

This example defines the decorator class `DataAccessAuthDecorator`. This class decorates any bean of type `DataAccess`.

Because only some methods of the decorated class are to be intercepted, the class is declared as an abstract class. This class injects a delegate instance delegate of the decorated implementation of the `DataAccess` bean type.

```
import javax.decorator.*;
import javax.inject.Inject;
import java.lang.Override;
...
@Decorator
public abstract class DataAccessAuthDecorator
    implements DataAccess {

    @Inject @Delegate DataAccess delegate;

    @Override
    public void delete(Object object) {
        authorize(SecureAction.DELETE, object);
        delegate.delete(object);
    }

    private void authorize(SecureAction action, Object object) {
        ...
    }
}
```

9.12.2 Enabling a Decorator Class

By default, a decorator class is disabled. If you require a decorator class to be invoked in a CDI application, you must enable the decorator class explicitly.

To enable an decorator class:

1. Add a `class` element for the decorator class to the `decorators` element in the `beans.xml` file.
2. In the `class` element, provide the fully qualified class name of the decorator class.

Ensure that the order of the `class` elements in the `beans.xml` file matches the order in which the decorator classes are to be invoked.

Note: Any interceptor classes that are defined for an application are invoked before the application's decorator classes.

For more information about the `beans.xml` file, see [Section 9.19, "Configuring a CDI Application."](#)

[Example 9–18](#) shows a `class` element in the `beans.xml` file for enabling a decorator class.

Example 9–18 Enabling a Decorator Class

This example enables the decorator class

```
com.example.billpayment.decorator.DataAccessAuthDecorator.
```

```
...
<decorators>
    <class>com.example.billpayment.decorator.DataAccessAuthDecorator</class>
</decorators>
...
```

9.13 Assigning an EL Name to a CDI Bean Class

EL enables components in the presentation layer to communicate with managed beans that implement application logic. Components in the presentation layer are typically JavaServer Faces (JSF) pages and JavaServer Pages (JSP) pages. For more information, see "JSP Expression Language" in *Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server*.

In the scripting languages in JSP pages and JSF pages, the syntax of an injected variable is identical to the syntax of a built-in variable of these languages. Any CDI bean that is injected into a JSP page or JSF page must be accessible through an EL name. For more information, see Giving Beans EL Names in *The Java EE 7 Tutorial*.

To assign an EL name to a CDI bean class, annotate the class declaration of the bean class with the `javax.inject.Named` annotation.

If you do not specify a name, the EL name is the unqualified class name with the first character in lower case. For example, if the unqualified class name is `ShoppingCart`, the EL name is `shoppingCart`.

To specify a name, set the `value` element of the `@Named` annotation to the name that you require.

Note: To assign an EL name to a CDI bean class, you must annotate the bean class declaration with the `@Named` annotation. If the class is not annotated with `@Named`, the CDI bean class does not have an EL name.

[Example 9–19](#) shows how to use the `@Named` annotation to assign an EL name to a CDI bean class.

Example 9–19 Assigning an EL Name to a Bean Class

This example assigns the EL name `cart` to the `ShoppingCart` class.

```
import javax.enterprise.context.SessionScoped;

@SessionScoped
@Named("cart")
public class ShoppingCart {
    public String getTotal() {
        ...
    }

    ...
}
```

Any bean that a JSP page or JSF page accesses must conform to the JavaBeans standard. To access a CDI managed bean from a JSP page or JSF page through the bean's EL name, use a syntax that is similar to the syntax for JavaBeans components.

[Example 9–20](#) shows how an instance of the `ShoppingCart` class is accessed in a JSF page through the EL name that is assigned to the class.

Example 9–20 Accessing a Bean Through its EL Name

This example accesses an instance of the `ShoppingCart` class to display the value of its `total` property in a JSF page.

This property is returned by the `getTotal` getter method of the `ShoppingCart` class as shown in [Example 9–19](#).

```
...
<h:outputText value="#{cart.total}"/>
...
```

9.14 Defining and Applying Stereotypes

In a large application in which several beans perform similar functions, you may require the same set of annotations to be applied to several bean classes. Defining a stereotype requires you to define the set of annotations only once. You can then use the stereotype to guarantee that the same set of annotations is applied to all bean classes that require the annotations. For more information, see *Using Stereotypes in The Java EE 7 Tutorial*.

Defining and applying stereotypes involves the tasks that are explained in the following sections:

- [Section 9.14.1, "Defining a Stereotype"](#)
- [Section 9.14.2, "Applying Stereotypes to a Bean"](#)

9.14.1 Defining a Stereotype

A stereotype is an application-defined annotation type that incorporates other annotation types.

To define a stereotype:

1. Define a Java annotation type to represent the stereotype.
2. Annotate the declaration of the annotation type with the following annotations:
 - `javax.enterprise.inject.Stereotype`
 - The other annotation types that you want the stereotype to incorporate

You can specify the following annotation types in a stereotype:

 - A default scope—see [Section 9.4, "Defining the Scope of a Bean"](#)
 - `@Alternative`—see [Section 9.7, "Providing Alternative Implementations of a Bean Type"](#)
 - One or more interceptor bindings—see [Section 9.11, "Intercepting Method Invocations and Life Cycle Events of Bean Classes"](#)
 - `@Named`—see [Section 9.13, "Assigning an EL Name to a CDI Bean Class"](#)
3. Specify that the stereotype is to be retained by the virtual machine at run time.

Use the `java.lang.annotation.Retention(RUNTIME)` meta-annotation for this purpose.
4. Specify that the stereotype may be applied to the program element `TYPE`.

Use the `java.lang.annotation.Target(TYPE)` meta-annotation for this purpose.

The following example shows the definition of a stereotype.

Example 9–21 Defining a Stereotype

This example defines the stereotype `@Action`, which specifies the following for each bean that the stereotype annotates:

- The default scope is request scope unless the scope is overridden with a scope annotation.
- The default EL name is assigned to the bean unless the name is overridden with the `@Named` annotation.
- The interceptor bindings `@Secure` and `@Transactional` are applied to the bean. The definition of these interceptor bindings is beyond the scope of this example.

```
import javax.enterprise.inject.Stereotype;
import javax.inject.Named;
import javax.enterprise.context.RequestScoped;
import static java.lang.annotation.ElementType.TYPE;
import static java.lang.annotation.RetentionPolicy.RUNTIME;
import java.lang.annotation.Retention;
import java.lang.annotation.Target;

@RequestScoped
@Secure
@Transactional
@Named
@Stereotype
@Target(TYPE)
@Retention(RUNTIME)
public @interface Action {}
```

9.14.2 Applying Stereotypes to a Bean

To apply stereotypes to a bean, annotate the class declaration of the bean with each stereotype to apply. You can apply any number of stereotypes to a bean. Any stereotype that you apply to a bean must be defined as explained in [Section 9.14.1, "Defining a Stereotype."](#)

[Example 9–22](#) shows how to apply stereotypes to a bean.

Example 9–22 Applying Stereotypes to a Bean

This example applies the stereotypes `@Action` and `@Mock` to the bean class `MockLoginAction`. The definition of the `@Action` stereotype is shown in [Example 9–21](#). The definition of the `@Mock` stereotype is beyond the scope of this example.

```
@Action
@Mock
public class MockLoginAction extends LoginAction {
    ...
}
```

9.15 Using Events for Communications Between Beans

At run time, your application may perform operations that generate information or cause state changes that must be communicated between beans. For example, an application may require stateful beans in one architectural tier of the application to synchronize their internal state with state changes that occur in a different tier.

Events enable beans to communicate this information without any compilation-time dependency. One bean can define an event, another bean can send the event, and yet another bean can handle the event. The beans can be in separate packages and even in separate tiers of the application. For more information, see *Using Events in The Java EE 7 Tutorial*.

Using events for communications between beans involves the tasks that are explained in the following sections:

- [Section 9.15.1, "Defining an Event Type"](#)
- [Section 9.15.2, "Sending an Event"](#)
- [Section 9.15.3, "Handling an Event"](#)

9.15.1 Defining an Event Type

An event type is a Java class that represents the information that you want to communicate between beans. For example, an event type may represent the state information that a stateful bean must synchronize with state changes in a different tier of an application.

Define an event type for each set of changes that you want to communicate between beans.

To define an event type:

1. Define a Java class to represent the event type.
Ensure that the class meets these requirements:
 - The class is declared as a concrete Java class.
 - The class has no type variables.
The event types of the event include all superclasses and interfaces of the run time class of the event object. An event type must not contain a type variable. Any Java type can be an observed event type.
2. If necessary, define any qualifiers to further distinguish events of this type. For more information, see [Section 9.6.1, "Defining Qualifiers for Implementations of a Bean Type."](#)
3. Provide code in the class to populate the event payload of event objects that are instantiated from the class.

The event payload is the information that you want the event to contain. You can use a JavaBeans property with getter and setter methods to represent an item of information in the event payload.

9.15.2 Sending an Event

To communicate a change that occurs in response to an operation, your application must send an event of the correct type when performing the operation. CDI provides a predefined event dispatcher object that enables application code to send an event and select the associated qualifiers at run time.

To send an event:

1. Obtain an instance of the event type to send.
2. Call methods of the event instance to populate the event payload of the event object that you are sending.
3. Inject an instance of the parameterized `javax.enterprise.event.Event` interface.
If you are sending a qualified event, annotate the injection point with the event qualifier.
4. Call the `fire` method of the injected `Event` instance.

In the call to the `fire` method, pass as a parameter the event instance that you are sending.

[Example 9–23](#) shows how to send an event.

Example 9–23 Sending an Event

This example injects an instance of the event of type `User` with the qualifier `@LoggedIn`. The `fire` method sends only `User` events to which the `@LoggedIn` qualifier is applied.

```
import javax.enterprise.event.Event;
import javax.enterprise.context.SessionScoped;
import javax.inject.Inject;
import java.io.Serializable;

@SessionScoped
public class Login implements Serializable {

    @Inject @LoggedIn Event<User> userLoggedInEvent;
    private User user;

    public void login(Credentials credentials) {

        //... use credentials to find user

        if (user != null) {
            userLoggedInEvent.fire(user);
        }
        ...
    }
}
```

9.15.3 Handling an Event

Any CDI managed bean class can handle events.

To handle an event:

1. In your bean class, define a method to handle the event.

Note: If qualifiers are applied to an event type, define one method for each qualified type.

2. In the signature of the method, define a parameter for passing the event to the method.

Ensure that the type of the parameter is the same as the Java type of the event.

3. Annotate the parameter in the method signature with the `javax.enterprise.event.Observes` annotation.

If necessary, set elements of the `@Observes` annotation to specify whether the method is conditional or transactional. For more information, see *Using Observer Methods to Handle Events in The Java EE 7 Tutorial*.

4. If the event type is qualified, apply the qualifier to the annotated parameter.
5. In the method body, provide code for handling the event payload of the event object.

[Example 9–24](#) shows how to declare an observer method for receiving qualified events of a particular type. [Example 9–25](#) shows how to declare an observer method for receiving all events of a particular type.

Example 9–24 Handling a Qualified Event of a Particular Type

This example declares the `afterLogin` method in which the parameter `user` is annotated with the `@Observes` annotation and the `@LoggedIn` qualifier. This method is called when an event of type `User` with the qualifier `@LoggedIn` is sent.

```
import javax.enterprise.event.Observes;

    public void afterLogin(@Observes @LoggedIn User user) {
        ...
    }
```

Example 9–25 Handling Any Event of a Particular Type

This example declares the `afterLogin` method in which the parameter `user` is annotated with the `@Observes` annotation. This method is called when any event of type `User` is sent.

```
import javax.enterprise.event.Observes;

    public void afterLogin(@Observes User user) {
        ...
    }
```

9.16 Injecting a Predefined Bean

CDI provides predefined beans that implement the following interfaces:

javax.transaction.UserTransaction

Java Transaction API (JTA) user transaction.

java.security.Principal

The abstract notion of a principal, which represents any entity, such as an individual, a corporation, and a login ID.

The principal represents the identity of the current caller. Whenever the injected principal is accessed, it always represents the identity of the current caller.

For example, a principal is injected into a field at initialization. Later, a method that uses the injected principal is called on the object into which the principal was injected. In this situation, the injected principal represents the identity of the current caller when the method is run.

javax.validation.Validator

Validator for bean instances.

The bean that implements this interface enables a `Validator` object for the default bean validation `ValidatorFactory` object to be injected.

javax.validation.ValidatorFactory

Factory class for returning initialized `Validator` instances.

The bean that implements this interface enables the default bean validation `ValidatorFactory` object to be injected.

To inject a predefined bean, create an injection point by using the `javax.annotation.Resource` annotation to obtain an instance of the bean. For the bean type, specify the class name of the interface that the bean implements.

Predefined beans are injected with dependent scope and the predefined default qualifier `@Default`.

For more information about injecting resources, see Resource Injection in *The Java EE 7 Tutorial*.

[Example 9–26](#) shows how to use the `@Resource` annotation to inject a predefined bean.

Example 9–26 Injecting a Predefined Bean

This example injects a user transaction into the servlet class `TransactionServlet`. The user transaction is an instance of the predefined bean that implements the `javax.transaction.UserTransaction` interface.

```
import javax.annotation.Resource;
import javax.servlet.http.*;
...
public class TransactionServlet extends HttpServlet {
    @Resource UserTransaction transaction;
    ...
}
```

9.17 Injecting and Qualifying Resources

Java EE 5 resource injection relies on strings for configuration. Typically, these strings are JNDI names that are resolved when an object is created. CDI ensures type-safe injection of beans by selecting the bean class on the basis of the Java type that is specified in the injection point.

Even in a CDI bean class, Java EE 5 resource injection is required to access real resources such as data sources, Java Message Service (JMS) resources, and Web service references. Because CDI bean classes can use Java EE 5 resource injection, you can use producer fields to minimize the reliance on Java EE 5 resource injection. In this way, CDI simplifies how to encapsulate the configuration that is required to access the correct resource.

To minimize the reliance on Java EE 5 resource injection:

1. Use Java EE 5 resource injection in only one place in the application.
2. Use producer fields to translate the injected resource type into a CDI bean.

You can inject this CDI bean into the application in the same way as any other CDI bean.

For more information about producer fields, see [Section 9.9.3, "Defining a Producer Field."](#)

[Example 9–27](#) shows how to use Java EE 5 annotations to inject resources.

[Example 9–28](#) shows how to inject the same set of resources by combining Java EE 5 resource injection with CDI producer fields.

Example 9–27 Using Java EE 5 Annotations to Inject Resources

```
import javax.annotation.Resource;
import javax.persistence.PersistenceContext;
import javax.persistence.PersistenceUnit;
import javax.ejb.EJB;
```

```

import javax.xml.ws.WebServiceRef;
...
public class SomeClass {

    @WebServiceRef(lookup="java:app/service/PaymentService")
    PaymentService paymentService;

    @EJB(ejbLink=" ../payment.jar#PaymentService")
    PaymentService paymentService;

    @Resource(lookup="java:global/env/jdbc/CustomerDatasource")
    Datasource customerDatabase;

    @PersistenceContext(unitName="CustomerDatabase")
    EntityManager customerDatabasePersistenceContext;

    @PersistenceUnit(unitName="CustomerDatabase")
    EntityManagerFactory customerDatabasePersistenceUnit;

    ...
}

```

Example 9–28 Combining Java EE 5 Resource Injection With Producer Fields

The declaration of the `SomeClass` class is annotated with `@ApplicationScoped` to set the scope of this bean to application. The `@Dependent` scope is implicitly applied to the producer fields.

```

import javax.enterprise.context.ApplicationScoped;
import javax.enterprise.inject.Produces;
import javax.annotation.Resource;
import javax.persistence.PersistenceContext;
import javax.persistence.PersistenceUnit;
import javax.ejb.EJB;
import javax.xml.ws.WebServiceRef;
...
@ApplicationScoped
public class SomeClass {

    @Produces
    @WebServiceRef(lookup="java:app/service/PaymentService")
    PaymentService paymentService;

    @Produces
    @EJB(ejbLink=" ../their.jar#PaymentService")
    PaymentService paymentService;

    @Produces @CustomerDatabase
    @Resource(lookup="java:global/env/jdbc/CustomerDatasource")
    Datasource customerDatabase;

    @Produces @CustomerDatabase
    @PersistenceContext(unitName="CustomerDatabase")
    EntityManager customerDatabasePersistenceContext;

    @Produces @CustomerDatabase
    @PersistenceUnit(unitName="CustomerDatabase")
    EntityManagerFactory customerDatabasePersistenceUnit;

    ...
}

```

CDI enables you to use Java EE resources in CDI applications in a way that is consistent with CDI. To use Java EE resources in this way, inject the resources as CDI beans into other beans.

[Example 9–29](#) shows how to inject a Java EE resource as a CDI bean into another bean.

Example 9–29 *injecting a Java EE Resource as a CDI Bean Into Another Bean*

This example injects a persistence unit resource into a request-scoped bean.

```
import javax.enterprise.context.RequestScoped;
import javax.enterprise.inject.Inject;

@RequestScoped
public class SomeOtherClass {
    ...
    @Inject @CustomerDatabase
    private EntityManagerFactory emf;
    ...
}
```

Another class, for example `YetAnotherClass`, could inject a field of type `SomeOtherClass`. If an instance of `SomeOtherClass` does not already exist in the current request context, CDI performs the following sequence of operations:

1. Constructing the instance of `SomeOtherClass`
2. Injecting the reference to the entity manager factory by using the producer field from [Example 9–28](#)
3. Saving the new instance of `SomeOtherClass` in the current request context

In every case, CDI injects the reference to this instance of `SomeOtherClass` into the field in `YetAnotherClass`. When the request context is destroyed, the instance of `SomeOtherClass` and its reference to the entity manager factory are destroyed.

9.18 Using CDI With JCA Technology

WebLogic Server supports CDI in embedded resource adapters and global resource adapters. To enable a resource adapter for CDI, provide a `beans.xml` file in the `META-INF` directory of the packaged archive of the resource adapter. For more information about the `beans.xml` file, see [Section 9.19, "Configuring a CDI Application."](#)

All classes in the resource adapter are available for injection. All classes in the resource adapter can be CDI managed beans except for the following classes:

- **Resource adapter beans.** These beans are classes that are annotated with the `javax.resource.spi.Connector` annotation or are declared as corresponding elements in the resource adapter deployment descriptor `ra.xml`.
- **Managed connection factory beans.** These beans are classes that are annotated with the `javax.resource.spi.ConnectionDefinition` annotation or the `javax.resource.spi.ConnectionDefinitions` annotation, or are declared as corresponding elements in `ra.xml`.
- **Activation specification beans.** These beans are classes that are annotated with the `javax.resource.spi.Activation` annotation or are declared as corresponding elements in `ra.xml`.

- **Administered object beans.** These beans are classes that are annotated with the `javax.resource.spi.AdministeredObject` annotation or are declared as corresponding elements in `ra.xml`.

9.19 Configuring a CDI Application

Configuring a CDI application enables CDI services for the application. You must configure a CDI application to identify the application as a CDI application. No special declaration, such as an annotation, is required to define a CDI managed bean. And no module type is defined specifically for packaging CDI applications.

To configure a CDI application, provide a file that is named `beans.xml` in the packaged archive of the application. The `beans.xml` file must be an instance of the extensible markup language (XML) schema `beans_1_0.xsd`.

If your application does **not** use any alternatives, interceptors, or decorators, the `beans.xml` file can be empty. However, you must provide the `beans.xml` file even if the file is empty.

If your CDI application uses alternatives, interceptors, or decorators, you must enable these items by declaring them in the `beans.xml` file. For more information, see:

- [Section 9.7.2, "Selecting an Alternative Implementation of a Bean Type for an Application"](#)
- [Section 9.11.4, "Enabling an Interceptor"](#)
- [Section 9.12.2, "Enabling a Decorator Class"](#)

The required location of the `beans.xml` file depends on the type of the application:

- For a Web application, the `beans.xml` file must be in the `WEB-INF` directory.
- For an EJB module, resource archive (RAR) file, application client JAR file, or library JAR file, the `beans.xml` file must be in the `META-INF` directory.

You can provide CDI bean archives in the `lib` directory of an EJB module. You must provide a `beans.xml` file in the `META-INF` directory of each CDI bean archive the `lib` directory of an EJB module.

[Example 9–30](#) shows a `beans.xml` file for configuring a CDI application.

Example 9–30 *beans.xml* File for Configuring a CDI Application

This example configures a CDI application by enabling the following classes:

- The alternative implementation `com.example.orderprocessor.MockOrderImpl`
- The interceptor class `com.example.billpayment.interceptor.TransactionInterceptor`
- The decorator class `com.example.billpayment.decorator.DataAccessAuthDecorator`

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://java.sun.com/xml/ns/javaee"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
    http://java.sun.com/xml/ns/javaee
    http://java.sun.com/xml/ns/javaee/beans_1_1.xsd">
<alternatives>
  <class>com.example.orderprocessor.MockOrderImpl</class>
</alternatives>
<interceptors>
```

```

    <class>com.example.billpayment.interceptor.TransactionInterceptor</class>
</interceptors>
<decorators>
    <class>com.example.billpayment.decorator.DataAccessAuthDecorator</class>
</decorators>
</beans>

```

9.20 Supporting Third-Party Portable Extensions

CDI is intended to be a foundation for frameworks, extensions, and integration with other technologies. Therefore, CDI exposes SPIs that enable the development of portable extensions to CDI, such as:

- Integration with business process management engines
- Integration with third-party frameworks such as Spring, Seam, GWT or Wicket
- New technology that is based upon the CDI programming model

The SPIs that enable the development of portable extensions to CDI are provided in the `javax.enterprise.inject.spi` package.

Code in CDI extensions can handle events that are sent by the CDI framework.

For more information, see "Portable extensions" in JSR 346: Contexts and Dependency Injection for the Java EE platform.

9.21 Enabling and Disabling Implicit Bean Discovery

CDI 1.1 and Java EE 7 introduced the notion of implicit bean archives. An implicit bean archive is an archive (JAR file, WAR file, etc.) that does not contain a `beans.xml` file; it contains beans that can be managed by CDI. This can significantly increase the time taken to deploy an application. This increase in time is especially noticeable when applications built for releases prior to Java EE 7 are deployed on a Java EE 7 application server.

The implicit bean discovery is enabled by default. WebLogic Server provides the ability to enable or disable this feature using WLST commands.

The following examples demonstrate how to enable or disable implicit bean discovery using WLST commands in online mode and offline mode.

Example 9-31 Enabling or Disabling Implicit Bean Discovery using WLST in the Online Mode

In the following example, WLS must be running. The 'user' and 'password' must be your Administration user and password, and the 'url' must be the url of the machine on which the Administration server is running, for instance, `localhost:7001`. Also note that, 'mydomain' should match the domain name.

```

connect('user', 'password', 'url')
domainConfig()
edit()
cd('CdiContainer/mydomain')
startEdit()
set('ImplicitBeanDiscoveryEnabled',1) // 1 to enable 0 to disable
validate()
save()
activate(block="true")

```

Example 9-32 Enabling or Disabling Implicit Bean Discovery using WLST in the Offline Mode

In the following example, the 'domain' must be the path of your domain, for instance, /oracle/wls/mydomain. Also note that, 'mydomain' should match the domain name.

```
readDomain(domain)
create('mydomain','CdiContainer')
cd('CdiContainer/mydomain')
set('ImplicitBeanDiscoveryEnabled',1)
// 1 to enable 0 to disable
updateDomain()
closeDomain()
```

Java API for JSON Processing

WebLogic Server supports the Java API for JSON Processing 1.0 (JSR 353) specification by including the JSR-353 reference implementation for use with applications deployed on a WebLogic Server instance.

This chapter includes the following sections:

- [Section 10.1, "About JavaScript Object Notation \(JSON\)"](#)
- [Section 10.2, "Object Model API"](#)
- [Section 10.3, "Streaming API"](#)

To learn more about JSON concepts, see the "JSON Processing" chapter in the Java EE 7 Tutorial at <http://docs.oracle.com/javaee/7/tutorial/jsonp.htm#GLRBB>.

10.1 About JavaScript Object Notation (JSON)

JSON is a lightweight data-interchange format that is widely used as a common format to serialize and deserialize data in applications that communicate with each other over the Internet. These applications are often created using different programming languages and run in very different environments. JSON is suited to this scenario because it is an open standard, it is easy to read and write, and it is more compact than other representations. RESTful web services typically make extensive use of JSON as the format for the data inside requests and responses, with the JSON representations usually being more compact than the counterpart XML representations since JSON does not have closing tags.

The Java API for JSON Processing provides a convenient way to process (parse, generate, transform, and query) JSON text. For generating and parsing JSON data, there are two programming models, which are similar to those used for XML documents:

- The **object model** creates a tree that represents the JSON data in memory. The tree can then be navigated and analyzed. Although the JSON data created in memory is immutable and cannot be modified, the object model is the most flexible and allows for processing that requires access to the complete contents of the tree. However, it is often slower than the streaming model and requires more memory. The object model generates JSON output by navigating the entire tree at once.

For information about using the object model, see [Section 10.2, "Object Model API"](#).

- The **streaming model** uses an event-based parser that reads JSON data one element at a time. The parser generates events and stops for processing when an object or an array begins or ends, when it finds a key, or when it finds a value. Each element can be processed or discarded by the application code, and then the

parser proceeds to the next event. This approach is adequate for local processing, in which the processing of an element does not require information from the rest of the data. The streaming model generates JSON output to a given stream by making a function call with one element at a time.

For information about using the streaming model, see [Section 10.3, "Streaming API"](#).

10.2 Object Model API

The object model API is a high-level API that provides immutable object models for JSON object and array structures. These JSON structures are represented as object models using the Java types `JsonObject` and `JsonArray`. The interface `javax.json.JsonObject` provides a map view to access the unordered collection of zero or more name-value pairs from the model. Similarly, the `javax.json.JsonArray` interface provides a list view to access the ordered sequence of zero or more values from the model.

The object model API uses builder patterns to create these object models. The `javax.json.JsonObjectBuilder` and `javax.json.JsonArrayBuilder` interfaces provide methods to create models of type `JsonObject` and `JsonArray`, respectively.

These object models can also be created from an input source using the `javax.json.JsonReader` interface. Similarly, these object models can be written to an output source using the `javax.json.JsonWriter` interface.

The following sections show examples of using the object model API:

- [Creating an Object Model from JSON Data](#)
- [Creating an Object Model from Application Code](#)
- [Navigating an Object Model](#)
- [Writing an Object Model to a Stream](#)

10.2.1 Creating an Object Model from JSON Data

The following example shows how to create an object model from JSON data in a text file:

```
import java.io.FileReader;
import javax.json.Json;
import javax.json.JsonReader;
import javax.json.JsonStructure;
...
JsonReader reader = Json.createReader(new FileReader("jsondata.txt"));
JsonStructure jsonst = reader.read();
```

The object reference `jsonst` can be either of type `JsonObject` or of type `JsonArray`, depending on the contents of the file. `JsonObject` and `JsonArray` are subtypes of `JsonStructure`. This reference represents the top of the tree and can be used to navigate the tree or to write it to a stream as JSON data.

10.2.2 Creating an Object Model from Application Code

The following example shows how to create an object model from application code:

```
import javax.json.Json;
import javax.json.JsonObject;
...

```

```

JsonObject model = Json.createObjectBuilder()
    .add("firstName", "Duke")
    .add("lastName", "Java")
    .add("age", 18)
    .add("streetAddress", "100 Internet Dr")
    .add("city", "JavaTown")
    .add("state", "JA")
    .add("postalCode", "12345")
    .add("phoneNumbers", Json.createArrayBuilder()
        .add(Json.createObjectBuilder()
            .add("type", "mobile")
            .add("number", "111-111-1111"))
        .add(Json.createObjectBuilder()
            .add("type", "home")
            .add("number", "222-222-2222")))
    .build();

```

The object reference model represents the top of the tree, which is created by nesting invocations to the `add` methods and is built by invoking the `build` method. The `javax.json.JsonObjectBuilder` interface contains the following `add` methods:

```

JsonObjectBuilder add(String name, BigDecimal value)
JsonObjectBuilder add(String name, BigInteger value)
JsonObjectBuilder add(String name, boolean value)
JsonObjectBuilder add(String name, double value)
JsonObjectBuilder add(String name, int value)
JsonObjectBuilder add(String name, JsonArrayBuilder builder)
JsonObjectBuilder add(String name, JsonObjectBuilder builder)
JsonObjectBuilder add(String name, JsonValue value)
JsonObjectBuilder add(String name, long value)
JsonObjectBuilder add(String name, String value)
JsonObjectBuilder addNull(String name)

```

The `javax.json.JsonArrayBuilder` interface contains similar `add` methods that do not have a name (key) parameter. You can nest arrays and objects by passing a new `JsonArrayBuilder` object or a new `JsonObjectBuilder` object to the corresponding `add` method, as shown in this example.

The resulting tree represents the JSON data from JSON Syntax.

10.2.3 Navigating an Object Model

The following example shows a simple approach to navigating an object model:

```

import javax.json.JsonValue;
import javax.json.JsonObject;
import javax.json.JsonArray;
import javax.json.JsonNumber;
import javax.json.JsonString;
...
public static void navigateTree(JsonValue tree, String key) {
    if (key != null)
        System.out.print("Key " + key + ": ");
    switch (tree.getValueType()) {
        case OBJECT:
            System.out.println("OBJECT");
            JsonObject object = (JsonObject) tree;
            for (String name : object.keySet())
                navigateTree(object.get(name), name);
            break;
        case ARRAY:

```

```
        System.out.println("ARRAY");
        JSONArray array = (JSONArray) tree;
        for (JsonValue val : array)
            navigateTree(val, null);
        break;
    case STRING:
        JsonString st = (JsonString) tree;
        System.out.println("STRING " + st.getString());
        break;
    case NUMBER:
        JsonNumber num = (JsonNumber) tree;
        System.out.println("NUMBER " + num.toString());
        break;
    case TRUE:
    case FALSE:
    case NULL:
        System.out.println(tree.getValueType().toString());
        break;
    }
}
```

The `navigateTree` method can be used with the models shown in [Section 10.2.1, "Creating an Object Model from JSON Data"](#) and [Section 10.2.2, "Creating an Object Model from Application Code"](#) as follows:

```
navigateTree(model, null);
```

The `navigateTree` method takes two arguments: a JSON element and a key. The key is used only to help print the key-value pairs inside objects. Elements in a tree are represented by the `JsonValue` type. If the element is an object or an array, a new invocation to this method is made for every element contained in the object or array. If the element is a value, it is printed to standard output.

The `JsonValue.getValueType` method identifies the element as an object, an array, or a value. For objects, the `JsonObject.keySet` method returns a set of strings that contains the keys in the object, and the `JsonObject.get(String name)` method returns the value of the element whose key is `name`. For arrays, `JSONArray` implements the `List<JsonValue>` interface. You can use enhanced for loops with the `Set<String>` instance returned by `JsonObject.keySet` and with instances of `JSONArray`, as shown in this example.

The `navigateTree` method for the model shown in [Section 10.2.2, "Creating an Object Model from Application Code"](#) produces the following output:

```
OBJECT
Key firstName: STRING Duke
Key lastName: STRING Java
Key age: NUMBER 18
Key streetAddress: STRING 100 Internet Dr
Key city: STRING JavaTown
Key state: STRING JA
Key postalCode: STRING 12345
Key phoneNumbers: ARRAY
OBJECT
Key type: STRING mobile
Key number: STRING 111-111-1111
OBJECT
Key type: STRING home
Key number: STRING 222-222-2222
```

10.2.4 Writing an Object Model to a Stream

The object models created in [Section 10.2.1, "Creating an Object Model from JSON Data"](#) and [Section 10.2.2, "Creating an Object Model from Application Code"](#) can be written to a stream using the `javax.json.JsonWriter` interface as follows:

```
import java.io.StringWriter;
import javax.json.JsonWriter;
...
StringWriter stWriter = new StringWriter();
JsonWriter jsonWriter = Json.createWriter(stWriter);
jsonWriter.writeObject(model);
jsonWriter.close();

String jsonData = stWriter.toString();
System.out.println(jsonData);
```

The `Json.createWriter` method takes an output stream as a parameter. The `JsonWriter.writeObject` method writes the object to the stream. The `JsonWriter.close` method closes the underlying output stream.

The following example uses `try-with-resources` to close the JSON writer automatically:

```
StringWriter stWriter = new StringWriter();
try (JsonWriter jsonWriter = Json.createWriter(stWriter)) {
    jsonWriter.writeObject(model);
}

String jsonData = stWriter.toString();
System.out.println(jsonData);
```

10.3 Streaming API

The streaming API is a low-level API designed to process large amounts of JSON data efficiently. This API consists of the following interfaces:

Interface	Description
<code>javax.json.stream.JsonParser</code>	Contains methods to parse JSON in a streaming way. This interface provides forward, read-only access to JSON data using the pull parsing programming model. In this model the application code controls the thread and calls methods in the parser interface to move the parser forward or to obtain JSON data from the current state of the parser.
<code>javax.json.stream.JsonGenerator</code>	Contains methods to write JSON to an output source in a streaming way. This interface provides methods to write JSON to an output source. The generator writes name-value pairs in JSON objects and values in JSON arrays.

The following sections show examples of using the streaming API:

- [Reading JSON Data Using a Parser](#)
- [Writing JSON Data Using a Generator](#)

10.3.1 Reading JSON Data Using a Parser

The streaming API is the most efficient approach for parsing JSON text. The following example shows how to create a `JsonParser` object and how to parse JSON data using events:

```
import javax.json.Json;
import javax.json.stream.JsonParser;
...
JsonParser parser = Json.createParser(new StringReader(jsonData));
while (parser.hasNext()) {
    JsonParser.Event event = parser.next();
    switch(event) {
        case START_ARRAY:
        case END_ARRAY:
        case START_OBJECT:
        case END_OBJECT:
        case VALUE_FALSE:
        case VALUE_NULL:
        case VALUE_TRUE:
            System.out.println(event.toString());
            break;
        case KEY_NAME:
            System.out.print(event.toString() + " " +
                parser.getString() + " - ");
            break;
        case VALUE_STRING:
        case VALUE_NUMBER:
            System.out.println(event.toString() + " " +
                parser.getString());
            break;
    }
}
```

This example consists of three steps:

1. Obtain a parser instance by invoking the `Json.createParser` static method.
2. Iterate over the parser events using the `JsonParser.hasNext` and the `JsonParser.next` methods.
3. Perform local processing for each element.

The example shows the ten possible event types from the parser. The parser's `next` method advances it to the next event.

For the event types `KEY_NAME`, `VALUE_STRING`, and `VALUE_NUMBER`, you can obtain the content of the element by invoking the `JsonParser.getString` method.

For `VALUE_NUMBER` events, you can also use the following methods:

```
START_OBJECT
KEY_NAME firstName - VALUE_STRING Duke
KEY_NAME lastName - VALUE_STRING Java
KEY_NAME age - VALUE_NUMBER 18
KEY_NAME streetAddress - VALUE_STRING 100 Internet Dr
KEY_NAME city - VALUE_STRING JavaTown
KEY_NAME state - VALUE_STRING JA
KEY_NAME postalCode - VALUE_STRING 12345
KEY_NAME phoneNumbers - START_ARRAY
START_OBJECT
KEY_NAME type - VALUE_STRING mobile
KEY_NAME number - VALUE_STRING 111-111-1111
```

```
END_OBJECT
START_OBJECT
KEY_NAME type - VALUE_STRING home
KEY_NAME number - VALUE_STRING 222-222-2222
END_OBJECT
END_ARRAY
END_OBJECT
```

10.3.2 Writing JSON Data Using a Generator

The following example shows how to write JSON data to a file using the streaming API:

```
FileWriter writer = new FileWriter("test.txt");
JsonGenerator gen = Json.createGenerator(writer);
gen.writeStartObject()
    .write("firstName", "Duke")
    .write("lastName", "Java")
    .write("age", 18)
    .write("streetAddress", "100 Internet Dr")
    .write("city", "JavaTown")
    .write("state", "JA")
    .write("postalCode", "12345")
    .writeStartArray("phoneNumbers")
        .writeStartObject()
            .write("type", "mobile")
            .write("number", "111-111-1111")
        .writeEnd()
        .writeStartObject()
            .write("type", "home")
            .write("number", "222-222-2222")
        .writeEnd()
    .writeEnd()
.gen.writeEnd();
gen.close();
```

This example obtains a JSON generator by invoking the `Json.createGenerator` static method, which takes a writer or an output stream as a parameter. The example writes JSON data to the `test.txt` file by nesting invocations to the `write`, `writeStartArray`, `writeStartObject`, and `writeEnd` methods. The `JsonGenerator.close` method closes the underlying writer or output stream.

Understanding WebLogic Server Application Classloading

This chapter describes Java classloaders and WebLogic Server Java EE application classloading.

This chapter includes the following sections:

- [Section 11.1, "Java Classloading"](#)
- [Section 11.2, "WebLogic Server Application Classloading"](#)
- [Section 11.3, "Resolving Class References Between Modules and Applications"](#)
- [Section 11.4, "Using the Classloader Analysis Tool \(CAT\)"](#)
- [Section 11.5, "Sharing Applications and Modules By Using Java EE Libraries"](#)
- [Section 11.6, "Adding JARs to the Domain /lib Directory"](#)

11.1 Java Classloading

Classloaders are a fundamental module of the Java language. A classloader is a part of the Java virtual machine (JVM) that loads classes into memory; a classloader is responsible for finding and loading class files at run time. Every successful Java programmer needs to understand classloaders and their behavior. This section provides an overview of Java classloaders.

11.1.1 Java Classloader Hierarchy

Classloaders contain a hierarchy with parent classloaders and child classloaders. The relationship between parent and child classloaders is analogous to the object relationship of super classes and subclasses. The bootstrap classloader is the root of the Java classloader hierarchy. The Java virtual machine (JVM) creates the bootstrap classloader, which loads the Java development kit (JDK) internal classes and `java.*` packages included in the JVM. (For example, the bootstrap classloader loads `java.lang.String`.)

The extensions classloader is a child of the bootstrap classloader. The extensions classloader loads any JAR files placed in the extensions directory of the JDK. This is a convenient means to extending the JDK without adding entries to the classpath. However, anything in the extensions directory must be self-contained and can only refer to classes in the extensions directory or JDK classes.

The system classpath classloader extends the JDK extensions classloader. The system classpath classloader loads the classes from the classpath of the JVM.

Application-specific classloaders (including WebLogic Server classloaders) are children of the system classpath classloader.

Note: What Oracle refers to as a "system classpath classloader" is often referred to as the "application classloader" in contexts outside of WebLogic Server. When discussing classloaders in WebLogic Server, Oracle uses the term "system" to differentiate from classloaders related to Java EE applications or libraries (which Oracle refers to as "application classloaders").

11.1.2 Loading a Class

Classloaders use a delegation model when loading a class. The classloader implementation first checks its cache to see if the requested class has already been loaded. This class verification improves performance in that its cached memory copy is used instead of repeated loading of a class from disk. If the class is not found in its cache, the current classloader asks its parent for the class. Only if the parent cannot load the class does the classloader attempt to load the class. If a class exists in both the parent and child classloaders, the parent version is loaded. This delegation model is followed to avoid multiple copies of the same form being loaded. Multiple copies of the same class can lead to a `ClassCastException`.

Classloaders ask their parent classloader to load a class before attempting to load the class themselves. Classloaders in WebLogic Server that are associated with Web applications can be configured to check locally first before asking their parent for the class. This allows Web applications to use their own versions of third-party classes, which might also be used as part of the WebLogic Server product. The [Section 11.1.3, "prefer-web-inf-classes Element"](#) section discusses this in more detail.

11.1.3 prefer-web-inf-classes Element

The `weblogic.xml` Web application deployment descriptor contains a `<prefer-web-inf-classes>` element (a sub-element of the `<container-descriptor>` element). By default, this element is set to `False`. Setting this element to `True` subverts the classloader delegation model so that class definitions from the Web application are loaded in preference to class definitions in higher-level classloaders. This allows a Web application to use its own version of a third-party class, which might also be part of WebLogic Server. See "weblogic.xml Deployment Descriptor Elements".

When using this feature, you must be careful not to mix instances created from the Web application's class definition with instances created from the server's definition. If such instances are mixed, a `ClassCastException` results.

[Example 11-1](#) illustrates the `prefer-web-inf-classes` element, its description and default value.

Example 11-1 *prefer-web-inf-classes Element*

```
/**
 * If true, classes located in the WEB-INF directory of a web-app will be
 * loaded in preference to classes loaded in the application or system
 * classloader.
 * @default false
 */
boolean isPreferWebInfClasses();
void setPreferWebInfClasses(boolean b);
```

11.1.4 Changing Classes in a Running Program

WebLogic Server allows you to deploy newer versions of application modules such as EJBs while the server is running. This process is known as hot-deploy or hot-redeploy and is closely related to classloading.

Java classloaders do not have any standard mechanism to undeploy or unload a set of classes, nor can they load new versions of classes. In order to make updates to classes in a running virtual machine, the classloader that loaded the changed classes must be replaced with a new classloader. When a classloader is replaced, all classes that were loaded from that classloader (or any classloaders that are offspring of that classloader) must be reloaded. Any instances of these classes must be re-instantiated.

In WebLogic Server, each application has a hierarchy of classloaders that are offspring of the system classloader. These hierarchies allow applications or parts of applications to be individually reloaded without affecting the rest of the system. [Section 11.2, "WebLogic Server Application Classloading"](#) discusses this topic.

11.1.5 Class Caching With the Policy Classloader

The policy classloader is the default system class loader when starting WebLogic Server using a `startWebLogic` script. The policy classloader improves class loader performance and server startup time through class caching and indexing and is supported in any WebLogic mode (development or production).

The policy classloader caches loaded classes in a cache file. Upon subsequent starts, the cached classes are pre-loaded in bulk, improving performance in use cases that load a large number of classes from the system class loader, such as server startup. The policy classloader also contains an eager index, which maps package names and JAR files containing the source code. This index improves lookup time for classes and reduces the time spent looking for missing classes or resources. Cached files are generated in the `DOMAIN_HOME/servers/weblogic_name/cache/classloader` directory.

In WebLogic Server 12.1.3, you could enable class caching in development mode by setting the `CLASS_CACHE` environment variable in the `startWebLogic` script. For pre-existing 12.1.3 start scripts, continue to use the `CLASS_CACHE` variable to enable class caching. See "Configuring Class Caching" in *Developing Applications for Oracle WebLogic Server 12c (12.1.3)*.

As of WebLogic Server 12.2.1, new domains use the policy classloader by default for class caching. Any 12.1.3 domains that upgrade to 12.2.1 also automatically use the policy classloader.

11.2 WebLogic Server Application Classloading

The following sections provide an overview of the WebLogic Server application classloaders:

- [Section 11.2.1, "Overview of WebLogic Server Application Classloading"](#)
- [Section 11.2.2, "Application Classloader Hierarchy"](#)
- [Section 11.2.3, "Custom Module Classloader Hierarchies"](#)
- [Section 11.2.6, "Individual EJB Classloader for Implementation Classes"](#)
- [Section 11.2.7, "Application Classloading and Pass-by-Value or Reference"](#)
- [Section 11.2.8, "Using a Filtering ClassLoader"](#)

11.2.1 Overview of WebLogic Server Application Classloading

WebLogic Server classloading is centered on the concept of an application. An application is normally packaged in an Enterprise Archive (EAR) file containing application classes. Everything within an EAR file is considered part of the same application. The following may be part of an EAR or can be loaded as standalone applications:

- An Enterprise JavaBean (EJB) JAR file
- A Web application WAR file
- A resource adapter RAR file

Note: See the following sections for more information:

- For information on resource adapters and classloading, see [Section 11.3.1, "About Resource Adapter Classes"](#).
 - For information on overriding generic application files while classloading, see "Generic File Loading Overrides" in *Deploying Applications to Oracle WebLogic Server*.
-
-

If you deploy an EJB and a Web application separately, they are considered two applications. If they are deployed together within an EAR file, they are one application. You deploy modules together in an EAR file for them to be considered part of the same application.

Every application receives its own classloader hierarchy; the parent of this hierarchy is the system classpath classloader. This isolates applications so that application A cannot see the classloaders or classes of application B. In hierarchy classloaders, no sibling or friend concepts exist. Application code only has visibility to classes loaded by the classloader associated with the application (or module) and classes that are loaded by classloaders that are ancestors of the application (or module) classloader. This allows WebLogic Server to host multiple isolated applications within the same JVM.

11.2.2 Application Classloader Hierarchy

WebLogic Server automatically creates a hierarchy of classloaders when an application is deployed. The root classloader in this hierarchy loads any EJB JAR files in the application. A child classloader is created for each Web application WAR file.

Because it is common for Web applications to call EJBs, the WebLogic Server application classloader architecture allows JavaServer Page (JSP) files and servlets to see the EJB interfaces in their parent classloader. This architecture also allows Web applications to be redeployed without redeploying the EJB tier. In practice, it is more common to change JSP files and servlets than to change the EJB tier.

The following graphic illustrates this WebLogic Server application classloading concept.

Figure 11-1 WebLogic Server Classloading

If your application includes servlets and JSPs that use EJBs:

- Package the servlets and JSPs in a WAR file
- Package the Enterprise JavaBeans in an EJB JAR file
- Package the WAR and JAR files in an EAR file
- Deploy the EAR file

Although you could deploy the WAR and JAR files separately, deploying them together in an EAR file produces a classloader arrangement that allows the servlets and JSPs to find the EJB classes. If you deploy the WAR and JAR files separately, WebLogic Server creates sibling classloaders for them. This means that you must include the EJB home and remote interfaces in the WAR file, and WebLogic Server must use the RMI stub and skeleton classes for EJB calls, just as it does when EJB clients and implementation classes are in different JVMs. This concept is discussed in more detail in the next section [Section 11.2.7, "Application Classloading and Pass-by-Value or Reference"](#).

Note: The Web application classloader contains all classes for the Web application except for the JSP class. The JSP class obtains its own classloader, which is a child of the Web application classloader. This allows JSPs to be individually reloaded.

11.2.3 Custom Module Classloader Hierarchies

You can create custom classloader hierarchies for an application allowing for better control over class visibility and reloadability. You achieve this by defining a `classloader-structure` element in the `weblogic-application.xml` deployment descriptor file.

The following diagram illustrates how classloaders are organized by default for WebLogic applications. An application level classloader exists where all EJB classes are

loaded. For each Web module, there is a separate child classloader for the classes of that module.

For simplicity, JSP classloaders are not described in the following diagram.

Figure 11–2 Standard Classloader Hierarchy

This hierarchy is optimal for most applications, because it allows call-by-reference semantics when you invoke EJBs. It also allows Web modules to be independently reloaded without affecting other modules. Further, it allows code running in one of the Web modules to load classes from any of the EJB modules. This is convenient, as it can prevent a Web module from including the interfaces for EJBs that it uses. Note that some of those benefits are not strictly Java EE-compliant.

The ability to create custom module classloaders provides a mechanism to declare alternate classloader organizations that allow the following:

- Reloading individual EJB modules independently
- Reloading groups of modules to be reloaded together
- Reversing the parent child relationship between specific Web modules and EJB modules
- Namespace separation between EJB modules

11.2.4 Declaring the Classloader Hierarchy

You can declare the classloader hierarchy in the WebLogic-specific application deployment descriptor `weblogic-application.xml`.

The DTD for this declaration is as follows:

Example 11–2 Declaring the Classloader Hierarchy

```

<!ELEMENT classloader-structure (module-ref*, classloader-structure*)>
<!ELEMENT module-ref (module-uri)>
<!ELEMENT module-uri (#PCDATA)>
  
```

The top-level element in `weblogic-application.xml` includes an optional `classloader-structure` element. If you do not specify this element, then the standard classloader is used. Also, if you do not include a particular module in the definition, it is assigned a classloader, as in the standard hierarchy. That is, EJB modules are associated with the application root classloader, and Web application modules have their own classloaders.

The `classloader-structure` element allows for the nesting of `classloader-structure` stanzas, so that you can describe an arbitrary hierarchy of classloaders. There is currently a limitation of three levels. The outermost entry indicates the application classloader. For any modules not listed, the standard hierarchy is assumed.

Note: JSP classloaders are not included in this definition scheme. JSPs are always loaded into a classloader that is a child of the classloader associated with the Web module to which it belongs.

For more information on the DTD elements, refer to [Appendix A, "Enterprise Application Deployment Descriptor Elements."](#)

The following is an example of a classloader declaration (defined in the `classloader-structure` element in `weblogic-application.xml`):

Example 11-3 Example Classloader Declaration

```
<classloader-structure>
  <module-ref>
    <module-uri>ejb1.jar</module-uri>
  </module-ref>
  <module-ref>
    <module-uri>web3.war</module-uri>
  </module-ref>

  <classloader-structure>
    <module-ref>
      <module-uri>web1.war</module-uri>
    </module-ref>
  </classloader-structure>

  <classloader-structure>
    <module-ref>
      <module-uri>ejb3.jar</module-uri>
    </module-ref>
    <module-ref>
      <module-uri>web2.war</module-uri>
    </module-ref>

    <classloader-structure>
      <module-ref>
        <module-uri>web4.war</module-uri>
      </module-ref>
    </classloader-structure>
  </classloader-structure>
  <classloader-structure>
    <module-ref>
      <module-uri>ejb2.jar</module-uri>
    </module-ref>
  </classloader-structure>
</classloader-structure>
```

The organization of the nesting indicates the classloader hierarchy. The above stanza leads to a hierarchy shown in the following diagram.

Figure 11–3 Example Classloader Hierarchy

11.2.5 User-Defined Classloader Restrictions

User-defined classloader restrictions give you better control over what is reloadable and provide inter-module class visibility. This feature is primarily for developers. It is useful for iterative development, but the reloading aspect of this feature is not recommended for production use, because it is possible to corrupt a running application if an update includes invalid elements. Custom classloader arrangements for namespace separation and class visibility are acceptable for production use. However, programmers should be aware that the Java EE specifications say that applications should not depend on any given classloader organization.

Some classloader hierarchies can cause modules within an application to behave more like modules in two separate applications. For example, if you place an EJB in its own classloader so that it can be reloaded individually, you receive call-by-value semantics rather than the call-by-reference optimization Oracle provides in our standard classloader hierarchy. Also note that if you use a custom hierarchy, you might end up with stale references. Therefore, if you reload an EJB module, you should also reload the calling modules.

There are some restrictions to creating user-defined module classloader hierarchies; these are discussed in the following sections.

11.2.5.1 Servlet Reloading Disabled

If you use a custom classloader hierarchy, servlet reloading is disabled for Web applications in that particular application.

11.2.5.2 Nesting Depth

Nesting is limited to three levels (including the application classloader). Deeper nestings lead to a deployment exception.

11.2.5.3 Module Types

Custom classloader hierarchies are currently restricted to Web and EJB modules.

11.2.5.4 Duplicate Entries

Duplicate entries lead to a deployment exception.

11.2.5.5 Interfaces

The standard WebLogic Server classloader hierarchy makes EJB interfaces available to all modules in the application. Thus other modules can invoke an EJB, even though they do not include the interface classes in their own module. This is possible because EJBs are always loaded into the root classloader and all other modules either share that classloader or have a classloader that is a child of that classloader.

With the custom classloader feature, you can configure a classloader hierarchy so that a callee's classes are not visible to the caller. In this case, the calling module must include the interface classes. This is the same requirement that exists when invoking on modules in a separate application.

11.2.5.6 Call-by-Value Semantics

The standard classloader hierarchy provided with WebLogic Server allows for calls between modules within an application to use call-by-reference semantics. This is because the caller is always using the same classloader or a child classloader of the callee. With this feature, it is possible to configure the classloader hierarchy so that two modules are in separate branches of the classloader tree. In this case, call-by-value semantics are used.

11.2.5.7 In-Flight Work

Be aware that the classloader switch required for reloading is not atomic across modules. In fact, updates to applications in general are not atomic. For this reason, it is possible that different in-flight operations (operations that are occurring while a change is being made) might end up accessing different versions of classes depending on timing.

11.2.5.8 Development Use Only

The development-use-only feature is intended for development use. Because updates are not atomic, this feature is not suitable for production use.

11.2.6 Individual EJB Classloader for Implementation Classes

WebLogic Server allows you to reload individual EJB modules without requiring you to reload other modules at the same time and having to redeploy the entire EJB module. This feature is similar to how JSPs are currently reloaded in the WebLogic Server servlet container.

Because EJB classes are invoked through an interface, it is possible to load individual EJB implementation classes in their own classloader. This way, these classes can be reloaded individually without having to redeploy the entire EJB module. Below is a diagram of what the classloader hierarchy for a single EJB module would look like. The module contains two EJBs (`Foo` and `Bar`). This would be a sub-tree of the general application hierarchy described in the previous section.

Figure 11-4 Example Classloader Hierarchy for a Single EJB Module

To perform a partial update of files relative to the root of the exploded application, use the following command line:

Example 11-4 Performing a Partial File Update

```
java weblogic.Deployer -adminurl url -user user -password password
-name myapp -redeploy myejb/foo.class
```

After the `-redeploy` command, you provide a list of files relative to the root of the exploded application that you want to update. This might be the path to a specific element (as above) or a module (or any set of elements and modules). For example:

Example 11-5 Providing a List of Relative Files for Update

```
java weblogic.Deployer -adminurl url -user user -password password
-name myapp -redeploy mywar myejb/foo.class anotherjeb
```

Given a set of files to be updated, the system tries to figure out the minimum set of things it needs to redeploy. Redeploying only an EJB `impl` class causes only that class to be redeployed. If you specify the whole EJB (in the above example, `anotherjeb`) or if you change and update the EJB home interface, the entire EJB module must be redeployed.

Depending on the classloader hierarchy, this redeployment may lead to other modules being redeployed. Specifically, if other modules share the EJB classloader or are loaded into a classloader that is a child to the EJB's classloader (as in the WebLogic Server standard classloader module) then those modules are also reloaded.

11.2.7 Application Classloading and Pass-by-Value or Reference

Modern programming languages use two common parameter passing models: pass-by-value and pass-by-reference. With pass-by-value, parameters and return values are copied for each method call. With pass-by-reference, a pointer (or reference) to the actual object is passed to the method. Pass by reference improves performance because it avoids copying objects, but it also allows a method to modify the state of a passed parameter.

WebLogic Server includes an optimization to improve the performance of Remote Method Interface (RMI) calls within the server. Rather than using pass by value and the RMI subsystem's marshalling and unmarshalling facilities, the server makes a direct Java method call using pass by reference. This mechanism greatly improves performance and is also used for EJB 2.0 local interfaces.

RMI call optimization and call by reference can only be used when the caller and callee are within the same application. As usual, this is related to classloaders. Because applications have their own classloader hierarchy, any application class has a definition in both classloaders and receives a `ClassCastException` error if you try to assign between applications. To work around this, WebLogic Server uses call-by-value between applications, even if they are within the same JVM.

Note: Calls between applications are slower than calls within the same application. Deploy modules together as an EAR file to enable fast RMI calls and use of the EJB 2.0 local interfaces.

11.2.8 Using a Filtering ClassLoader

In WebLogic Server, any JAR file present in the system classpath is loaded by the WebLogic Server system classloader. All applications running within a server instance are loaded in application classloaders which are children of the system classloader. In this implementation of the system classloader, applications cannot use different versions of third-party JARs which are already present in the system classloader. Every child classloader asks the parent (the system classloader) for a particular class and cannot load classes which are seen by the parent.

For example, if a class called `com.foo.Baz` exists in both `$CLASSPATH` as well as the application EAR, then the class from the `$CLASSPATH` is loaded and not the one from the EAR. Since `weblogic.jar` is in the `$CLASSPATH`, applications can not override any WebLogic Server classes.

The following sections define and describe how to use a filtering classloader:

- [Section 11.2.9, "What is a Filtering ClassLoader"](#)
- [Section 11.2.10, "Configuring a Filtering ClassLoader"](#)
- [Section 11.2.11, "Resource Loading Order"](#)

11.2.9 What is a Filtering ClassLoader

The `FilteringClassLoader` provides a mechanism for you to configure deployment descriptors to explicitly specify that certain packages should always be loaded from the application, rather than being loaded by the system classloader. This allows you to use alternate versions of applications such as Xerces and Ant. Though the `FilteringClassLoader` lets you bundle and use 3rd party JARs in your application, it is not recommended that you filter out API classes, like classes in `javax` packages or `weblogic` packages.

The `FilteringClassLoader` sits between the application classloader and the system classloader. It is a child of the system classloader and the parent of the application classloader. The `FilteringClassLoader` intercepts the `loadClass(String className)` method and compares the `className` with a list of packages specified in `weblogic-application.xml` file. If the package matches the `className`, the `FilteringClassLoader` throws a `ClassNotFoundException`. This exception notifies the application classloader to load this class from the application.

11.2.10 Configuring a Filtering ClassLoader

To configure the `FilteringClassLoader` to specify that a certain package is loaded from an application, add a `prefer-application-packages` descriptor element to `weblogic-application.xml` which details the list of packages to be loaded from the application. The following example specifies that `org.apache.log4j.*` and `antlr.*` packages are loaded from the application, not the system classloader:

```
<prefer-application-packages>
  <package-name>org.apache.log4j.*</package-name>
  <package-name>antlr.*</package-name>
</prefer-application-packages>
```

The `prefer-application-packages` descriptor element can also be defined in `weblogic.xml`. For more information, see "prefer-application-packages".

You can specify that a certain package be loaded for a WAR file included within an EAR file by configuring the `FilteringClassLoader` in the `weblogic.xml` file of the WAR file.

For example, `A.ear` contains `B.war`. `A.ear` defines the `FilteringClassLoader` in `weblogic-application.xml`, and `B.war` defines a different `FilteringClassLoader` in `weblogic.xml`. When you deploy `A.ear`, `B.war` loads the package defined in the `FilteringClassLoader` in `weblogic.xml`. The WAR-level `FilteringClassLoader` has priority over the EAR-level `FilteringClassLoader` for this WAR file.

For aid in configuring filtering classloaders, see [Section 11.4, "Using the Classloader Analysis Tool \(CAT\)."](#)

11.2.11 Resource Loading Order

The resource loading order is the order in which `java.lang.ClassLoader` methods `getResource()` and `getResources()` return resources. When filtering is enabled, this order is slightly different from the case when filtering is disabled. Filtering is enabled implies that there are one or more package patterns in the `FilteringClassLoader`. Without any filtering (default), the resources are collected in the top-down order of the classloader tree. For instance, if Web (1) requests resources, the resources are grouped in the following order: Sys (3), App (2) and Web(1). See [Example 11-6](#).

Example 11-6 Using the System Classloader

```
System (3)
  |
  App (2)
  |
  Web (1)
```

To be more explicit, given a resource `/META-INF/foo.xml` which exists in all the classloaders, would return the following list of URLs:

```
META-INF/foo.xml - from the System ClassLoader (3)
META-INF/foo.xml - from the App ClassLoader (2)
META-INF/foo.xml - from the Web ClassLoader (1)
```

When filtering is enabled, the resources from the child of the `FilteringClassLoader` (an application classloader) down to the calling classloader are returned before the ones from the system classloader. In [Example 11-7](#), if the same resource existed in all the classloaders (D), (B) and (A) one would get them in the following order if requested by the Web classloader:

```

META-INF/foo.xml - from the App ClassLoader (B)
META-INF/foo.xml - from the Web ClassLoader (A)
META-INF/foo.xml - from the System ClassLoader (D)

```

Note: The resources are returned in the default Java EE delegation model beneath the `FilteringClassLoader`. Only the resources from the parent of the `FilteringClassLoader` are appended to the end of the enumeration being returned.

Example 11-7 Using a Filtering Classloading Implementation

```

System (D)
|
FilteringClassLoader (filterList := x.y.*) (C)
|
App (B)
|
Web (A)

```

If the application classloader requested the same resource, the following order would be obtained.

```

META-INF/foo.xml - from the App ClassLoader (B)
META-INF/foo.xml - from the System ClassLoader (D)

```

For `getResource()`, only the first descriptor is returned and `getResourceAsStream()` returns the `InputStream` of the first resource.

11.3 Resolving Class References Between Modules and Applications

Your applications may use many different Java classes, including Enterprise Beans, servlets and JavaServer Pages, utility classes, and third-party packages. WebLogic Server deploys applications in separate classloaders to maintain independence and to facilitate dynamic redeployment and undeployment. Because of this, you need to package your application classes in such a way that each module has access to the classes it depends on. In some cases, you may have to include a set of classes in more than one application or module. This section describes how WebLogic Server uses multiple classloaders so that you can stage your applications successfully.

For more information about analyzing and resolving classloading issues, see [Section 11.4, "Using the Classloader Analysis Tool \(CAT\)."](#)

11.3.1 About Resource Adapter Classes

Each resource adapter uses its own classloader to load classes (similar to Web applications). In previous releases, modules like Web applications and EJBs that are packaged along with a resource adapter in an application archive (EAR file) do not have visibility into the resource adapter's classes. If such visibility is required, you must place the resource adapter classes in `APP-INF/classes`. You can also archive these classes (using the JAR utility) and place them in the `APP-INF/lib` of the application archive.

In WebLogic Server 12.2.1 release, the classloader of the application archive (EAR) loads the resource adapter class by default. The **Enable EE Compliant Class loading for Embedded Adapters** configuration option for a domain on the WebLogic Server Administration Console determines this classloading behavior of embedded adapters. This option is enabled by default. Disable this option for pre-12.2.1 classloading

behavior of resource adapters. For more information, see the online help for "Domains: Configuration: General" page in *Oracle WebLogic Server Administration Console Online Help*.

Note: When the `<enable-global-access-to-classes>` element in the `weblogic-ra.xml` deployment descriptor is set to `true`, the EE compliant classloader setting in the domain configuration is ignored. For more information, see "weblogic-ra.xml Schema" in *Developing Resource Adapters for Oracle WebLogic Server*.

Make sure that no resource-adapter specific classes exist in your WebLogic Server system classpath. If you need to use resource adapter-specific classes with Web modules (for example, an EJB or Web application), you must bundle these classes in the corresponding module's archive file (for example, the JAR file for EJBs or the WAR file for Web applications).

11.3.2 Packaging Shared Utility Classes

WebLogic Server provides a location within an EAR file where you can store shared utility classes. Place utility JAR files in the `APP-INF/lib` directory and individual classes in the `APP-INF/classes` directory. (Do not place JAR files in the `/classes` directory or classes in the `/lib` directory.) These classes are loaded into the root classloader for the application.

This feature obviates the need to place utility classes in the system classpath or place classes in an EJB JAR file (which depends on the standard WebLogic Server classloader hierarchy). Be aware that using this feature is subtly different from using the manifest `Class-Path` described in the following section. With this feature, class definitions are shared across the application. With manifest `Class-Path`, the classpath of the referencing module is simply extended, which means that separate copies of the classes exist for each module.

11.3.3 Manifest Class-Path

The Java EE specification provides the manifest `Class-Path` entry as a means for a module to specify that it requires an auxiliary JAR of classes. You only need to use this manifest `Class-Path` entry if you have additional supporting JAR files as part of your EJB JAR or WAR file. In such cases, when you create the JAR or WAR file, you must include a manifest file with a `Class-Path` element that references the required JAR files.

The following is a simple manifest file that references a `utility.jar` file:

```
Manifest-Version: 1.0 [CRLF]
Class-Path: utility.jar [CRLF]
```

In the first line of the manifest file, you must always include the `Manifest-Version` attribute, followed by a new line (CR | LF | CRLF) and then the `Class-Path` attribute. More information about the manifest format can be found at:

<http://docs.oracle.com/javase/8/docs/technotes/guides/jar/jar.html>

The manifest `Class-Path` entries refer to other archives relative to the current archive in which these entries are defined. This structure allows multiple WAR files and EJB JAR files to share a common library JAR. For example, if a WAR file contains a manifest entry of `y.jar`, this entry should be next to the WAR file (not within it) as follows:

```

/<directory>/x.war
/<directory>/y.jars

```

The manifest file itself should be located in the archive at `META-INF/MANIFEST.MF`.

For more information, see

<http://docs.oracle.com/javase/tutorial/deployment/jar/manifestindex.html>.

11.4 Using the Classloader Analysis Tool (CAT)

CAT is a Web-based class analysis tool that aids you in analyzing classloading configuration and aids you in analyzing classloading issues, such as detecting conflicts, debugging application classpaths and class conflicts, and proposes filtering configuration suggestions to help you resolve such conflicts.

CAT is a stand-alone Web application, distributed as a single WAR file, `wls-cat.war`, exposing its features through a Web-based front end. CAT is deployed as an internal on-demand application only in development mode. Deployment happens upon first access. If the server is running in production mode, it is not deployed automatically. You can deploy it in production mode; there are no limitations on its use, but you must deploy it manually, just like any other Web application. CAT is located at `WL_HOME/server/lib/wls-cat.war`.

CAT can also be deployed on-demand to a WebLogic domain partition by accessing the partition-specific URL of the CAT web application, and then only applications deployed to that domain partition will be analyzed by CAT.

Note: CAT is not supported on IBM SDK for Java because some functions of the CAT application depend on HotSpot implementation.

11.4.1 Opening the CAT Interface

CAT has a simple Web GUI that displays all your currently running applications and modules.

To begin using CAT:

- Point your browser to `http://wls-host:port:wls-cat/` and then enter your console login credentials.

When CAT needs to be accessed for a particular domain partition, point your browser to the partition-specific URL. For example, `http://wls-host:partition_port/partition_uri/wls-cat/`, where *partition* is the URI prefix for the partition.

~ Or ~

- In the Administration Console, select **Deployments** > *app_name* > **Testing**, and then select the **Classloader Analysis Tool** link. Enter your console login credentials.

When CAT needs to be accessed for a particular domain partition, select **Domain Partitions** > *partition_name* > **Deployments** > *app_name* > **Testing**, and then select the **Classloader Analysis Tool** link.

In the navigation pane, select the application or module that you want to analyze; a brief description of it is shown in the right-side pane. Use the right-side pane to perform actions and analyses on the selected application or module, such as:

- Analyze classloading conflicts

- View the system and application classloaders
- Generate reports

11.4.2 How CAT Analyzes Classes

CAT analyzes classes loaded by the system classpath classloader and the WebLogic Server main application classloaders, defined here as the module, application, partition, and shared-application classloaders. You can perform analysis at the class, package, or JAR level. The results for each action you select can be shown in either a basic view or a detailed view.

Note: Starting in this release of Oracle WebLogic Server 12c (12.2.1), there is no separate class loader called *filtering class loader*; however, module, application and shared-application class loaders are capable of filtering. Configuring filtering using deployment descriptors remains the same.

Here are some of the tasks which you can perform using CAT:

- Display basic information about applications and modules
- Analyze classloading conflicts
- Review proposed solutions
- Get suggestions for configuring filtering
- Display the classloader hierarchy and the entire classpath for each classloader
- Search for a class (or a resource) on a classloader

11.4.3 Identifying Class References through Manifest Hierarchies

Applications can have multiple manifest references to classes that are not directly present in the applications's classpath, but which are *chained* into the Classpath by manifest references. In some cases, application developers may not be aware that additional classes have been unknowingly pulled into the application's classpath from other JARs, which in turn have manifest references to other JARs.

CAT has the ability to search through an application's or module's classpath to detect and display the underlying chained manifest references, as shown in the following example:

Example 11–8 Sample EAR with Manifest Hierarchies

```
cat4mf.ear
+- ejb.jar
+- web-mf-in-root.war
+- lib
    +- applib.jar
+- apputil_1.jar
+- apputil_1_1.jar
+- apputil_1_1_1.jar
+- apputil_1_2.jar
+- apputil_1_2_1.jar
+- ejbutil_1.jar
+- ejbutil_1_1.jar
+- ejbutil_1_2.jar
+- ejbutil_1_2_1.jar
```

```

+- webutil_1.jar
+- webutil_1_1.jar
+- webutil_1_1_1.jar
+- webutil_2.jar
+- webutil_2_1.jar

```

The `ejb.jar` has a manifest reference to `ejbutil_1.jar`, which has references to both `ejbutil_1_1.jar` and `ejbutil_1_2.jar`, which has a further reference to `ejbutil_1_2_1.jar`, as follows:

```

ejb.jar
-> ejbutil_1.jar
    -> ejbutil_1_1.jar
    -> ejbutil_1_2.jar
        -> ejbutil_1_2_1.jar

```

Using CAT to Display the Manifest References

1. Open the CAT tool, as described in [Section 11.4.1, "Opening the CAT Interface."](#)
2. Use the navigation pane to select the running application or module to analyze.

Note: The manifest references can best be analyzed from the module level rather than the application level.
3. In the **Summary for Application** pane, click the **Classloader Tree** view to list all the classloaders for the selected application/module.
 - Selecting the **detailed** view from the menu displays the classpath of each classloader.
 - The hash code of each classloader is an active URL.
4. Click the classloader hash code URL you want to analyze.
5. The **Classloader** page defaults to the basic view, so select the **detailed** view to see the classpath and the classes loaded by the classloader.
6. Enter one of the loaded classnames in the **Resource to analyze** field (using the format `pckgname.classname`), and click **Analyze Resource**.
7. The **Manifest References** section of the detailed output provides the list of chained manifest references for the selected classname.

Continuing with [Example 11–8](#), the output should look like this:

```

path/to/user_projects/applications/cat4mf/y79s0z/ejb.jar
  path/to/user_projects/applications/cat4mf/y79s0z/ejbutil_1.jar
    path/to/user_projects/applications/cat4mf/y79s0z/ejbutil_1_2.jar
      path/to/user_projects/applications/cat4mf/y79s0z/ejbutil_1_2_1.jar

```

11.5 Sharing Applications and Modules By Using Java EE Libraries

Java EE libraries provide an easy way to share one or more different types of Java EE modules among multiple enterprise applications. A Java EE library is a single module or collection of modules that is registered with the Java EE application container upon deployment. For more information, see [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."](#)

11.6 Adding JARs to the Domain /lib Directory

WebLogic Server includes a `lib` subdirectory, located in the domain directory, that you can use to add one or more JAR files, so that the JAR file classes are available (within a separate system level classloader) to all Java EE applications running on WebLogic Server instances in the domain. The JARS in the domain `/lib` directory will not be appended to the system classpath. The classloader that gets created is a child of the system classloader. Any classes that are in JARs in the domain `/lib` directory will only be visible to Java EE applications, such as EAR files. Classes in the system classpath cannot access classes in the domain `/lib` directory.

The `lib` subdirectory is intended for JAR files that change infrequently and are required by all or most applications deployed in the server. For example, you might use the `lib` directory to store third-party utility classes that are required by all Java EE deployments in a domain. Third-party utility classes will be made available because the domain `/lib` classloader will be the parent of any Java EE application.

The `lib` directory is not recommended as a general-purpose method for sharing a JARs between one or two applications deployed in a domain, or for sharing JARs that need to be updated periodically. If you update a JAR in the `lib` directory, you must reboot all servers in the domain in order for applications to realize the change. If you need to share a JAR file or Java EE modules among several applications, use the Java EE libraries feature described in [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."](#)

To share JARs using the `lib` directory:

1. Shutdown all servers in the domain.
2. Copy the JAR file(s) to share into a `lib` subdirectory of the domain directory. For example:

```
mkdir DOMAIN_HOME\wl_server\lib
cp c:\3rdpartyjars\utility.jar
   DOMAIN_HOME\wl_server\lib
```

Note: WebLogic Server must have read access to the `lib` directory during startup.

The Administration Server does not automatically copy files in the `lib` directory to Managed Servers on remote machines. If you have Managed Servers that do not share the same physical domain directory as the Administration Server, you must manually copy JAR file(s) to the `domain_name/lib` directory on the Managed Server machines.

3. Start the Administration Server and all Managed Servers in the domain.

Creating Shared Java EE Libraries and Optional Packages

This chapter describes how to share components and classes among applications using shared Java EE libraries and optional packages supported in WebLogic Server.

This chapter includes the following sections:

- [Section 12.1, "Overview of Shared Java EE Libraries and Optional Packages"](#)
- [Section 12.2, "Creating Shared Java EE Libraries"](#)
- [Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application"](#)
- [Section 12.4, "Referencing Optional Packages from a Java EE Application or Module"](#)
- [Section 12.5, "Using weblogic.appmerge to Merge Libraries"](#)
- [Section 12.6, "Integrating Shared Java EE Libraries with the Split Development Directory Environment"](#)
- [Section 12.7, "Deploying Shared Java EE Libraries and Dependent Applications"](#)
- [Section 12.8, "Web Application Shared Java EE Library Information"](#)
- [Section 12.9, "Using WebApp Libraries With Web Applications"](#)
- [Section 12.10, "Accessing Registered Shared Java EE Library Information with LibraryRuntimeMBean"](#)
- [Section 12.11, "Order of Precedence of Modules When Referencing Shared Java EE Libraries"](#)
- [Section 12.12, "Best Practices for Using Shared Java EE Libraries"](#)

12.1 Overview of Shared Java EE Libraries and Optional Packages

The shared Java EE library feature in WebLogic Server provides an easy way to share one or more different types of Java EE modules among multiple enterprise applications. A shared Java EE library is a single module or collection of modules that is registered with the Java EE application container upon deployment. A shared Java EE library can be any of the following:

- standalone EJB module
- standalone Web application module
- multiple EJB modules packaged in an enterprise application
- multiple Web application modules package in an enterprise application

- single plain JAR file

Oracle recommends that you package a shared Java EE library into its appropriate archive file (EAR, JAR, or WAR). However, for development purposes, you may choose to deploy shared Java EE libraries as exploded archive directories to facilitate repeated updates and redeployments.

After the shared Java EE library has been registered, you can deploy enterprise applications that reference the library. Each referencing application receives a reference to the required library on deployment, and can use the modules that make up the library as if they were packaged as part of the referencing application itself. The library classes are added to the classpath of the referencing application, and the referencing application's deployment descriptors are merged (in memory) with those of the modules that make up the shared Java EE library.

In general, this topic discusses shared Java EE libraries that can be referenced only by enterprise applications. You can also create libraries that can be referenced only by another Web application. The functionality is very similar to application libraries, although the method of referencing them is slightly different. See [Section 12.8, "Web Application Shared Java EE Library Information"](#) for details.

Note: WebLogic Server also provides a simple way to add one or more JAR files to the WebLogic Server System classpath, using the `lib` subdirectory of the domain directory. See [Section 11.6, "Adding JARs to the Domain /lib Directory"](#).

12.1.1 Optional Packages

WebLogic Server supports optional packages as described at <http://docs.oracle.com/javase/8/docs/technotes/guides/extensions/extensions.html> with versioning described in [Optional Package Versioning](http://docs.oracle.com/javase/8/docs/technotes/guides/extensions/versioning.html) (see <http://docs.oracle.com/javase/8/docs/technotes/guides/extensions/versioning.html>). Optional packages provide similar functionality to Java EE libraries, allowing you to easily share a single JAR file among multiple applications. As with Java EE libraries, optional packages must first be registered with WebLogic Server by deploying the associated JAR file as an optional package. After registering the package, you can deploy Java EE modules that reference the package in their manifest files.

Optional packages are also supported as Java EE shared libraries in `weblogic.BuildXMLGen`, whereby all manifests of an application and its modules are scanned to look for optional package references. If optional package references are found they are added to the `wlcompile` and `appc` tasks in the generated `build.xml` file.

Optional packages differ from Java EE libraries because optional packages can be referenced from any Java EE module (EAR, JAR, WAR, or RAR archive) or exploded archive directory. Java EE libraries can be referenced only from a valid enterprise application.

For example, third-party Web application Framework classes needed by multiple Web applications can be packaged and deployed in a single JAR file, and referenced by multiple Web application modules in the domain. Optional packages, rather than Java EE libraries, are used in this case, because the individual Web application modules must reference the shared JAR file. (With Java EE libraries, only a complete enterprise application can reference the library).

Note: Oracle documentation and WebLogic Server utilities use the term *library* to refer to both Java EE libraries and optional packages. Optional packages are called out only when necessary.

12.1.2 Library Directories

The Java EE platform provides several mechanisms for applications to use optional packages and shared libraries. Libraries can be bundled with an application or may be installed separately for use by any application. An EAR file may contain a directory that contains libraries packaged in JAR files. The `library-directory` element of the EAR file's deployment descriptor contains the name of this directory. If a `library-directory` element isn't specified, or if the EAR file does not contain a deployment descriptor, the directory named `lib` is used. An empty `library-directory` element may be used to specify that there is no library directory. All files in this directory (but not in subdirectories) with a `.jar` extension must be made available to all components packaged in the EAR file, including application clients. These libraries may reference other libraries, either bundled with the application or installed separately.

This feature is similar to the `APP-INF/lib` feature supported in WebLogic Server. If both `APP-INF/lib` and `library-directory` exist, then the jars in the `library-directory` would take precedence; that is, they would be placed before the `APP-INF/lib` jar files in the classpath. For more information on `APP-INF/lib`, see [Section 11.3, "Resolving Class References Between Modules and Applications"](#) and [Section 4.4, "Organizing Shared Classes in a Split Development Directory"](#).

12.1.3 Versioning Support for Libraries

WebLogic Server supports versioning of shared Java EE libraries, so that referencing applications can specify a required minimum version of the library to use, or an exact, required version. WebLogic Server supports two levels of versioning for shared Java EE libraries, as described in the Optional Package Versioning document at <http://docs.oracle.com/javase/8/docs/technotes/guides/extensions/versioning.html>:

- **Specification Version**—Identifies the version number of the specification (for example, the Java EE specification version) to which a shared Java EE library or optional package conforms.
- **Implementation Version**—Identifies the version number of the actual code implementation for the library or package. For example, this would correspond to the actual revision number or release number of your code. Note that you must also provide a specification version in order to specify an implementation version.

As a best practice, Oracle recommends that you always include version information (a specification version, or both an implementation and specification version) when creating shared Java EE libraries. Creating and updating version information as you develop shared components allows you to deploy multiple versions of those components simultaneously for testing. If you include no version information, or fail to increment the version string, then you must undeploy existing libraries before you can deploy the newer one. See [Section 12.7, "Deploying Shared Java EE Libraries and Dependent Applications"](#).

Versioning information in the referencing application determines the library and package version requirements for that application. Different applications can require different versions of a given library or package. For example, a production application may require a specific version of a library, because only that library has been fully

approved for production use. An internal application may be configured to always use a minimum version of the same library. Applications that require no specific version can be configured to use the latest version of the library. [Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application"](#).

12.1.4 Shared Java EE Libraries and Optional Packages Compared

Optional packages and shared Java EE libraries have the following features in common:

- Both are registered with WebLogic Server instances at deployment time.
- Both support an optional implementation version and specification version string.
- Applications that reference shared Java EE libraries and optional packages can specify required versions for the shared files.
- Optional packages can reference other optional packages, and shared Java EE libraries can reference other shared Java EE libraries.

Optional packages differ from shared Java EE Libraries in the following basic ways:

- Optional packages are plain JAR files, whereas shared Java EE libraries can be plain JAR files, Java EE enterprise applications, or standalone Java EE modules (EJB and Web applications). This means that libraries can have valid Java EE and WebLogic Server deployment descriptors. Any deployment descriptors in an optional package JAR file are ignored.
- Any Java EE application or module can reference an optional package (using `META-INF/MANIFEST.MF`), whereas only enterprise applications and Web applications can reference a shared Java EE library (using `weblogic-application.xml` or `weblogic.xml`).

In general, use shared Java EE libraries when you need to share one or more EJB, Web application or enterprise application modules among different enterprise applications. Use optional packages when you need to share one or more classes (packaged in a JAR file) among different Java EE modules.

Plain JAR files can be shared either as libraries or optional packages. Use optional packages if you want to:

- Share a plain JAR file among multiple Java EE modules
- Reference shared JAR files from other shared JARs
- Share plain JARs as described by the Java EE 5.0 specification

Use shared Java EE libraries to share a plain JAR file if you only need to reference the JAR file from one or more enterprise applications, and you do not need to maintain strict compliance with the Java EE specification.

Note: Oracle documentation and WebLogic Server utilities use the term *shared Java EE library* to refer to both libraries and optional packages. Optional packages are called out only when necessary.

12.1.5 Additional Information

For information about deploying and managing shared Java EE libraries, optional packages, and referencing applications from the administrator's perspective, see "Deploying Shared Java EE Libraries and Dependent Applications" in *Deploying Applications to Oracle WebLogic Server*.

12.2 Creating Shared Java EE Libraries

To create a new shared Java EE library that you can share with multiple applications:

1. Assemble the shared Java EE library into a valid, deployable Java EE module or enterprise application. The library must have the required Java EE deployment descriptors for the Java EE module or for an enterprise application.

See [Section 12.2.1, "Assembling Shared Java EE Library Files"](#).

2. Assemble optional package classes into a working directory.

See [Section 12.2.2, "Assembling Optional Package Class Files"](#).

3. Create and edit the `MANIFEST.MF` file for the shared Java EE library to specify the name and version string information.

See [Section 12.2.3, "Editing Manifest Attributes for Shared Java EE Libraries"](#).

4. Package the shared Java EE library for distribution and deployment.

See [Section 12.2.4, "Packaging Shared Java EE Libraries for Distribution and Deployment"](#).

12.2.1 Assembling Shared Java EE Library Files

The following types of Java EE modules can be deployed as a shared Java EE library:

- An EJB module, either an exploded directory or packaged in a JAR file.
- A Web application module, either an exploded directory or packaged in a WAR file.
- An enterprise application, either an exploded directory or packaged in an EAR file.
- A plain Java class or classes packaged in a JAR file.
- A shared Java EE library referenced from another library. (See [Section 12.8, "Web Application Shared Java EE Library Information"](#).)

Shared Java EE libraries have the following restrictions:

- You must ensure that context roots in Web application modules of the shared Java EE library do not conflict with context roots in the referencing enterprise application. If necessary, you can configure referencing applications to override a library's context root. See [Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application"](#).
- Shared Java EE libraries cannot be nested. For example, if you are deploying an EAR as a shared Java EE library, the entire EAR must be designated as the library. You cannot designate individual Java EE modules within the EAR as separate, named libraries.
- As with any other Java EE module or enterprise application, a shared Java EE library must be configured for deployment to the target servers or clusters in your domain. This means that a library requires valid Java EE deployment descriptors as well as WebLogic Server-specific deployment descriptors and an optional deployment plan. See *Deploying Applications to Oracle WebLogic Server*.

Oracle recommends packaging shared Java EE libraries as enterprise applications, rather than as standalone Java EE modules. This is because the URI of a standalone module is derived from the deployment name, which can change depending on how the module is deployed. By default, WebLogic Server uses the deployment archive

filename or exploded archive directory name as the deployment name. If you redeploy a standalone shared Java EE library from a different file or location, the deployment name and URI also change, and referencing applications that use the wrong URI cannot access the deployed library.

If you choose to deploy a shared Java EE library as a standalone Java EE module, always specify a known deployment name during deployment and use that name as the URI in referencing applications.

12.2.2 Assembling Optional Package Class Files

Any set of classes can be organized into an optional package file. The collection of shared classes will eventually be packaged into a standard JAR archive. However, because you will need to edit the manifest file for the JAR, begin by assembling all class files into a working directory:

1. Create a working directory for the new optional package. For example:

```
mkdir /apps/myOptPkg
```

2. Copy the compiled class files into the working directory, creating the appropriate package subdirectories as necessary. For example:

```
mkdir -p /apps/myOptPkg/org/myorg/myProduct  
cp /build/classes/myOptPkg/org/myOrg/myProduct/*.class  
/apps/myOptPkg/org/myOrg/myProduct
```

3. If you already have a JAR file that you want to use as an optional package, extract its contents into the working directory so that you can edit the manifest file:

```
cd /apps/myOptPkg  
jar xvf /build/libraries/myLib.jar
```

12.2.3 Editing Manifest Attributes for Shared Java EE Libraries

The name and version information for a shared Java EE library are specified in the `META-INF/MANIFEST.MF` file. [Table 12-1](#) describes the valid shared Java EE library manifest attributes.

Table 12–1 Manifest Attributes for Java EE Libraries

Attribute	Description
Extension-Name	<p>An optional string value that identifies the name of the shared Java EE library. Referencing applications must use the exact <code>Extension-Name</code> value to use the library.</p> <p>As a best practice, always specify an <code>Extension-Name</code> value for each library. If you do not specify an extension name, one is derived from the deployment name of the library. Default deployment names are different for archive and exploded archive deployments, and they can be set to arbitrary values in the deployment command.</p>
Specification-Version	<p>An optional String value that defines the specification version of the shared Java EE library. Referencing applications can optionally specify a required <code>Specification-Version</code> for a library; if the exact specification version is not available, deployment of the referencing application fails.</p> <p>The <code>Specification-Version</code> uses the following format:</p> <p>Major/minor version format, with version and revision numbers separated by periods (such as "9.0.1.1")</p> <p>Referencing applications can be configured to require either an exact version of the shared Java EE library, a minimum version, or the latest available version.</p> <p>The specification version for a shared Java EE library can also be set at the command-line when deploying the library, with some restrictions. See Section 12.7, "Deploying Shared Java EE Libraries and Dependent Applications".</p>
Implementation-Version	<p>An optional String value that defines the code implementation version of the shared Java EE library. You can provide an <code>Implementation-Version</code> only if you have also defined a <code>Specification-Version</code>.</p> <p><code>Implementation-Version</code> uses the following formats:</p> <ul style="list-style-type: none"> ■ Major/minor version format, with version and revision numbers separated by periods (such as "9.0.1.1") ■ Text format, with named versions (such as "9011Beta" or "9.0.1.1.B") <p>If you use the major/minor version format, referencing applications can be configured to require either an exact version of the shared Java EE library, a minimum version, or the latest available version. If you use the text format, referencing applications must specify the exact version of the library.</p> <p>The implementation version for a shared Java EE library can also be set at the command-line when deploying the library, with some restrictions. See Section 12.7, "Deploying Shared Java EE Libraries and Dependent Applications".</p>

To specify attributes in a manifest file:

1. Open (or create) the manifest file using a text editor. For the example shared Java EE library, you would use the commands:

```
cd /apps/myLibrary
mkdir META-INF
emacs META-INF/MANIFEST.MF
```

For the optional package example, use:

```
cd /apps/myOptPkg
mkdir META-INF
emacs META-INF/MANIFEST.MF
```

2. In the text editor, add a string value to specify the name of the shared Java EE library. For example:

```
Extension-Name: myExtension
```

Applications that reference the library must specify the exact `Extension-Name` in order to use the shared files.

3. As a best practice, enter the optional version information for the shared Java EE library. For example:

```
Extension-Name: myExtension
Specification-Version: 2.0
Implementation-Version: 9.0.0
```

Using the major/minor format for the version identifiers provides the most flexibility when referencing the library from another application (see [Table 12-2](#))

Note: Although you can optionally specify the `Specification-Version` and `Implementation-Version` at the command line during deployment, Oracle recommends that you include these strings in the `MANIFEST.MF` file. Including version strings in the manifest ensures that you can deploy new versions of the library alongside older versions. See [Section 12.7, "Deploying Shared Java EE Libraries and Dependent Applications"](#).

12.2.4 Packaging Shared Java EE Libraries for Distribution and Deployment

If you are delivering the shared Java EE Library or optional package for deployment by an administrator, package the deployment files into an archive file (an `.EAR` file or standalone module archive file for shared Java EE libraries, or a simple `.JAR` file for optional packages) for distribution. See [Section 6.1, "Deploying Applications Using `wldeploy`"](#).

Because a shared Java EE library is packaged as a standard Java EE application or standalone module, you may also choose to export a library's deployment configuration to a deployment plan, as described in *Deploying Applications to Oracle WebLogic Server*. Optional package `.JAR` files contain no deployment descriptors and cannot be exported.

For development purposes, you may choose to deploy libraries as exploded archive directories to facilitate repeated updates and redeployments.

12.3 Referencing Shared Java EE Libraries in an Enterprise Application

A Java EE application can reference a registered shared Java EE library using entries in the application's `weblogic-application.xml` deployment descriptor. [Table 12-2](#) describes the XML elements that define a library reference.

Table 12–2 *weblogic-application.xml* Elements for Referencing a Shared Java EE Library

Element	Description
library-ref	library-ref is the parent element in which you define a reference to a shared Java EE library. Enclose all other elements within library-ref.
library-name	A required string value that specifies the name of the shared Java EE library to use. library-name must exactly match the value of the Extension-Name attribute in the library's manifest file. (See Table 12–2 .)
specification-version	<p>An optional String value that defines the required specification version of the shared Java EE library. If this element is not set, the application uses a matching library with the highest specification version. If you specify a string value using major/minor version format, the application uses a matching library with the highest specification version that is not below the configured value. If all available libraries are below the configured specification-version, the application cannot be deployed. The required version can be further constrained by using the exact-match element, described below.</p> <p>If you specify a String value that does not use major/minor versioning conventions (for example, 9.2BETA) the application requires a shared Java EE library having the exact same string value in the Specification-Version attribute in the library's manifest file. (See Table 12–2.)</p>
implementation-version	<p>An optional String value that specifies the required implementation version of the shared Java EE library. If this element is not set, the application uses a matching library with the highest implementation version. If you specify a string value using major/minor version format, the application uses a matching library with the highest implementation version that is not below the configured value. If all available libraries are below the configured implementation-version, the application cannot be deployed. The required implementation version can be further constrained by using the exact-match element, described below.</p> <p>If you specify a String value that does not use major/minor versioning conventions (for example, 9.2BETA) the application requires a shared Java EE library having the exact same string value in the Implementation-Version attribute in the library's manifest file. (See Table 12–2.)</p>
exact-match	An optional Boolean value that determines whether the application should use a shared Java EE library with a higher specification or implementation version than the configured value, if one is available. By default this element is false, which means that WebLogic Server uses higher-versioned libraries if they are available. Set this element to true to require the exact matching version as specified in the specification-version and implementation-version elements.
context-root	<p>An optional String value that provides an alternate context root to use for a Web application shared Java EE library. Use this element if the context root of a library conflicts with the context root of a Web application in the referencing Java EE application.</p> <p><i>Web application shared Java EE library</i> refers to special kind of library: a Web application that is referenced by another Web application. See Section 12.8, "Web Application Shared Java EE Library Information".</p>

For example, this simple entry in the `weblogic-application.xml` descriptor references a shared Java EE library, `myLibrary`:

```
<library-ref>
  <library-name>myLibrary</library-name>
</library-ref>
```

In the above example, WebLogic Server attempts to find a library name `myLibrary` when deploying the dependent application. If more than one copy of `myLibrary` is registered, WebLogic Server selects the library with the highest specification version. If multiple copies of the library use the selected specification version, WebLogic Server selects the copy having the highest implementation version.

This example references a shared Java EE library with a requirement for the specification version:

```
<library-ref>
  <library-name>myLibrary</library-name>
  <specification-version>2.0</specification-version>
</library-ref>
```

In the above example, WebLogic Server looks for matching libraries having a specification version of 2.0 or higher. If multiple libraries are at or above version 2.0, WebLogic Server examines the selected libraries that use Float values for their implementation version and selects the one with the highest version. Note that WebLogic Server ignores any selected libraries that have a non-Float value for the implementation version.

This example references a shared Java EE library with both a specification version and a non-Float value implementation version:

```
<library-ref>
  <library-name>myLibrary</library-name>
  <specification-version>2.0</specification-version>
  <implementation-version>81Beta</implementation-version>
</library-ref>
```

In the above example, WebLogic Server searches for a library having a specification version of 2.0 or higher, and having an exact match of 81Beta for the implementation version.

The following example requires an exact match for both the specification and implementation versions:

```
<library-ref>
  <library-name>myLibrary</library-name>
  <specification-version>2.0</specification-version>
  <implementation-version>8.1</implementation-version>
  <exact-match>true</exact-match>
</library-ref>
```

The following example specifies a context-root with the library reference. When a WAR library reference is made from `weblogic-application.xml`, the context-root may be specified with the reference:

```
<library-ref>
  <library-name>myLibrary</library-name>
  <context-root>mywebapp</context-root>
</library-ref>
```

12.3.1 Overriding context-roots Within a Referenced Enterprise Library

A Java EE application can override context-roots within a referenced EAR library using entries in the application's `weblogic-application.xml` deployment descriptor. [Table 12-3](#) describes the XML elements that override context-root in a library reference.

Table 12–3 *weblogic-application.xml* Elements for Overriding a Shared Java EE Library

Element	Description
context-root	An optional String value that overrides the context-root elements declared in libraries. In the absence of this element, the library's context-root is used. Only a referencing application (for example, a user application) can override the context-root elements declared in its libraries.
override-value	An optional String value that specifies the value of the library-context-root-override element when overriding the context-root elements declared in libraries. In the absence of these elements, the library's context-root is used.

The following example specifies a context-root-override, which in turn, refers to the old context-root specified in one of its libraries and the new context-root that should be used instead. (override):

```
<library-ref>
  <library-name>myLibrary</library-name>
  <specification-version>2.0</specification-version>
  <implementation-version>8.1</implementation-version>
  <exact-match>true</exact-match>
</library-ref>
<library-context-root-override>
  <context-root>webapp</context-root>
  <override-value>mywebapp</override-value>
</library-context-root-override>
```

In the above example, the current application refers to myLibrary, which contains a Web application with a context-root of webapp. The only way to override this reference is to declare a library-context-root-override that maps webapp to mywebapp.

12.3.2 URIs for Shared Java EE Libraries Deployed As a Standalone Module

When referencing the URI of a shared Java EE library that was deployed as a standalone module (EJB or Web application), note that the module URI corresponds to the deployment name of the shared Java EE library. This can be a name that was manually assigned during deployment, the name of the archive file that was deployed, or the name of the exploded archive directory that was deployed. If you redeploy the same module using a different file name or from a different location, the default deployment name also changes and referencing applications must be updated to use the correct URI.

To avoid this problem, deploy all shared Java EE libraries as enterprise applications, rather than as standalone modules. If you choose to deploy a library as a standalone Java EE module, always specify a known deployment name and use that name as the URI in referencing applications.

12.4 Referencing Optional Packages from a Java EE Application or Module

Any Java EE archive (JAR, WAR, RAR, EAR) can reference one or more registered optional packages using attributes in the archive's manifest file.

Table 12–4 Manifest Attributes for Referencing Optional Packages

Attribute	Description
Extension-List <i>logical_name</i> [...]	<p>A required String value that defines a logical name for an optional package dependency. You can use multiple values in the <code>Extension-List</code> attribute to designate multiple optional package dependencies. For example:</p> <pre>Extension-List: dependency1 dependency2</pre>
[<i>logical_name</i> -]Extension-Name	<p>A required string value that identifies the name of an optional package dependency. This value must match the <code>Extension-Name</code> attribute defined in the optional package's manifest file.</p> <p>If you are referencing multiple optional packages from a single archive, prepend the appropriate logical name to the <code>Extension-Name</code> attribute. For example:</p> <pre>dependency1-Extension-Name: myOptPkg</pre>
[<i>logical_name</i> -]Specification-Version	<p>An optional String value that defines the required specification version of an optional package. If this element is not set, the archive uses a matching package with the highest specification version. If you include a <code>specification-version</code> value using the major/minor version format, the archive uses a matching package with the highest specification version that is not below the configured value. If all available package are below the configured <code>specification-version</code>, the archive cannot be deployed.</p> <p>If you specify a String value that does not use major/minor versioning conventions (for example, 9.2BETA) the archive requires a matching optional package having the exact same string value in the <code>Specification-Version</code> attribute in the package's manifest file. (See Table 12–2.)</p> <p>If you are referencing multiple optional packages from a single archive, prepend the appropriate logical name to the <code>Specification-Version</code> attribute.</p>
[<i>logical_name</i> -]Implementation-Version	<p>An optional String value that specifies the required implementation version of an optional package. If this element is not set, the archive uses a matching package with the highest implementation version. If you specify a string value using the major/minor version format, the archive uses a matching package with the highest implementation version that is not below the configured value. If all available libraries are below the configured <code>implementation-version</code>, the application cannot be deployed.</p> <p>If you specify a String value that does not use major/minor versioning conventions (for example, 9.2BETA) the archive requires a matching optional package having the exact same string value in the <code>Implementation-Version</code> attribute in the package's manifest file. (See Table 12–2.)</p> <p>If you are referencing multiple optional packages from a single archive, prepend the appropriate logical name to the <code>Implementation-Version</code> attribute.</p>

For example, this simple entry in the manifest file for a dependent archive references two optional packages, `myAppPkg` and `my3rdPartyPkg`:

```
Extension-List: internal 3rdparty
internal-Extension-Name: myAppPkg
3rdparty-Extension-Name: my3rdPartyPkg
```

This example requires a specification version of 2.0 or higher for `myAppPkg`:

```
Extension-List: internal 3rdparty
internal-Extension-Name: myAppPkg
3rdparty-Extension-Name: my3rdPartyPkg
internal-Specification-Version: 2.0
```

This example requires a specification version of 2.0 or higher for `myAppPkg`, and an exact match for the implementation version of `my3rdPartyPkg`:

```

Extension-List: internal 3rdparty
internal-Extension-Name: myAppPkg
3rdparty-Extension-Name: my3rdPartyPkg
internal-Specification-Version: 2.0
3rdparty-Implementation-Version: 8.1GA

```

By default, when WebLogic Server deploys an application or module and it cannot resolve a reference in the application's manifest file to an optional package, WebLogic Server prints a warning, but continues with the deployment anyway. You can change this behavior by setting the system property

`weblogic.application.RequireOptionalPackages` to `true` when you start WebLogic Server, either at the command line or in the command script file from which you start the server. Setting this system property to `true` means that WebLogic Server does *not* attempt to deploy an application or module if it cannot resolve an optional package reference in its manifest file.

12.5 Using weblogic.appmerge to Merge Libraries

`weblogic.appmerge` is a tool that is used to merge libraries into an application, with merged contents and merged descriptors. It also has the ability to write a merged application to disk. You can then use `weblogic.appmerge` to understand a library merge by examining the merged application you have written to disk.

- [Section 12.5.1, "Using weblogic.appmerge from the CLI"](#)
- [Section 12.5.2, "Using weblogic.appmerge as an Ant Task"](#)

12.5.1 Using weblogic.appmerge from the CLI

Invoke `weblogic.appmerge` using the following syntax:

```
java weblogic.appmerge [options] <ear, jar, war file, or directory>
```

where valid options are shown in [Table 12-5](#):

Table 12-5 *weblogic.appmerge Options*

Option	Comment
<code>-help</code>	Print the standard usage message.
<code>-version</code>	Print version information.
<code>-output <file></code>	Specifies an alternate output archive or directory. If not set, output is placed in the source archive or directory.
<code>-plan <file></code>	Specifies an optional deployment plan.
<code>-verbose</code>	Provide more verbose output.
<code>-library <file></code>	Comma-separated list of libraries. Each library may optionally set its name and versions, if not already set in its manifest, using the following syntax: <code><file> [@name=<string>@libspever=<version> @libimplver=<version string>].</code>
<code>-librarydir <dir></code>	Registers all files in specified directory as libraries.
<code>-writeInferredDescriptors</code>	Specifies that the application or module contains deployment descriptors with annotation information.

Example:

```
$ java weblogic.appmerge -output CompleteSportsApp.ear -library
Weather.war,Calendar.ear SportsApp.ear
```

12.5.2 Using `weblogic.appmerge` as an Ant Task

The ant task provides similar functionality as the command line utility. It supports `source`, `output`, `libraryDir`, `plan` and `verbose` attributes as well as multiple `<library>` sub-elements. Here is an example:

```
<taskdef name="appmerge" classname="weblogic.ant.taskdefs.j2ee.AppMergeTask" />
<appmerge source="SportsApp.ear" output="CompleteSportsApp.ear">
  <library file="Weather.war" />
  <library file="Calendar.ear" />
</appmerge>
```

12.6 Integrating Shared Java EE Libraries with the Split Development Directory Environment

The `BuildXMLGen` includes a `-librarydir` option to generate build targets that include one or more shared Java EE library directories. See [Section 4.5, "Generating a Basic build.xml File Using `weblogic.BuildXMLGen`"](#).

The `wlcompile` and `wlappc` Ant tasks include a `librarydir` attribute and `library` element to specify one or more shared Java EE library directories to include in the classpath for application builds. See [Section 5, "Building Applications in a Split Development Directory"](#).

12.7 Deploying Shared Java EE Libraries and Dependent Applications

Shared Java EE libraries are registered with one or more WebLogic Server instances by deploying them to the target servers and indicating that the deployments are to be shared. Shared Java EE libraries must be targeted to the same WebLogic Server instances you want to deploy applications that reference the libraries. If you try to deploy a referencing application to a server instance that has not registered a required library, deployment of the referencing application fails. See "Registering Libraries with WebLogic Server" in *Deploying Applications to Oracle WebLogic Server* for more information.

See "Install a Java EE Library" for detailed instructions on installing (deploying) a shared Java EE library using the WebLogic Server Administration Console. See "Target a Shared Java EE Library to a Server or Cluster" for instructions on using the WebLogic Server Administration Console to target the library to the server or cluster to which the application that is referencing the library is also targeted.

If you use the `wldeploy` Ant task as part of your iterative development process, use the `library`, `libImplVer`, and `libSpecVer` attributes to deploy a shared Java EE library. See [Appendix B, "wldeploy Ant Task Reference,"](#) for details and examples.

After registering a shared Java EE library, you can deploy applications and archives that depend on the library. Dependent applications can be deployed only if the target servers have registered all required libraries, and the registered deployments meet the version requirements of the application or archive. See "Deploying Applications that Reference Libraries" in *Deploying Applications to Oracle WebLogic Server* for more information.

12.8 Web Application Shared Java EE Library Information

In general, this topic discusses shared Java EE libraries that can be referenced only by enterprise applications. You can also create libraries that can be referenced only by

another Web application. The functionality is very similar to application libraries, although the method of referencing them is slightly different.

Note: For simplicity, this section uses the term *Web application library* when referring to a shared Java EE library that is referenced only by another Web application.

In particular:

- Web application libraries can only be referenced by other Web applications.
- Rather than update the `weblogic-application.xml` file, Web applications reference Web application libraries by updating the `weblogic.xml` deployment descriptor file. The elements are almost the same as those described in [Section 12.3, "Referencing Shared Java EE Libraries in an Enterprise Application"](#); the only difference is that the `<context-root>` child element of `<library-ref>` is ignored in this case.
- You cannot reference any other type of shared Java EE library (EJB, enterprise application, or plain JAR file) from the `weblogic.xml` deployment descriptor file of a Web application.

Other than these differences in how they are referenced, the way to create, package, and deploy a Web application library is the same as that of a standard shared Java EE library.

12.9 Using WebApp Libraries With Web Applications

Just as standard shared Java EE applications can be deployed to WebLogic Server as `application-libraries`, a standard Web application can be deployed to WebLogic Server as a `webapp-library` so that other Web applications can refer to these libraries.

Web application libraries facilitate the reuse of code and resources. Such libraries also help you separate out third-party Web applications or frameworks that your Web application might be using. Furthermore, common resources can be packaged separately as libraries and referenced in different Web applications, so that you don't have to bundle them with each Web application. When you include a `webapp-library` in your Web application, at deployment time the container merges all the static resources, classes, and JAR files into your Web application.

The first step in using a WebApp library is to register a Web application as a `webapp-library`. This can be accomplished by deploying a Web application using either the WebLogic Server Administration Console or the `weblogic.Deployer` tool as a library. To make other Web applications refer to this library, their `weblogic.xml` file must have a `library-ref` element pointing to the `webapp-library`, as follows:

```
<library-ref>
<library-name>BaseWebApp</library-name>
<specification-version>2.0</specification-version>
<implementation-version>8.1beta</implementation-version>
<exact-match>false</exact-match>
</library-ref>
```

When multiple libraries are present, the `CLASSPATH/resource` path precedence order follows the order in which the `library-refs` elements appear in the `weblogic.xml` file.

12.10 Accessing Registered Shared Java EE Library Information with LibraryRuntimeMBean

Each deployed shared Java EE library is represented by a `LibraryRuntimeMBean`. You can use this MBean to obtain information about the library itself, such as its name or version. You can also obtain the `ApplicationRuntimeMBeans` associated with deployed applications. `ApplicationRuntimeMBean` provides two methods to access the libraries that the application is using:

- `getLibraryRuntimes()` returns the shared Java EE libraries referenced in the `weblogic-application.xml` file.
- `getOptionalPackageRuntimes()` returns the optional packages referenced in the manifest file.

For more information, see the *Java API Reference for Oracle WebLogic Server*.

12.11 Order of Precedence of Modules When Referencing Shared Java EE Libraries

When an enterprise application references one or more shared Java EE libraries, and the application is deployed to WebLogic Server, the server internally merges the information in the `weblogic-application.xml` file of the referencing enterprise application with the information in the deployment descriptors of the referenced libraries. The order in which this happens is as follows:

1. When the enterprise application is deployed, WebLogic Server reads its `weblogic-application.xml` deployment descriptor.
2. WebLogic Server reads the deployment descriptors of any referenced shared Java EE libraries. Depending on the type of library (enterprise application, EJB, or Web application), the read file might be `weblogic-application.xml`, `weblogic.xml`, `weblogic-ejb-jar.xml`, and so on.
3. WebLogic Server first merges the referenced shared Java EE library deployment descriptors (in the order in which they are referenced, one at a time) and then merges the `weblogic-application.xml` file of the referencing enterprise application on top of the library descriptor files.

As a result of the way the descriptor files are merged, the elements in the descriptors of the shared Java EE libraries referenced first in the `weblogic-application.xml` file have precedence over the ones listed last. The elements of the enterprise application's descriptor itself have precedence over all elements in the library descriptors.

For example, assume that an enterprise application called `myApp` references two shared Java EE libraries (themselves packaged as enterprise applications): `myLibA` and `myLibB`, in that order. Both the `myApp` and `myLibA` applications include an EJB module called `myEJB`, and both the `myLibA` and `myLibB` applications include an EJB module called `myOtherEJB`.

Further assume that once the `myApp` application is deployed, a client invokes, via the `myApp` application, the `myEJB` module. In this case, WebLogic Server actually invokes the EJB in the `myApp` application (rather than the one in `myLibA`) because modules in the *referencing* application have higher precedence over modules in the *referenced* applications. If a client invokes the `myOtherEJB` EJB, then WebLogic Server invokes the one in `myLibA`, because the library is referenced first in the `weblogic-application.xml` file of `myApp`, and thus has precedence over the EJB with the same name in the `myLibB` application.

12.12 Best Practices for Using Shared Java EE Libraries

Keep in mind these best practices when developing shared Java EE libraries and optional packages:

- Use shared Java EE Libraries when you want to share one or more Java EE modules (EJBs, Web applications, enterprise applications, or plain Java classes) with multiple enterprise applications.
- If you need to deploy a standalone Java EE module, such as an EJB JAR file, as a shared Java EE library, package the module within an enterprise application. Doing so avoids potential URI conflicts, because the library URI of a standalone module is derived from the deployment name.
- If you choose to deploy a shared Java EE library as a standalone Java EE module, always specify a known deployment name during deployment and use that name as the URI in referencing applications.
- Use optional packages when multiple Java EE archive files need to share a set of Java classes.
- If you have a set of classes that must be available to applications in an entire domain, and you do not frequently update those classes (for example, if you need to share 3rd party classes in a domain), use the domain `/lib` subdirectory rather than using shared Java EE libraries or optional packages. Classes in the `/lib` subdirectory are made available (within a separate system level classloader) to all Java EE applications running on WebLogic Server instances in the domain.
- Always specify a specification version and implementation version, even if you do not intend to enforce version requirements with dependent applications. Specifying versions for shared Java EE libraries enables you to deploy multiple versions of the shared files for testing.
- Always specify an `Extension-Name` value for each shared Java EE library. If you do not specify an extension name, one is derived from the deployment name of the library. Default deployment names are different for archive and exploded archive deployments, and they can be set to arbitrary values in the deployment command.
- When developing a Web application for deployment as a shared Java EE library, use a unique context root. If the context root conflicts with the context root in a dependent Java EE application, use the `context-root` element in the EAR's `weblogic-application.xml` deployment descriptor to override the library's context root.
- Package shared Java EE libraries as archive files for delivery to administrators or deployers in your organization. Deploy libraries from exploded archive directories during development to allow for easy updates and repeated redeployments.
- Deploy shared Java EE libraries to all WebLogic Server instances on which you want to deploy dependent applications and archives. If a library is not registered with a server instance on which you want to deploy a referencing application, deployment of the referencing application fails.

Programming Application Life Cycle Events

This chapter describes how to create applications that respond to WebLogic Server application life cycle events.

This chapter includes the following sections:

- [Section 13.1, "Understanding Application Life Cycle Events"](#)
- [Section 13.2, "Registering Events in weblogic-application.xml"](#)
- [Section 13.3, "Programming Basic Life Cycle Listener Functionality"](#)
- [Section 13.4, "Examples of Configuring Life Cycle Events with and without the URI Parameter"](#)
- [Section 13.5, "Understanding Application Life Cycle Event Behavior During Re-deployment"](#)
- [Section 13.6, "Programming Application Version Life Cycle Events"](#)

Note: Application-scoped startup and shutdown classes have been deprecated as of release 9.0 of WebLogic Server. The information in this chapter about startup and shutdown classes is provided only for backwards compatibility. Instead, you should use life cycle listener events in your applications.

13.1 Understanding Application Life Cycle Events

Application life cycle listener events provide handles on which developers can control behavior during deployment, undeployment, and redeployment. This section discusses how you can use the application life cycle listener events.

Four application life cycle events are provided with WebLogic Server, which can be used to extend listener, shutdown, and startup classes. These include:

- Listeners—attachable to any event. Possible methods for Listeners are:

- `public void preStart(ApplicationLifecycleEvent evt) {}`

The `preStart` event is the beginning of the prepare phase, or the start of the application deployment process.

- `public void postStart(ApplicationLifecycleEvent evt) {}`

The `postStart` event is the end of the activate phase, or the end of the application deployment process. The application is deployed.

- `public void preStop(ApplicationLifecycleEvent evt) {}`

The preStop event is the beginning of the deactivate phase, or the start of the application removal or undeployment process.

- `public void postStop(ApplicationLifecycleEvent evt) {}`

The postStop event is the end of the remove phase, or the end of the application removal or undeployment process.

- Shutdown classes only get postStop events.

Note: Application-scoped shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Use life cycle listeners instead.

- Startup classes only get preStart events.

Notes: Application-scoped shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Use life cycle listeners instead.

For Startup and Shutdown classes, you only implement a `main{}` method. If you implement any of the methods provided for Listeners, they are ignored.

No `remove{}` method is provided in the `ApplicationLifecycleListener`, because the events are only fired at startup time during deployment (prestart and poststart) and shutdown during undeployment (prestop and poststop).

13.2 Registering Events in weblogic-application.xml

In order to use these events, you must register them in the `weblogic-application.xml` deployment descriptor. See [Appendix A, "Enterprise Application Deployment Descriptor Elements"](#). Define the following elements:

- `listener`—Used to register user defined application life cycle listeners. These are classes that extend the abstract base class `weblogic.application.ApplicationLifecycleListener`.
- `shutdown`—Used to register user-defined shutdown classes.
- `startup`—Used to register user-defined startup classes.

13.3 Programming Basic Life Cycle Listener Functionality

You create a listener by extending the abstract class (provided with WebLogic Server) `weblogic.application.ApplicationLifecycleListener`. The container then searches for your listener.

You override the following methods provided in the WebLogic Server `ApplicationLifecycleListener` abstract class to extend your application and add any required functionality:

- `preStart{}`
- `postStart{}`
- `preStop{}`
- `postStop{}`

[Example 13-1](#) illustrates how you override the `ApplicationLifecycleListener`. In this example, the public class `MyListener` extends `ApplicationLifecycleListener`.

Example 13-1 MyListener

```

import weblogic.application.ApplicationLifecycleListener;
import weblogic.application.ApplicationLifecycleEvent;
public class MyListener extends ApplicationLifecycleListener {
    public void preStart(ApplicationLifecycleEvent evt) {
        System.out.println
            ("MyListener(preStart) -- we should always see you..");
    } // preStart
    public void postStart(ApplicationLifecycleEvent evt) {
        System.out.println
            ("MyListener(postStart) -- we should always see you..");
    } // postStart
    public void preStop(ApplicationLifecycleEvent evt) {
        System.out.println
            ("MyListener(preStop) -- we should always see you..");
    } // preStop
    public void postStop(ApplicationLifecycleEvent evt) {
        System.out.println
            ("MyListener(postStop) -- we should always see you..");
    } // postStop
    public static void main(String[] args) {
        System.out.println
            ("MyListener(main): in main .. we should never see you..");
    } // main
}

```

[Example 13-2](#) illustrates how you implement the shutdown class. The shutdown class is attachable to preStop and postStop events. In this example, the public class MyShutdown does not extend ApplicationLifecycleListener because a shutdown class declared in the weblogic-application.xml deployment descriptor does not need to depend on any WebLogic Server-specific interfaces.

Example 13-2 MyShutdown

```

import weblogic.application.ApplicationLifecycleListener;
import weblogic.application.ApplicationLifecycleEvent;
public class MyShutdown {
    public static void main(String[] args) {
        System.out.println
            ("MyShutdown(main): in main .. should be for post-stop");
    } // main
}

```

[Example 13-3](#) illustrates how you implement the startup class. The startup class is attachable to preStart and postStart events. In this example, the public class MyStartup does not extend ApplicationLifecycleListener because a startup class declared in the weblogic-application.xml deployment descriptor does not need to depend on any WebLogic Server-specific interfaces.

Example 13-3 MyStartup

```

import weblogic.application.ApplicationLifecycleListener;
import weblogic.application.ApplicationLifecycleEvent;
public class MyStartup {
    public static void main(String[] args) {
        System.out.println
            ("MyStartup(main): in main .. should be for pre-start");
    } // main
}

```

13.3.1 Configuring a Role-Based Application Life Cycle Listener

You can configure an application life cycle event with role-based capability where a user identity can be specified to startup and shutdown events using the `run-as-principal-name` element. However, if the `run-as-principal-name` identity defined for the application life cycle listener is an administrator, the application deployer must have administrator privileges; otherwise, deployment will fail.

1. Follow the basic programming steps outlined in [Section 13.3, "Programming Basic Life Cycle Listener Functionality"](#).
2. Within the `listener` element add the `run-as-principal-name` element to specify the user who has privileges to startup and/or shutdown the event. For example:

```
<listener>
  <listener-class>myApp.MySessionAttributeListenerClass</listener-class>
  <run-as-principal-name>javajoe</run-as-principal-name>
</listener>
```

The identity specified here should be a valid user name in the system. If `run-as-principal-name` is not specified, the deployment initiator user identity will be used as the `run-as` identity for the execution of the application life cycle listener.

13.4 Examples of Configuring Life Cycle Events with and without the URI Parameter

The following examples illustrate how you configure application life cycle events in the `weblogic-application.xml` deployment descriptor file. The URI parameter is not required. You can place classes anywhere in the application `$CLASSPATH`. However, you must ensure that the class locations are defined in the `$CLASSPATH`. You can place listeners in `APP-INF/classes` or `APP-INF/lib`, if these directories are present in the EAR. In this case, they are automatically included in the `$CLASSPATH`.

The following example illustrates how you configure application life cycle events using the URI parameter. In this case, the archive `foo.jar` contains the classes and exists at the top level of the EAR file. For example: `myEar/foo.jar`.

Example 13–4 Configuring Application Life Cycle Events Using the URI Parameter

```
<listener>
  <listener-class>MyListener</listener-class>
  <listener-uri>foo.jar</listener-uri>
</listener>
<startup>
  <startup-class>MyStartup</startup-class>
  <startup-uri>foo.jar</startup-uri>
</startup>
<shutdown>
  <shutdown-class>MyShutdown</shutdown-class>
  <shutdown-uri>foo.jar</shutdown-uri>
</shutdown>
```

The following example illustrates how you configure application life cycle events without using the URI parameter.

Example 13–5 Configuring Application Life Cycle Events without Using the URI Parameter

```

<listener>
  <listener-class>MyListener</listener-class>
</listener>
<startup>
  <startup-class>MyStartup</startup-class>
</startup>
<shutdown>
  <shutdown-class>MyShutdown</shutdown-class>
</shutdown>

```

13.5 Understanding Application Life Cycle Event Behavior During Re-deployment

Application life cycle events are only triggered if a full re-deployment of the application occurs. During a full re-deployment of the application—provided the application life cycle events have been registered—the application life cycle first commences the shutdown sequence, next re-initializes its classes, and then performs the startup sequence.

For example, if your listener is registered for the full application life cycle set of events (preStart, postStart, preStop, postStop), during a full re-deployment, you see the following sequence of events:

1. preStop{}
2. postStop{}
3. Initialization takes place. (Unless you have set debug flags, you do not see the initialization.)
4. preStart{}
5. postStart{}

13.6 Programming Application Version Life Cycle Events

The following sections describe how to create applications that respond to WebLogic Server application version life cycle events:

- [Section 13.6.1, "Understanding Application Version Life Cycle Event Behavior"](#)
- [Section 13.6.2, "Types of Application Version Life Cycle Events"](#)
- [Section 13.6.3, "Example of Production Deployment Sequence When Using Application Version Life Cycle Events"](#)

13.6.1 Understanding Application Version Life Cycle Event Behavior

WebLogic Server provides application version life cycle event notifications by allowing you to extend the `ApplicationVersionLifecycleListener` class and specify a life cycle listener in `weblogic-application.xml`. See [Appendix A, "Enterprise Application Deployment Descriptor Elements"](#) and [Section 13.4, "Examples of Configuring Life Cycle Events with and without the URI Parameter"](#).

Application version life cycle events are invoked:

- For both static and dynamic deployments.

- Using either anonymous ID or using user identity.
- Only if the current application is versioned; otherwise, version life cycle events are ignored.
- For all application versions, including the version that registers the listener. Use the `ApplicationVersionLifecycleEvent.isOwnVersion` method to determine if an event belongs to a particular version. See the `ApplicationVersionLifecycleEvent` class for more information on types of version life cycle events.

13.6.2 Types of Application Version Life Cycle Events

Four application version life cycle events are provided with WebLogic Server:

- `public void preDeploy(ApplicationVersionLifecycleEvent evt)`
 - The `preDeploy` event is invoked when an application version deploy or redeploy operation is initiated.
- `public void postDeploy(ApplicationVersionLifecycleEvent evt)`
 - The `postDeploy` event is invoked when an application version is deployed or redeployed successfully.
- `public void preUndeploy(ApplicationVersionLifecycleEvent evt)`
 - The `preUndeploy` event is invoked when an application version undeploy operation is initiated.
- `public void postDelete(ApplicationVersionLifecycleEvent evt)`
 - The `postDelete` event is invoked when an application version is deleted.

Note: A `postDelete` event is only fired after the entire application version is completely removed. It does not include a partial undeploy, such as undeploying a module or from a subset of targets.

13.6.3 Example of Production Deployment Sequence When Using Application Version Life Cycle Events

The following table provides an example of a deployment (V1), production redeployment (V2), and an undeploy (V2).

Table 13–1 Sequence of Deployment Actions and Application Version Life Cycle Events

Deployment action	Time	Version V1	Version V2
Deployment of Version V1	T0	preDeploy(V1) invoked.	
	T1	Deployment starts.	
	T2	Application life cycle listeners for V1 are registered.	
	T3	V1 is active version, Deployment is complete.	
	T4	postDeploy(V1) invoked.	
	T5	Application Listeners gets postDeploy(V1).	

Table 13–1 (Cont.) Sequence of Deployment Actions and Application Version Life Cycle Events

Deployment action	Time	Version V1	Version V2	
Production Redeployment of Version V2	T6		preDeploy(V2) invoked.	
	T7	Application version listener receives preDeploy(V1).		
	T8		Deployment starts.	
	T9		Application life cycle listeners for V2 are registered.	
	T10	If deploy(V2) succeeds, V1 ceases to be active version.	If deploy(V2) succeeds, V2 replaces V1 as active version. Deployment is complete.	
	T11		postDeploy(V2) invoked. Note: This event occurs even if the deployment fails.	
	T12	Application version listener gets postDeploy(V2). If deploy(V2) fails, V1 remains active.		
	T13		Application listeners gets postDeploy(V2).	
	T14	If deploy(V2) succeeds, V1 begins retirement.		
	T15	Application listeners for V1 are unregistered.		
	T16	V1 is retired.		
	Undeployment of V2	T17		preUndeploy(v2) invoked.
		T18		Application listeners gets preUndeploy(v2) invoked.
		T19		Undeployment begins.
		T20		V2 is no longer active version.
		T21		Application version listeners for V2 are unregistered.
T22			Undeployment is complete.	
T23			If the entire application is undeployed, postDelete(V2) is invoked. Note: This event occurs even if the undeployment fails.	

Programming Context Propagation

This chapter describes how to use the context propagation APIs in your applications.

This chapter includes the following sections:

- [Section 14.1, "Understanding Context Propagation"](#)
- [Section 14.2, "Programming Context Propagation: Main Steps"](#)
- [Section 14.3, "Programming Context Propagation in a Client"](#)
- [Section 14.4, "Programming Context Propagation in an Application"](#)

14.1 Understanding Context Propagation

Context propagation allows programmers to associate information with an application which is then carried along with every request. Furthermore, downstream components can add or modify this information so that it can be carried back to the originator. Context propagation attaches information to a request through a `WorkContext`. This information follows the request to any process that supports context propagation through a `PropagationMode`. Context propagation is also known as *work areas*, *work contexts*, or *application transactions*.

Common use-cases for context propagation are any type of application in which information, usually related to the request, needs to be carried outside the application or to another application, rather than the information being an integral part of the application. Examples of these use cases include diagnostics monitoring, application transactions, and application load-balancing. The ability of context propagation to tie information to a request greatly simplifies managing such data, in contrast to maintaining a map of request data in each application and then implementing custom code to transmit such information between applications or threads.

However, context propagation can occur within an application. For example, if an application submits work through a `Work Manager`, part of the processing occurs in different threads. Context propagation uses a `PropagationMode` to carry information to other threads.

Programming context propagation has two parts: first you code the client application to create a `WorkContextMap` and `WorkContext`, and then add user data to the context, and then you code the invoked application itself to get and possibly use this data. The invoked application can be of any type: EJB, Web service, servlet, JMS topic or queue, and so on. See [Section 14.2, "Programming Context Propagation: Main Steps"](#) for details.

The `WebLogic` context propagation APIs are in the `weblogic.workarea` package. The following table describes the main interfaces and classes.

Table 14–1 Interfaces and classes of the WebLogic Context Propagation API

Interface or Class	Description
WorkContextMap Interface	Main context propagation interface used to tag applications with data and propagate that information via application requests. <i>WorkContextMaps</i> is part of the client or application's JNDI environment and can be accessed through JNDI by looking up the name <code>java:comp/WorkContextMap</code> .
WorkContext Interface	Interface used for marshaling and unmarshaling the user data that is passed along with an application. This interface has four implementing classes for marshaling and unmarshaling the following types of data: simple 8-bit ASCII contexts (<i>AsciiWorkContext</i>), long contexts (<i>LongWorkContext</i>), Serializable context (<i>SerializableWorkContext</i>), and String contexts (<i>StringWorkContext</i>). <i>WorkContext</i> has one subinterface, <i>PrimitiveWorkContext</i> , used to specifically marshal and unmarshal a single primitive data item.
WorkContextOutput/Input Interfaces	Interfaces representing primitive streams used for marshaling and unmarshaling, respectively, <i>WorkContext</i> implementations.
PropagationMode Interface	Defines the propagation properties of <i>WorkContexts</i> . Specifies whether the <i>WorkContext</i> is propagated locally, across threads, across RMI invocations, across JMS queues and topics, or across SOAP messages. If not specified, default is to propagate data across remote and local calls in the same thread.
PrimitiveContextFactory Class	Convenience class for creating <i>WorkContexts</i> that contain only primitive data.

For the complete API documentation about context propagation, see the `weblogic.workarea` Javadocs.

14.2 Programming Context Propagation: Main Steps

The following procedure describes the high-level steps to use context propagation with WebLogic Server. This example demonstrates how to associate information to a request on a client, how to retrieve that information on the server, and then how to retrieve the value updated by the server instance. It is assumed in the procedure that you have already set up your iterative development environment and have an existing client and application that you want to update to use context propagation by using the `weblogic.workarea` API.

1. Update your client application to create the *WorkContextMap* and *WorkContext* objects and then add user data to the context.
See [Section 14.3, "Programming Context Propagation in a Client"](#).
2. If your client application is standalone (rather than running in a Java EE component deployed to WebLogic Server), ensure that its CLASSPATH includes the Java EE application client, also called the *thin client*.
See *Developing Stand-alone Clients for Oracle WebLogic Server*.
3. Update your application (EJB, Web service, servlet, and so on) to also create a *WorkContextMap* and then get the context and user data that you added from the client application.
See [Section 14.4, "Programming Context Propagation in an Application"](#).

14.3 Programming Context Propagation in a Client

The following sample Java code shows a standalone Java client that invokes a Web service; the example also shows how to use the `weblogic.workarea.* context`

propagation APIs to associate user information with the invoke. The code relevant to context propagation is shown in bold and explained after the example.

For the complete API documentation about context propagation, see the `weblogic.workarea` Javadocs.

Note: See *Developing JAX-WS Web Services for Oracle WebLogic Server* for information on creating Web services and client applications that invoke them.

```
package examples.workarea.client;
import java.rmi.RemoteException;
import javax.xml.rpc.ServiceException;
import javax.xml.rpc.Stub;
import javax.naming.InitialContext;
import javax.naming.NamingException;
import weblogic.workarea.WorkContextMap;
import weblogic.workarea.WorkContext;
import weblogic.workarea.PrimitiveContextFactory;
import weblogic.workarea.PropagationMode;
import weblogic.workarea.PropertyReadOnlyException;
/**
 * This is a simple standalone client application that invokes the
 * the <code>sayHello</code> operation of your WorkArea Web service.
 *
 */
public class Main {
    public final static String SESSION_ID= "session_id_key";
    public static void main(String[] args)
        throws ServiceException, RemoteException, NamingException,
        PropertyReadOnlyException{
        YourWorkAreaService service = new YourWorkAreaService(args[0] + "?WSDL");
        YourWorkAreaPortType port = service.getWorkAreaPort();
        WorkContextMap map = (WorkContextMap)new
InitialContext().lookup("java:comp/WorkContextMap");
        WorkContext stringContext = PrimitiveContextFactory.create("A String
Context");
        // Put a string context
        map.put(SESSION_ID, stringContext, PropagationMode.SOAP);
        try {
            String result = null;
            result = port.sayHello("Hi there!");
            System.out.println( "Got result: " + result );
        } catch (RemoteException e) {
            throw e;
        }
    }
}
```

In the preceding example:

- The following code shows how to import the needed `weblogic.workarea.*` classes, interfaces, and exceptions:

```
import weblogic.workarea.WorkContextMap;
import weblogic.workarea.WorkContext;
import weblogic.workarea.PrimitiveContextFactory;
import weblogic.workarea.PropagationMode;
import weblogic.workarea.PropertyReadOnlyException;
```

- Substitute your implementation of the `WorkArea` service and port for your Web service for `YourWorkAreaService` and `YourWorkAreaPortType`.

- The following code shows how to create a `WorkContextMap` by doing a JNDI lookup of the context propagation-specific JNDI name

```
java:comp/WorkContextMap:

WorkContextMap map = (WorkContextMap)
    new InitialContext().lookup("java:comp/WorkContextMap");
```

- The following code shows how to create a `WorkContext` by using the `PrimitiveContextFactory`. In this example, the `WorkContext` consists of the simple `String` value `A String Context`. This `String` value is the user data that is passed to the invoked Web service.

```
WorkContext stringContext =
    PrimitiveContextFactory.create("A String Context");
```

- The following code saves the `stringContext` under the `SESSION_ID` key in the `WorkContextMap`. Specifying the propagation mode of `SOAP` causes the propagation of the `stringContext` along any `SOAP` message sent to servers supporting context propagation.

```
map.put(SESSION_ID, stringContext, PropagationMode.SOAP);
```

14.4 Programming Context Propagation in an Application

The following sample Java code shows a simple Java Web service (JWS) file that implements a Web service. The JWS file also includes context propagation code to get the user data that is associated with the invoke of the Web service. The code relevant to context propagation is shown in bold and explained after the example.

For the complete API documentation about context propagation, see the `weblogic.workarea` Javadocs.

Note: See *Developing JAX-WS Web Services for Oracle WebLogic Server* for information on creating Web services and client applications that invoke them.

```
package examples.workarea;
import javax.naming.InitialContext;
// Import the Context Propagation classes
import weblogic.workarea.WorkContextMap;
import weblogic.workarea.WorkContext;
import javax.jws.WebMethod;
import javax.jws.WebService;
import weblogic.jws.WLHttpTransport;
@WebService(name="WorkAreaPortType",
            serviceName="WorkAreaService",
            targetNamespace="http://example.org")
@WLHttpTransport(contextPath="workarea",
                 serviceUri="WorkAreaService",
                 portName="WorkAreaPort")
/**
 * This JWS file forms the basis of simple WebLogic
 * Web service with a single operation: sayHello
 *
 */
```

```

public class WorkContextAwareWebService {
    public final static String SESSION_ID = "session_id_key";
    @WebMethod()
    public String sayHello(String message) {
        try {
            WorkContextMap map = (WorkContextMap) new
InitialContext().lookup("java:comp/WorkContextMap");
            WorkContext modifiedLocalWC = PrimitiveContextFactory.create(localwc.get() + "
could be replaced by a new value...");
            map.put(SESSION_ID, newLocalWC, PropagationMode.SOAP);
            System.out.println("local context: " + localwc);
            System.out.println("sayHello: " + message);
            return "The server received message: " + message + ", with SESSION_ID: " +
localwc;
        } catch (Throwable t) {
            return "error";
        }
    }
}

```

In the preceding example:

- The following code shows how to import the needed context propagation APIs; in this case, only the `WorkContextMap` and `WorkContext` interfaces are needed:

```

import weblogic.workarea.WorkContextMap;
import weblogic.workarea.WorkContext;

```

- The following code shows how to create a `WorkContextMap` by doing a JNDI lookup of the context propagation-specific JNDI name `java:comp/WorkContextMap`:

```

WorkContextMap map = (WorkContextMap)
    new InitialContext().lookup("java:comp/WorkContextMap");

```

- The propagation mode is `SOAP` only, meaning that propagation occurs both to the server with the request and to the client with the response. The following code shows how the server instance could modify the `stringContext`:

```

WorkContext modifiedLocalWC = PrimitiveContextFactory.create(localwc.get() + "
could be replaced by a new value...");

```

- The following code replaces the work context with an updated value. When retrieving `SESSION_ID` on the client after the server returns the response, the value updated by the server is now present on the client.

```

map.put(SESSION_ID, newLocalWC, PropagationMode.SOAP);

```

Programming JavaMail with WebLogic Server

This chapter describes how to program JavaMail with WebLogic Server to add email capabilities to your WebLogic Server applications.

This chapter includes the following sections:

- [Section 15.1, "Overview of Using JavaMail with WebLogic Server Applications"](#)
- [Section 15.2, "Understanding JavaMail Configuration Files"](#)
- [Section 15.3, "Configuring JavaMail for WebLogic Server"](#)
- [Section 15.4, "Sending Messages with JavaMail"](#)
- [Section 15.5, "Reading Messages with JavaMail"](#)

15.1 Overview of Using JavaMail with WebLogic Server Applications

WebLogic Server includes the JavaMail API version 1.4 reference implementation. Using the JavaMail API, you can add email capabilities to your WebLogic Server applications. JavaMail provides access from Java applications to Internet Message Access Protocol (IMAP)- and Simple Mail Transfer Protocol (SMTP)-capable mail servers on your network or the Internet. It does not provide mail server functionality; you must have access to a mail server to use JavaMail.

Complete documentation for using the JavaMail API is available at <http://www.oracle.com/technetwork/java/javamail-138606.html>. This section describes how you can use JavaMail in the WebLogic Server environment.

The `weblogic.jar` file contains the following JavaMail API packages:

- `javax.mail`
- `javax.mail.event`
- `javax.mail.internet`
- `javax.mail.search`

The `weblogic.jar` also contains the Java Activation Framework (JAF) package, which JavaMail requires.

The `javax.mail` package includes providers for Internet Message Access protocol (IMAP) and Simple Mail Transfer Protocol (SMTP) mail servers. There is a separate POP3 provider for JavaMail, which is not included in `weblogic.jar`. You can download the POP3 provider at <http://www.oracle.com/technetwork/java/javamail/index-138643.html> and add it to the WebLogic Server classpath if you want to use it.

15.2 Understanding JavaMail Configuration Files

JavaMail depends on configuration files that define the mail transport capabilities of the system. The `weblogic.jar` file contains the standard configuration files which enable IMAP and SMTP mail servers for JavaMail and define the default message types JavaMail can process.

Unless you want to extend JavaMail to support additional transports, protocols, and message types, you do not have to modify any JavaMail configuration files. If you do want to extend JavaMail, see

<http://www.oracle.com/technetwork/java/javamail-138606.html>. Then add your extended JavaMail package in the WebLogic Server classpath *in front of* `weblogic.jar`.

15.3 Configuring JavaMail for WebLogic Server

To configure JavaMail for use in WebLogic Server, you create a mail session in the WebLogic Server Administration Console. This allows server-side modules and applications to access JavaMail services with JNDI, using Session properties you preconfigure for them. For example, by creating a mail session, you can designate the mail hosts, transport and store protocols, and the default mail user in the WebLogic Server Administration Console so that modules that use JavaMail do not have to set these properties. Applications that are heavy email users benefit because the mail session creates a single `javax.mail.Session` object and makes it available via JNDI to any module that needs it.

For information on using the WebLogic Server Administration Console to create a mail session, see "Configure access to JavaMail" in the *Oracle WebLogic Server Administration Console Online Help*.

You can override any properties set in the mail session in your code by creating a `java.util.Properties` object containing the properties you want to override. See [Section 15.4, "Sending Messages with JavaMail"](#). Then, after you look up the mail session object in JNDI, call the `Session.getInstance()` method with your `Properties` object to get a customized Session.

15.4 Sending Messages with JavaMail

Here are the steps to send a message with JavaMail from within a WebLogic Server module:

1. Import the JNDI (naming), JavaBean Activation, and JavaMail packages. You will also need to import `java.util.Properties`:

```
import java.util.*;
import javax.activation.*;
import javax.mail.*;
import javax.mail.internet.*;
import javax.naming.*;
```

2. Look up the Mail Session in JNDI:

```
InitialContext ic = new InitialContext();
Session session = (Session) ic.lookup("myMailSession");
```

3. If you need to override the properties you set for the Session in the WebLogic Server Administration Console, create a `java.util.Properties` object and add the properties you want to override. Then call `getInstance()` to get a new Session object with the new properties.

```

Properties props = new Properties();
props.put("mail.transport.protocol", "smtp");
props.put("mail.smtp.host", "mailhost");
// use mail address from HTML form for from address
props.put("mail.from", emailAddress);
Session session2 = session.getInstance(props);

```

4. Construct a `MimeMessage`. In the following example, *to*, *subject*, and *messageTxt* are `String` variables containing input from the user.

```

Message msg = new MimeMessage(session2);
msg.setFrom();
msg.setRecipients(Message.RecipientType.TO,
    InternetAddress.parse(to, false));
msg.setSubject(subject);
msg.setSentDate(new Date());
// Content is stored in a MIME multi-part message
// with one body part
MimeBodyPart mbp = new MimeBodyPart();
mbp.setText(messageTxt);
Multipart mp = new MimeMultipart();
mp.addBodyPart(mbp);
msg.setContent(mp);

```

5. Send the message.

```
Transport.send(msg);
```

The JNDI lookup can throw a `NamingException` on failure. JavaMail can throw a `MessagingException` if there are problems locating transport classes or if communications with the mail host fails. Be sure to put your code in a try block and catch these exceptions.

15.5 Reading Messages with JavaMail

The JavaMail API allows you to connect to a message store, which could be an IMAP server or POP3 server. Messages are stored in folders. With IMAP, message folders are stored on the mail server, including folders that contain incoming messages and folders that contain archived messages. With POP3, the server provides a folder that stores messages as they arrive. When a client connects to a POP3 server, it retrieves the messages and transfers them to a message store on the client.

Folders are hierarchical structures, similar to disk directories. A folder can contain messages or other folders. The default folder is at the top of the structure. The special folder name INBOX refers to the primary folder for the user, and is within the default folder. To read incoming mail, you get the default folder from the store, and then get the INBOX folder from the default folder.

The API provides several options for reading messages, such as reading a specified message number or range of message numbers, or pre-fetching specific parts of messages into the folder's cache. See the JavaMail API for more information.

Here are steps to read incoming messages on a POP3 server from within a WebLogic Server module:

1. Import the JNDI (naming), JavaBean Activation, and JavaMail packages. You will also need to import `java.util.Properties`:

```

import java.util.*;
import javax.activation.*;
import javax.mail.*;

```

```
import javax.mail.internet.*;
import javax.naming.*;
```

2. Look up the Mail Session in JNDI:

```
InitialContext ic = new InitialContext();
Session session = (Session) ic.lookup("myMailSession");
```

3. If you need to override the properties you set for the Session in the WebLogic Server Administration Console, create a Properties object and add the properties you want to override. Then call getInstance() to get a new Session object with the new properties:

```
Properties props = new Properties();
props.put("mail.store.protocol", "pop3");
props.put("mail.pop3.host", "mailhost");
Session session2 = session.getInstance(props);
```

4. Get a Store object from the Session and call its connect() method to connect to the mail server. To authenticate the connection, you need to supply the mailhost, user name, and password in the connect method:

```
Store store = session.getStore();
store.connect(mailhost, username, password);
```

5. Get the default folder, then use it to get the INBOX folder:

```
Folder folder = store.getDefaultFolder();
folder = folder.getFolder("INBOX");
```

6. Read the messages in the folder into an array of Messages:

```
Message[] messages = folder.getMessages();
```

7. Operate on messages in the Message array. The Message class has methods that allow you to access the different parts of a message, including headers, flags, and message contents.

Reading messages from an IMAP server is similar to reading messages from a POP3 server. With IMAP, however, the JavaMail API provides methods to create and manipulate folders and transfer messages between them. If you use an IMAP server, you can implement a full-featured, Web-based mail client with much less code than if you use a POP3 server. With POP3, you must provide code to manage a message store via WebLogic Server, possibly using a database or file system to represent folders.

Threading and Clustering Topics

This chapter describes how to use threads in WebLogic Server as well as how to program applications for use in WebLogic Server clusters.

This chapter includes the following sections:

- [Section 16.1, "Using Threads in WebLogic Server"](#)
- [Section 16.2, "Using the Work Manager API for Lower-Level Threading"](#)
- [Section 16.3, "Programming Applications for WebLogic Server Clusters"](#)

16.1 Using Threads in WebLogic Server

WebLogic Server is a sophisticated, multi-threaded application server and it carefully manages resource allocation, concurrency, and thread synchronization for the modules it hosts. To obtain the greatest advantage from WebLogic Server's architecture, construct your application modules created according to the standard Java EE APIs.

In most cases, avoid application designs that require creating new threads in server-side modules:

- Applications that create their own threads do not scale well. Threads in the JVM are a limited resource that must be allocated thoughtfully. Your applications may break or cause WebLogic Server to thrash when the server load increases. Problems such as deadlocks and thread starvation may not appear until the application is under a heavy load.
- Multithreaded modules are complex and difficult to debug. Interactions between application-generated threads and WebLogic Server threads are especially difficult to anticipate and analyze.

In some situations, creating threads may be appropriate, in spite of these warnings. For example, an application that searches several repositories and returns a combined result set can return results sooner if the searches are done asynchronously using a new thread for each repository instead of synchronously using the main client thread.

If you must use threads in your application code, create a pool of threads so that you can control the number of threads your application creates. Like a JDBC connection pool, you allocate a given number of threads to a pool, and then obtain an available thread from the pool for your runnable class. If all threads in the pool are in use, wait until one is returned. A thread pool helps avoid performance issues and allows you to optimize the allocation of threads between WebLogic Server execution threads and your application.

Be sure you understand where your threads can deadlock and handle the deadlocks when they occur. Review your design carefully to ensure that your threads do not compromise the security system.

To avoid undesirable interactions with WebLogic Server threads, do not let your threads call into WebLogic Server modules. For example, do not use enterprise beans or servlets from threads that you create. Application threads are best used for independent, isolated tasks, such as conversing with an external service with a TCP/IP connection or, with proper locking, reading or writing to files. A short-lived thread that accomplishes a single purpose and ends (or returns to the thread pool) is less likely to interfere with other threads.

Avoid creating daemon threads in modules that are packaged in applications deployed on WebLogic Server. When you create a daemon thread in an application module such as a servlet, you will not be able to redeploy the application because the daemon thread created in the original deployment will remain running.

Be sure to test multithreaded code under increasingly heavy loads, adding clients even to the point of failure. Observe the application performance and WebLogic Server behavior and then add checks to prevent failures from occurring in production.

16.2 Using the Work Manager API for Lower-Level Threading

The Work Manager provides a simple API for concurrent execution of work items. This enables Java EE-based applications (including servlets and EJBs) to schedule work items for concurrent execution, which will provide greater throughput and increased response time. After an application submits work items to a Work Manager for concurrent execution, the application can gather the results. The Work Manager provides common "join" operations, such as waiting for any or all work items to complete. The Work Manager for Application Servers specification provides an application-server-supported alternative to using lower-level threading APIs, which are inappropriate for use in managed environments such as servlets and EJBs, as well as being too difficult to use for most applications.

For more information, see "Using Work Managers to Optimize Scheduled Work".

16.3 Programming Applications for WebLogic Server Clusters

JSPs and servlets that will be deployed to a WebLogic Server cluster must observe certain requirements for preserving session data. See "Requirements for HTTP Session State Replication" in *Administering Clusters for Oracle WebLogic Server* for more information.

EJBs deployed in a WebLogic Server cluster have certain restrictions based on EJB type. See "Understanding WebLogic Enterprise JavaBeans" in *Developing Enterprise JavaBeans, Version 2.1, for Oracle WebLogic Server* for information about the capabilities of different EJB types in a cluster. EJBs can be deployed to a cluster by setting clustering properties in the EJB deployment descriptor.

If you are developing either EJBs or custom RMI objects for deployment in a cluster, also refer to "Using WebLogic JNDI in a Clustered Environment" in *Developing JNDI Applications for Oracle WebLogic Server* to understand the implications of binding clustered objects in the JNDI tree.

Developing OSGi Bundles for WebLogic Server Applications

This chapter describes the OSGi environment in WebLogic Server and how to deploy OSGi bundles to WebLogic Server. Developers who want to use OSGi in their applications can easily share OSGi facilities, such as the OSGi service registry, class loaders, and other OSGi services.

For general information about OSGi, see <http://www.osgi.org>.

This chapter includes the following sections:

- [Section 17.1, "Understanding OSGi"](#)
- [Section 17.2, "Features Provided in WebLogic Server OSGi Implementation"](#)
- [Section 17.3, "Configuring the OSGi Framework"](#)
- [Section 17.4, "Creating OSGi Bundles"](#)
- [Section 17.5, "Deploying OSGi Bundles"](#)
- [Section 17.6, "Accessing Deployed Bundle Objects From JNDI"](#)
- [Section 17.7, "Using OSGi Logging Via WebLogic Server"](#)
- [Section 17.8, "Configuring a Filtering ClassLoader for OSGi Bundles"](#)
- [Section 17.9, "OSGi Example"](#)

17.1 Understanding OSGi

OSGi is a Java modularity system developed and maintained by the OSGi Alliance, of which Oracle is a member.

The OSGi specifications and related Javadoc together describe a comprehensive operating environment for Java applications:

- You can download the OSGi Service Platform Core Specification from <http://www.osgi.org/Release4/Download>.
- The OSGi Javadoc is available from <http://www.osgi.org/Release4/Javadoc>.

As described on the OSGi Alliance Technology Web page (<http://www.osgi.org/About/Technology>), "OSGi technology is the dynamic module system for Java. The OSGi Service Platform provides functionality to Java that makes Java the premier environment for software integration and thus for development. Java provides the portability that is required to support products on many different platforms. The OSGi technology provides the standardized primitives that allow

applications to be constructed from small, reusable and collaborative components. These components can be composed into an application and deployed."

The OSGi Architecture Web page <http://www.osgi.org/About/WhatIsOSGi> further describes the OSGi technology as "...a set of specifications that define a dynamic component system for Java. These specifications enable a development model where applications are (dynamically) composed of many different (reusable) components. The OSGi specifications enable components to hide their implementations from other components while communicating through services, which are objects that are specifically shared between components. This surprisingly simple model has far reaching effects for almost any aspect of the software development process."

OSGi offers you the following benefits, as described in Benefits of Using OSGi <http://www.osgi.org/About/WhyOSGi>:

- Versioning of package wiring, for both implementors and users of interfaces.
- The "uses" directive allows for intelligent wiring of class loaders and helps ensure a consistent class space.
- Flexible and dynamic security.
- Dynamic service wiring through an active registry.
- Various standard OSGi specifications provided by multiple vendors.

17.2 Features Provided in WebLogic Server OSGi Implementation

WebLogic Server allows you to add a list of OSGi frameworks (maintained via `OsgiFrameWorkMBean` MBeans) to the server configuration. After the OSGi framework has been booted, a bundle object for the framework is placed into the local server JNDI tree. Applications can then get this bundle from JNDI and thereafter use that as their entry point into the OSGi system.

Applications can also deploy their own OSGi bundles. One specific OSGi bundle from the chosen framework instance can be used in the application classloader hierarchy.

WebLogic Server allows you to:

- Configure and manage one or more instances of an OSGi framework from the Weblogic Server Administration Console and WLST.

WebLogic Server includes the Apache Felix implementation of the OSGi framework. See <http://felix.apache.org> for information on Felix.

- Create and deploy your own OSGi bundles.

WebLogic Server includes an OSGi bundle containing the OSGi API. You can use this API to create your own OSGi bundles.

- One specific OSGi bundle from the chosen framework instance can be used in the application classloader hierarchy.
- Access OSGi bundles directly from JNDI.
- Deploy and undeploy OSGi bundles.
- Log OSGi status via the WebLogic Server logging mechanism.
- Incorporate the OSGi services of your choice.
- Enable OSGi persistence.
- Manage OSGi bundle start levels for deployed bundles.

These topics are described in the sections that follow.

17.3 Configuring the OSGi Framework

As described in the OSGi Service Platform Core Specification, "The Framework forms the core of the OSGi Service Platform Specifications. It provides a general-purpose, secure, and managed Java framework that supports the deployment of extensible and downloadable applications known as bundles."

WebLogic Server includes the Felix implementation of OSGi framework. You can configure and manage one or more instances of the Felix OSGi framework.

Note: WebLogic Server supports only the Felix framework. Other OSGi Frameworks are not supported and have not been tested.

This section includes the following subsections:

- [Section 17.3.1, "Configuring OSGi Framework Instances"](#)
- [Section 17.3.2, "Configuring OSGi Framework Persistence"](#)

17.3.1 Configuring OSGi Framework Instances

WebLogic Server includes an OSGi framework by default, but it does not automatically start it.

You must configure WebLogic Server to boot an OSGi framework when WebLogic Server boots. You can do this in four ways, according to your preference:

- Use the WebLogic Server Administration Console to configure an OSGi framework instance.
- Edit the `DOMAIN_HOME\config\config.xml` deployment descriptor file to add an entry for the OSGi server and set the attribute values. You specify the OSGi framework you want the WebLogic Server instance to use.
- Use WLST to create the OSGi framework and set the attribute values. WLST then stores the values in the `DOMAIN_HOME\config\config.xml` deployment descriptor file.
- Write a Java program to create the OSGi framework and set the attribute values.

In all four cases, configuration of an OSGi framework instance is controlled by the `OsgiFrameWorkMBean`. For each framework associated with an `OsgiFrameWorkMBean`, WebLogic Server boots an OSGi framework with a unique name.

You configure the OSGi framework attributes shown in [Table 17-1](#).

Table 17-1 OSGi Framework Attributes

Attribute	Usage
Target	This attribute is required. You must select a target (servers or clusters) on which an MBean will be deployed from the list of servers or clusters in the current domain on which this item can be deployed.
Name	The name of the framework instance. The name of a given framework instance must be unique within a WebLogic Server server instance.

Table 17–1 (Cont.) OSGi Framework Attributes

Attribute	Usage
Implementation Class	The name of the framework implementation class for the <code>org.osgi.framework.launch.FrameworkFactory</code> class. The default value is <code>org.apache.felix.framework.FrameworkFactory</code> .
Deploy Installation Bundles	Determines whether OSGi bundles are installed in the framework. This attribute is "populate" by default. See Section 17.3.1.5, "Parameter Required for Installing Bundles in the Framework" for more information.
Dynamically Created	Determines whether the MBean is created dynamically or is persisted to <code>config.xml</code> . The configuration is always persisted if you use the WebLogic Server Administration Console and this attribute is not displayed.
Init Properties	The standard Felix properties to be used when initializing the framework. All standard properties and all properties specific to the framework can be set. See Example 17–3 for an example of setting the Init Properties from a Java program. The Apache Felix Framework Configuration Properties are described in http://felix.apache.org/documentation/subprojects/apache-felix-framework/apache-felix-framework-configuration-properties.html .
Framework Boot delegation	The name of the <code>org.osgi.framework.bootdelegation</code> property. Note that this value, if set, will take precedence over anything specified in the <code>init-properties</code> .
Framework System Packages Extra	The name of the <code>org.osgi.framework.system.packages.extra</code> property. Note that this value, if set, will take precedence over anything specified in the <code>init-properties</code> .
Register Global Data Sources	Boolean. Returns true if global data sources should be added to the OSGi service registry.
Register Global Work Managers	Boolean. Returns true if global work managers should be added to the OSGi service registry.

17.3.1.1 Configuring OSGi Framework Instance From Administration Console

You can configure an OSGi framework from the WebLogic Server Administration Console. Perform the following steps:

1. In the WebLogic Server Administration Console, expand **Services** in the left panel.
2. Click **OSGi Frameworks** in the left panel.
3. On the Summary of OSGi Frameworks page, click **New**.

If you have already created an OSGi framework, you can instead click **Clone** to use an existing framework as the basis for a new one.

4. On the Creating a New OSGi Framework page, name this framework instance. The name must be unique.
5. Click **Next**.
6. On the OSGi Framework Targets page, select the servers or clusters to which you would like to deploy this OSGi framework.
7. Click **Finish**.

8. On the Summary of OSGi Frameworks page, select the framework you just created.
9. On the Settings for Framework page, examine the defaults to make sure that they are correct for your environment. See [Table 17-1](#) for a description of the attributes.

See "Configure OSGi Frameworks" in the *Oracle WebLogic Server Administration Console Online Help*.

17.3.1.2 Configuring OSGi Framework Instance From config.xml

[Example 17-1](#) shows an example of updating config.xml to add the OSGi framework to be used by WebLogic Server. Add the <osgi-framework> element just before the </domain> element.

If you need to add multiple OSGi framework instances, add multiple <osgi-framework> elements. Remember that each <name> element must be unique within the server.

After you add this element, you must reboot the WebLogic Server instance.

Example 17-1 Configuring OSGi Framework Instance From config.xml

```
<osgi-framework>
  <name>test-osgi-frame</name>
  <target>AdminServer</target>
</osgi-framework>
```

17.3.1.3 Configuring OSGi Framework Instance From WLST

[Example 17-2](#) shows an example of using WLST to add the OSGi framework to be used by the WebLogic Server instance.

Example 17-2 Configuring OSGi Framework Instance From WLST

```
java weblogic.WLST

connect('weblogic', 'password')
edit()
startEdit()
wls:/mydomain/edit !> cmo.createOsgiFramework('test-osgi-frame')
[MBeanServerInvocationHandler] com.bea.Name=test-osgi-frame,Type=OsgiFramework
targetServer=cmo.lookupServer('AdminServer')
cd('OsgiFrameworks')
cd('test-osgi-frame')
cmo.addTarget(targetServer)
wls:/mydomain/edit !> save()
wls:/mydomain/edit !> activate()
wls:/mydomain/edit/OsgiFrameworks> ls('a')
drw-   test-osgi-frame
wls:/mydomain/edit/OsgiFrameworks> cd('test-osgi-frame')
wls:/mydomain/edit/OsgiFrameworks/test-osgi-frame> ls('a')
-rw-   DeployInstallationBundles           populate
-rw-   DeploymentOrder                    1000
-r--   DynamicallyCreated                  false
-rw-   FactoryImplementationClass          org.apache.felix.framework.F
rameworkFactory
-r--   Id                                   0
-rw-   InitProperties                       null
-rw-   Name                                 test-osgi-frame
-rw-   Notes                                null
-rw-   OrgOsgiFrameworkBootdelegation     null
```

```

-rw-  OrgOsgiFrameworkSystemPackagesExtra    null
-rw-  RegisterGlobalDataSources              true
-rw-  RegisterGlobalWorkManagers            true
-r--  Type                                   OsgiFramework

```

17.3.1.4 Configuring OSGi Framework Instance from a Java Program

[Example 17-3](#) shows an example of using a Java program to add the OSGi framework to be used by the WebLogic Server instance. Comments in the code describe each operation.

Example 17-3 Configuring OSGi Framework from Java Program

```

/**...imports omitted
*/
/**
 * Create an OSGi framework instance with the designated name
 *
 * @param frameworkName
 */
protected void createOSGiFrameworkInstance(String frameworkName) {
    createOSGiFrameworkInstance(frameworkName, null, null, null, null, null);
}

protected void createOSGiFrameworkInstance(String frameworkName,
                                           String isRegisterGlobalWorkManagers,
                                           String isRegisterGlobalDataSources,
                                           String deployInstallationBundles,
                                           String orgOsgiFrameworkBootdelegation,
                                           String orgOsgiFrameworkSystemPackagesExtra) {
    createOSGiFrameworkInstance(frameworkName,
                                null,
                                isRegisterGlobalWorkManagers,
                                isRegisterGlobalDataSources,
                                deployInstallationBundles,
                                orgOsgiFrameworkBootdelegation,
                                orgOsgiFrameworkSystemPackagesExtra);
}

/**
 * Create a fresh framework
 *
 * @param isRegisterGlobalWorkManagers
 * @param isRegisterGlobalDataSources
 * @param deployInstallationBundles
 * @param orgOsgiFrameworkBootdelegation
 * @param orgOsgiFrameworkSystemPackagesExtra
 */
protected void createOSGiFrameworkInstance(String frameworkName,
                                           Properties initProp,
                                           String isRegisterGlobalWorkManagers,
                                           String isRegisterGlobalDataSources,
                                           String deployInstallationBundles,
                                           String orgOsgiFrameworkBootdelegation,
                                           String orgOsgiFrameworkSystemPackagesExtra) {

    frameworkInstances.add(frameworkName);
}

```

```

if (initProp == null) {
    initProp = new Properties();
}
initProp.setProperty("wlstest.framework.instance.name", frameworkName);
//initProp.setProperty("felix.cache.locking", "false");
//initProp.setProperty("org.osgi.framework.storage.clean", "onFirstInit");

MBeanServerConnection connection = null;

try {

    // Initiate the necessary MBean facilities.
    connection = initConnection();
    // Switch the edit session on.
    ObjectName domainMBean = startEditSession(connection);

    // Get the current WebLogic server MBean:
    ObjectName serverMBean = null;
    ObjectName[] serverMBeans = (ObjectName[]) connection.getAttribute(domainMBean, "Servers");
    for (ObjectName objectName : serverMBeans) {
        log("found server: " + objectName);
        serverMBean = objectName;
    }

    // Get or create an OsgiFrameworkMBean:
    ObjectName osgiFrameworkMBean = null;
    ObjectName[] osgiFrameworkMBeans = (ObjectName[]) connection.getAttribute(domainMBean,
"OsgiFrameworks");
    log("osgiFrameworkMBeans.length=" + osgiFrameworkMBeans.length);
    for (ObjectName objectName : osgiFrameworkMBeans) {
        String osgiFrameworkName = (String) connection.getAttribute(objectName, "Name");
        log("-----> " + osgiFrameworkName);
        if (osgiFrameworkName.equals(frameworkName)) {
            osgiFrameworkMBean = objectName;
            log("Found OSGi framework instance: " + frameworkName);
            break;
        }
    }

    if (osgiFrameworkMBean != null) {
        log("Will destroy the framework instance: " + osgiFrameworkMBean);
        connection.invoke(osgiFrameworkMBean,
            "removeTarget",
            new Object[] { serverMBean },
            new String[] { "javax.management.ObjectName" });
        connection.invoke(domainMBean,
            "destroyOsgiFramework",
            new Object[] { osgiFrameworkMBean },
            new String[] { "javax.management.ObjectName" });
    }

    log("Will create a new framework instance from scratch");
    osgiFrameworkMBean = (ObjectName) connection.invoke(domainMBean,
        "createOsgiFramework",
        new Object[] { frameworkName },
        new String[] { "java.lang.String" });

    // Set common properties:
    if (initProp != null) {
        Attribute initPropAttr = new Attribute("InitProperties", initProp);

```

```

        connection.setAttribute(osgiFrameworkMBean, initPropAttr);
    }
    Attribute systemPackagesExtraAttr = new Attribute("OrgOsgiFrameworkSystemPackagesExtra",
                                                    "javax.naming,weblogic.work,javax.sql");
    connection.setAttribute(osgiFrameworkMBean, systemPackagesExtraAttr);
    connection.invoke(osgiFrameworkMBean,
                    "addTarget",
                    new Object[] { serverMBean },
                    new String[] { "javax.management.ObjectName" });

    // Set individual property to the OSGi framework instance:
    if (isRegisterGlobalWorkManagers != null) {
        Attribute attr = new Attribute("RegisterGlobalWorkManagers",
                                      Boolean.parseBoolean(isRegisterGlobalWorkManagers));
        connection.setAttribute(osgiFrameworkMBean, attr);
    }

    if (isRegisterGlobalDataSources != null) {
        Attribute attr = new Attribute("RegisterGlobalDataSources",
                                      Boolean.parseBoolean(isRegisterGlobalDataSources));
        connection.setAttribute(osgiFrameworkMBean, attr);
    }

    if (deployInstallationBundles != null) {
        Attribute attr = new Attribute("DeployInstallationBundles", deployInstallationBundles);
        connection.setAttribute(osgiFrameworkMBean, attr);
    }

    if (orgOsgiFrameworkBootdelegation != null) {
        Attribute attr = new Attribute("OrgOsgiFrameworkBootdelegation",
                                      orgOsgiFrameworkBootdelegation);
        connection.setAttribute(osgiFrameworkMBean, attr);
    }

    if (orgOsgiFrameworkSystemPackagesExtra != null) {
        Attribute attr = new Attribute("OrgOsgiFrameworkSystemPackagesExtra",
                                      orgOsgiFrameworkSystemPackagesExtra);
        connection.setAttribute(osgiFrameworkMBean, attr);
    }

    MBeanInfo mi = connection.getMBeanInfo(osgiFrameworkMBean);
    log("Attributes are as below:");
    for (MBeanAttributeInfo mai : mi.getAttributes()) {
        Object value = connection.getAttribute(osgiFrameworkMBean, mai.getName());
        System.out.printf("    %-40s = %s\n", mai.getName(), value);
    }

    // Save your changes
    ObjectName cfgMgr = (ObjectName) connection.getAttribute(service, "ConfigurationManager");
    connection.invoke(cfgMgr, "save", null, null);

```

17.3.1.5 Parameter Required for Installing Bundles in the Framework

The `OsgiFrameworkMBean` `MBean` `Deploy Installation Bundles` attribute controls whether or not bundles present in the `osgi-lib` directory (described later in this chapter in [Section 17.5.2, "Deploying OSGi Bundles in the osgi-lib Directory"](#)) are actually installed into the framework.

The `Deploy Installation Bundles` parameter accepts the following values:

- `ignore` — None of the bundles in this directory are installed and started.

- `populate` — The bundles are installed and started if possible. This is the default. Furthermore, a few extra packages are added to the boot delegation classpath parameters in order to enable the bundles in the `osgi-lib` directory if they are not already there.

It is not be considered a failure that causes the system to not boot if these bundles do not properly resolve and therefore cannot be started.

17.3.2 Configuring OSGi Framework Persistence

OSGi has a persistence mechanism, described in <http://www.osgi.org/javadoc/r4v43/org/osgi/framework/launch/Framework.html>, in which all installed bundles must be started in accordance with each bundle's persistent autostart setting.

This persistence mechanism is disabled by default. However, you can use the standard Felix Init property shown in [Table 17-1](#) to enable the OSGi persistence mechanism.

Note: WebLogic Server is not directly involved in the OSGi persistence mechanism. In particular, WebLogic Server does not fail the data over to other servers.

17.3.3 Using OSGi Services

You can make standard OSGi services available to your OSGi bundle. To do this, import the correct packages for the Felix framework and make sure that the application bundle has the required authorization.

These services are described in the OSGi Service Platform Core Specification (<http://www.osgi.org/Download/File?url=/download/r4v43/r4.core.pdf>) and include but are not limited to standard Framework supplied services such as the Package Admin Service, Conditional Permission Admin Service, or the StartLevel Service.

See the "Apache Felix Tutorial Example 1, Service Event Listener Bundle" for an example of creating a simple bundle that listens for OSGi service events.

17.4 Creating OSGi Bundles

You use the OSGi API bundle (provided with WebLogic Server) to create your own OSGi bundle.

See the "Apache Felix Tutorial Example 1, Service Event Listener Bundle" for an example of creating a simple bundle. As described in this example, the `Import-Package` attribute of the manifest file informs the framework of the bundle's dependencies on external packages. All bundles with an activator must import `org.osgi.framework` because it contains the core OSGi class definitions.

17.5 Deploying OSGi Bundles

This section includes the following subsections:

- [Section 17.5.1, "Preparing to Deploy an OSGi Bundle on a Target System"](#)
- [Section 17.5.2, "Deploying OSGi Bundles in the osgi-lib Directory"](#)

17.5.1 Preparing to Deploy an OSGi Bundle on a Target System

You can deploy OSGi bundles from inside a JAR, EAR, or WAR file, as appropriate for your application.

Before you do this, you must first specify which OSGi framework you want your bundle to use, and identify the bundle to WebLogic Server.

Note: If the OSGi framework instance you specify does not exist on the target server, the OSGi bundle fails to deploy.

How you do this depends on whether your bundle is inside a WAR file or an EAR file:

- WAR — The framework instance and bundle name must be in an element in the Web application's `weblogic.xml` deployment descriptor file.
- EAR — The framework instance and bundle name must be in an element in the application's `weblogic-application.xml` deployment descriptor file.

If the EAR file contains WAR files, then the bundles inside the WAR files are deployed using the `weblogic.xml` deployment descriptor file from the embedded WAR files.

The sections that follow describe the required steps in detail.

For more information about WebLogic Server deployment descriptors, see *Deploying Applications to Oracle WebLogic Server*.

17.5.1.1 Preparing to Deploy Bundles as Enterprise Applications

Before you deploy your OSGi bundle, you must first:

1. Use either the `DOMAIN_HOME\config\config.xml` deployment descriptor file or WLST to add an entry for the OSGi framework, as described in [Section 17.3.1, "Configuring OSGi Framework Instances"](#).
2. In the EAR file that contains the OSGi bundle, add both the name of the OSGi framework and the name of the bundle itself to the `weblogic-application.xml` deployment descriptor file.

[Example 17-1](#) shows an example of updating `config.xml` to add the OSGi framework used by the WebLogic Server.

[Example 17-4](#) shows an example of updating `weblogic-application.xml` to add both the name of the OSGi framework and the name and location of the bundle.

Example 17-4 Adding the Framework and Bundle to `weblogic-application.xml`

```
<osgi-framework-reference>
  <name>test-osgi-frame</name>
  <application-bundle-symbolic-name>com.oracle.weblogic.test.client
</application-bundle-symbolic-name>
  <bundles-directory>rashi/osgi-lib</bundles-directory>
</osgi-framework-reference>
```

The stanza in [Example 17-4](#) tells the WebLogic Server to attach to the OSGi framework named "test-osgi-frame" and to find the bundle in that server with the symbolic name `com.oracle.weblogic.test.client` in order to find classes from that OSGi framework.

17.5.1.2 Preparing to Deploy Bundles as Web Applications

Before you install your bundle as a WAR file, you must first:

1. Use either the `DOMAIN_HOME\config\config.xml` deployment descriptor file or WLST to add an entry for the OSGi framework, as described in [Section 17.3.1,](#)

"Configuring OSGi Framework Instances".

2. Add both the name of the OSGi framework and the name of the bundle itself to the web application's `weblogic.xml` deployment descriptor file.

[Example 17-1](#) shows an example of updating `config.xml` to add the OSGi framework used by the WebLogic Server.

[Example 17-5](#) shows an example of updating `weblogic.xml` to add both the name of the OSGi framework and the name and location of the bundle.

Example 17-5 Adding the Framework and Bundle to weblogic.xml

```
<osgi-framework-reference>
  <name>test-osgi-frame</name>
  <application-bundle-symbolic-name>com.oracle.weblogic.test.client
</application-bundle-symbolic-name>
  <bundles-directory>rashi/osgi-lib</bundles-directory>
</osgi-framework-reference>
```

The stanza in [Example 17-4](#) tells the WebLogic Server to attach to the OSGi framework named "test-osgi-frame" and to find the bundle in that server with the symbolic name `com.oracle.weblogic.test.client` in order to find classes from that OSGi framework.

17.5.1.3 Global Work Managers

Work Managers prioritize work based on rules you define and by monitoring actual run time performance statistics. This information is then used to optimize the performance of your application. See "Using Work Managers to Optimize Scheduled Work" in *Administering Server Environments for Oracle WebLogic Server*.

The OSGi implementation can take advantage of global work managers if the Register Global Work Managers MBean attribute is set to true, as described in [Table 17-1](#).

You can determine which global work manager is in use from a Java application, as shown in [Example 17-7](#).

Example 17-6 Determining Global Work Managers

```
// Get the global scoped work manager service:
ServiceReference[] refWmSvcs = bc.getServiceReferences(WorkManager.class.getCanonicalName(),
                                                    "(name=GlobalScopedWorkManager)");

if (refWmSvcs != null) {
  logger.setAttribute(frameworkInstanceName, bundleIdentifier + "_WorkManager_Count",
refWmSvcs.length);
  for (int i = 0; i < refWmSvcs.length; i++) {
    ServiceReference refWmSvc = refWmSvcs[i];
    WorkManager wm = (WorkManager) bc.getService(refWmSvc);
    logger.setAttribute(frameworkInstanceName, bundleIdentifier + "_WorkManager" + (i + 1),
wm.getName());
    bc.ungetService(refWmSvc);
  }
}
```

17.5.1.4 Global Data Sources

In WebLogic Server, you can configure database connectivity by configuring JDBC data sources and multi data sources and then targeting or deploying the JDBC

resources to servers or clusters in your WebLogic domain, as described in WebLogic Server Data Sources in *Understanding Oracle WebLogic Server*.

The OSGi implementation can take advantage of global data sources if the Register Global Data Sources MBean attribute is set to true, as described in [Table 17-1](#).

You can determine which global data source is in use from a Java application, as shown in [Example 17-7](#).

Example 17-7 Determining Global Data Sources

```
// Get the global data source services:
ServiceReference[] refDsSvcs =
bc.getServiceReferences(DataSource.class.getCanonicalName(), "(name=OsgiDS)");
if (refDsSvcs != null) {
    logger.setAttribute(frameworkInstanceName, bundleIdentifier + "_DataSource_
Count", refDsSvcs.length);
    for (int i = 0; i < refDsSvcs.length; i++) {
        String data = null;
        ServiceReference refDsSvc = refDsSvcs[i];
        DataSource ds = (DataSource) bc.getService(refDsSvc);
        Connection conn = null;
        Statement stmt = null;
        ResultSet rs = null;
        try {
            conn = ds.getConnection();
            stmt = conn.createStatement();
            rs = stmt.executeQuery("select * from dual");
            rs.next();
            data = rs.getString(0);
        } catch (SQLException e) {
```

17.5.2 Deploying OSGi Bundles in the `osgi-lib` Directory

Note: The `OsgiFrameWorkMBean` MBean `Deploy Installation Bundles` attribute controls whether or not bundles present in the `osgi-lib` directory are actually installed, as described in [Section 17.3.1.5, "Parameter Required for Installing Bundles in the Framework"](#). This attribute is true by default, and the bundles are installed.

To deploy a bundle with the start-level of 1, create the `WL_HOME/server/osgi-lib` directory if it does not already exist, and then copy the archive file (EAR, WAR) file to it.

Any files in this directory that end with `.jar`, `.ear`, or `.war` are considered an OSGi bundle to be installed into a framework when it starts.

`WL_HOME/server/osgi-lib` is consulted only when the server first boots, and is not monitored for changes thereafter. If you add a new OSGi bundle to the `WL_HOME/server/osgi-lib` directory and want to deploy it, you must reboot WebLogic Server.

17.5.2.1 Setting the Start Level and Run Level for a Bundle

To deploy a bundle with the start-level of 1, copy the archive file (EAR, WAR) file to the `WL_HOME/server/osgi-lib` directory.

In addition, the `WL_HOME/server/osgi-lib` directory supports a start- and run-level scheme based on subdirectories.

If you create subdirectories with names that begin with a number between 1 and 32K (for example 2, 3, 4), then the archive files under those directories are installed and started with the given run-level.

17.6 Accessing Deployed Bundle Objects From JNDI

After the OSGi server has been booted, a bundle object is placed into the local server JNDI tree. Applications can therefore get this bundle from JNDI and thereafter use that as the entry point into the OSGi system.

The `org.osgi.framework.Bundle` is placed into the `java:app/osgi/Bundle` JNDI environment of the application.

One specific OSGi bundle from the chosen framework instance can be used in the application classloader hierarchy.

[Example 17-8](#) shows how to access a bundle that you create from JNDI.

Example 17-8 Accessing Your OSGi Bundle From JNDI

```
public static final String BUNDLE_JNDI_NAME = "java:app/osgi/Bundle";
...
String bundleSymbolicName = null;

Bundle bundle = null;
OsgiInfo info = new OsgiInfo();
List<String> errorMessages = new ArrayList<String>();

try {
    Context initCtx = new InitialContext();
    bundle = (Bundle) initCtx.lookup(Constants.BUNDLE_JNDI_NAME);
} catch (NamingException e) {
    errorMessages.add(e.toString());
    System.out.println("Failed to lookup bundle from JNDI due to " + e);
}

if (bundle != null) {

    bundleSymbolicName = bundle.getSymbolicName() + "_" + bundle.getVersion();
    info.setCurrentBundle(bundleSymbolicName);

    BundleContext bc = bundle.getBundleContext();

    if (bc != null) {

        // Get the start level service:
        StartLevel startLevelSvc = null;
        ServiceReference startLevelSr =
bc.getServiceReference("org.osgi.service.startlevel.StartLevel");
        if (startLevelSr != null) {
            startLevelSvc = (StartLevel) bc.getService(startLevelSr);
        }
    }
}
```

```

List<String> allInstalledBundles = new ArrayList<String>();
List<String> allActivatedBundles = new ArrayList<String>();
Map<String, List<String>> services = new HashMap<String, List<String>>();
Map<String, String> startLevels = new HashMap<String, String>();

for (Bundle b : bc.getBundles()) {

    // Collect all the installed and activated bundles:
    String bundleId = b.getSymbolicName() + "_" + b.getVersion();
    allInstalledBundles.add(bundleId);
    if (b.getState() == Bundle.ACTIVE) {
        allActivatedBundles.add(bundleId);
    }

    // Collect the registered services:
    ServiceReference[] srs = b.getRegisteredServices();
    if (srs != null) {
        List<String> list = new ArrayList<String>();
        for (ServiceReference sr : srs) {
            list.add(sr + "-->" + bc.getService(sr));
        }
        services.put(bundleId, list);
    }

    // Collect the start levels:
    if (startLevelSvc != null) {
        startLevels.put(bundleId, startLevelSvc.getBundleStartLevel(b) + "");
    }
}

info.setAllInstalledBundles(allInstalledBundles);
info.setAllActivatedBundles(allActivatedBundles);
info.setRegisteredServices(services);
info.setStartLevels(startLevels);

// Query the work manager services:
List<String> workManagers = new ArrayList<String>();
try {
    ServiceReference[] wmSrs = bc.getServiceReferences(WorkManager.class.getCanonicalName(),
null);
    if (wmSrs != null) {
        for (ServiceReference sr : wmSrs) {
            WorkManager wm = (WorkManager) bc.getService(sr);
            workManagers.add(wm.getName());
        }
    }
} catch (InvalidSyntaxException e) {
    e.printStackTrace(System.out);
}
info.setWorkManagers(workManagers);

// Query the data source services:
List<String> dataSources = new ArrayList<String>();
try {
    ServiceReference[] dsSrs = bc.getServiceReferences(DataSource.class.getCanonicalName(),
null);
    if (dsSrs != null) {
        for (ServiceReference sr : dsSrs) {
            dataSources.add(sr.getProperty("name").toString());
        }
    }
}

```

```

    }
    } catch (InvalidSyntaxException e) {
        e.printStackTrace(System.out);
    }
    info.setDataSources(dataSources);

}

String bundleFileName = null;
try {
    BundleIntrospect introspection = new BundleIntrospect();
    bundleFileName = introspection.whichBundleFile();
    info.setCurrentBundleFileName(bundleFileName);
} catch (Throwable e) {
    errorMessages.add(e.toString());
    //e.printStackTrace(System.out);
}
info.setErrorMessages(errorMessages);

return info;

}
}

```

17.7 Using OSGi Logging Via WebLogic Server

The Apache Felix implementation of the OSGi Log service, version 1.0.0, is installed by default in the installation directory `WL_HOME/server/osgi-lib`.

An OSGi bundle `com.oracle.weblogic.osgi.logger_1.0.0.jar` is also installed in `WL_HOME/server/osgi-lib`. This bundle registers itself with the OSGi logging service and sends logs from the OSGi logger to the WebLogic Server logger.

The logger system name is `OSGiForApps`. The messages severity levels are mapped between OSGi and WebLogic Server as shown in [Table 17-2](#).

Table 17-2 OSGi and WebLogic Server Logging Severity Mapping

OSGi Severity Levels	WebLogic Server Severity Level
<code>LogLevel.LOG_ERROR</code>	<code>Severities.ERROR</code>
<code>LogLevel.LOG_WARNING</code>	<code>Severities.WARNING</code>
<code>LogLevel.LOG_INFO</code>	<code>Severities.INFO</code>
<code>LogLevel.LOG_DEBUG</code>	<code>Severities.DEBUG</code>

17.8 Configuring a Filtering ClassLoader for OSGi Bundles

You can use a filtering classloader to specify the use of alternate library versions that are deployed as OSGi bundles.

To configure the `FilteringClassLoader` to specify that a certain package is loaded from an application, add a `prefer-application-packages` descriptor element to `weblogic-application.xml`, which details the list of packages to be loaded from the application. The following example specifies that `org.apache.log4j.*` and `antlr.*` packages are loaded from the application, not the system classloader:

```
<prefer-application-packages>
```

```
<package-name>org.apache.log4j.*</package-name>  
<package-name>antlr.*</package-name>  
</prefer-application-packages>
```

Place packages in `WEB-INF/lib` or in `WEB-INF/osgi-lib` if the package is an OSGi bundle. You can either add OSGi bundle dependencies directly to `WEB-INF/osgi-lib` or configure the `org.osgi.framework.system.packages.extra` property (see [Table 17-1](#)) in your OSGi framework instance to export the necessary javax packages that the application needs.

For more information on filtering classloaders, see "Using a Filtering ClassLoader".

17.9 OSGi Example

WebLogic Server includes an example that demonstrates how to deploy OSGi bundles to WebLogic Server. If you installed the WebLogic Server examples, the OSGi example source code is available in `ORACLE_HOME\wlserver\samples\server\examples\src\examples\osgi\osgiApp`, where `ORACLE_HOME` represents the directory in which you installed WebLogic Server. For more information about the WebLogic Server code examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

There are two simple bundles: client and server. The server bundle (`ServerBundle`) exports a packet that the client bundle (`ClientBundle`) imports.

The example produces an HTML page that displays the deployed OSGi bundles.

Using the WebSocket Protocol in WebLogic Server

WebLogic Server supports the WebSocket protocol (RFC 6455), which provides full-duplex communications between two peers over the TCP protocol. The WebLogic Server implementation of the WebSocket protocol and its accompanying API enable you to develop and deploy applications that communicate bidirectionally with clients. Although you can use the WebSocket protocol for any type of client-server communication, the implementation is most commonly used to communicate with browsers running Web pages that use the World Wide Web Consortium (W3C) JavaScript WebSocket API. The WebLogic Server implementation of the WebSocket protocol also supports Java clients.

This chapter includes the following sections:

- [Section 18.1, "Understanding the WebSocket Protocol"](#)
- [Section 18.2, "Understanding the WebLogic Server WebSocket Implementation"](#)
- [Section 18.3, "Overview of Creating a WebSocket Application"](#)
- [Section 18.4, "Creating an Endpoint"](#)
- [Section 18.5, "Handling Life Cycle Events for a WebSocket Connection"](#)
- [Section 18.6, "Defining, Injecting, and Accessing a Resource for a WebSocket Endpoint"](#)
- [Section 18.7, "Sending a Message"](#)
- [Section 18.8, "Encoding and Decoding a WebSocket Message"](#)
- [Section 18.9, "Specifying a Part of an Endpoint Deployment URI as an Application Parameter"](#)
- [Section 18.10, "Maintaining Client State"](#)
- [Section 18.11, "Configuring a Server Endpoint Programmatically"](#)
- [Section 18.12, "Building Applications that Use the Java API for WebSocket"](#)
- [Section 18.13, "Deploying a WebSocket Application"](#)
- [Section 18.14, "Monitoring WebSocket Applications"](#)
- [Section 18.15, "Using WebSockets with Proxy Servers"](#)
- [Section 18.16, "Writing a WebSocket Client"](#)
- [Section 18.17, "Securing a WebSocket Application"](#)
- [Section 18.18, "Enabling Protocol Fallback for WebSocket Messaging"](#)

- [Section 18.19, "Migrating an Application to the JSR 356 Java API for WebSocket from the Deprecated API"](#)
- [Section 18.20, "Example of Using the Java API for WebSocket with WebLogic Server"](#)

18.1 Understanding the WebSocket Protocol

WebSocket is an application protocol that provides simultaneous two-way communication over a single TCP connection between a client and a server. The WebSocket protocol enables the client and the server to send data independently. As part of the HTML5 specification (<http://www.w3.org/TR/html5/>), the WebSocket Protocol is supported by most browsers. A browser that supports the WebSocket protocol provides a JavaScript API to connect to endpoints, send messages, and assign callback methods for WebSocket events (such as opened connections, received messages, and closed connections).

For general information about the WebSocket Protocol, see <http://tools.ietf.org/html/rfc6455>.

18.1.1 Limitations of the HTTP Request-Response Model

In the traditional request-response model used in HTTP, the client requests resources and the server provides responses. The exchange is always initiated by the client; the server cannot send any data without the client requesting it first. This model worked well for the World Wide Web when clients made occasional requests for documents that changed infrequently, but the limitations of this approach are increasingly apparent as content changes quickly and users expect a more interactive experience on the web. The WebSocket protocol addresses these limitations by providing a full-duplex communication channel between the client and the server. Combined with other client technologies, such as JavaScript and HTML5, WebSocket enables web applications to deliver a richer user experience.

18.1.2 WebSocket Endpoints

In a WebSocket application, the server publishes a WebSocket **endpoint** and the client uses the endpoint's URI to connect to the server.

A WebSocket endpoint is represented by a URI in one of the following formats:

```
ws://host:port/path?query  
wss://host:port/path?query
```

The `ws` scheme represents an unencrypted WebSocket connection.

The `wss` scheme represents an encrypted WebSocket connection.

The remaining components in these formats are as follows:

host

The host as defined in [RFC3986], Section 3.2.2.

port

Optional. The port as defined in [RFC3986], Section 3.2.3. The default port number is 80 for unencrypted connections and 443 for encrypted connections.

path

The path as defined in [RFC3986], Section 3.3. In a WebSocket endpoint, the path indicates the location of the endpoint within a server.

query

Optional. A query as defined in [RFC3986], Section 3.4.

18.1.3 Handshake Requests in the WebSocket Protocol

To initiate a WebSocket connection, the client sends a handshake request to a WebSocket endpoint that the server has published. The client locates the endpoint by using the end point's URI. The connection is established if the handshake request passes validation, and the server accepts the request. The handshake is compatible with existing HTTP-based infrastructure: web servers interpret the handshake as an HTTP connection upgrade request.

[Example 18–1](#) shows a handshake request from a client.

Example 18–1 Handshake Request from a WebSocket Client

```
GET /path/to/websocket/endpoint HTTP/1.1
Host: localhost
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Key: xqBt3ImNzJbYqRINxEFlkg==
Origin: http://localhost
Sec-WebSocket-Version: 13
```

[Example 18–2](#) shows a handshake from a server in response to a handshake request from a client.

Example 18–2 Server Response to a Handshake Request from a WebSocket Client

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: K7DJLdLooIwIG/MQpvWFB3y3FE8=
```

The server applies a known operation to the value of the `Sec-WebSocket-Key` header to generate the value of the `Sec-WebSocket-Accept` header. The client applies the same operation to the value of the `Sec-WebSocket-Key` header. If the result matches the value received from the server, the connection is established successfully. The client and the server can send messages to each other after a successful handshake.

18.1.4 Messaging and Data Transfer in the WebSocket Protocol

The WebSocket protocol is symmetrical after the connection has been established: the client and the WebLogic Server instance can send messages to each other at any time while the connection is open, and they can close the connection at any time. Typically, clients connect to only one server, but servers accept connections from multiple clients.

WebSocket supports text messages (encoded as UTF-8) and binary messages. The control frames in WebSocket are *close*, *ping*, and *pong* (a response to a *ping* frame). Ping and pong frames may also contain application data.

18.2 Understanding the WebLogic Server WebSocket Implementation

The WebLogic Server WebSocket implementation supports JSR 356 Java API for WebSocket. For more information about the Java API for WebSocket, see the JSR 356 specification:

<http://www.jcp.org/en/jsr/detail?id=356>

Note: The proprietary WebLogic Server WebSocket API that was introduced in release 12.1.2 is deprecated but remains supported for backward compatibility.

Although the JSR 356 Java API for WebSocket coexists with the proprietary WebLogic Server WebSocket API, an application cannot contain calls to both APIs. Only one of the APIs can be used in an application.

Information about how to use the deprecated API is available in the documentation for Oracle WebLogic Server 12c (12.1.2) in "Using WebSockets in WebLogic Server" in *Developing Applications for Oracle WebLogic Server 12c (12.1.2)*.

The WebLogic Server WebSocket implementation includes the following components:

- [WebSocket Protocol Implementation](#)
- [WebLogic WebSocket Java API](#)
- [Protocol Fallback for WebSocket Messaging](#)
- [Sample WebSocket Applications](#)

18.2.1 WebSocket Protocol Implementation

The WebSocket protocol implementation in WebLogic Server is provided by the reference implementation of JSR 356 Java API for WebSocket. This implementation of the WebSocket protocol handles connection upgrades, establishes and manages connections, and handles exchanges with the client.

18.2.2 WebLogic WebSocket Java API

The WebLogic WebSocket API is provided by the reference implementation of JSR 356 Java API for WebSocket. This API consists of the following packages:

`javax.websocket.server`

This package contains annotations, classes, and interfaces to create and configure server endpoints.

`javax.websocket`

This package contains annotations, classes, interfaces, and exceptions that are common to client and server endpoints.

The API reference documentation for these packages is available in the following sections of the *Java EE 7 Specification APIs*:

- Package `javax.websocket`
- Package `javax.websocket.server`

18.2.3 Protocol Fallback for WebSocket Messaging

Protocol fallback provides a mechanism for using an alternative transport for WebSocket messaging when the WebSocket protocol is not supported. Typically the WebSocket protocol is not supported either because the WebSocket object is not available or because WebSocket frames are blocked by a firewall. In this release, the only supported alternative transport is HTTP Long Polling.

Protocol fallback enables you to rely on standard programming APIs to perform WebSocket messaging regardless of whether or not the runtime environment supports the WebSocket protocol. For more information, see [Enabling Protocol Fallback for WebSocket Messaging](#).

18.2.4 Sample WebSocket Applications

If the WebLogic Server Examples component is installed and configured on your machine, you can use the WebSocket examples to demonstrate using WebSockets in WebLogic Server. For more information about running these examples, see "Sample Applications and Code Examples" in *Understanding Oracle WebLogic Server*.

18.3 Overview of Creating a WebSocket Application

The Java API for WebSocket (JSR-356) enables you to create, configure, and deploy WebSocket endpoints in web applications. The WebSocket client API specified in JSR-356 also enables you to access remote WebSocket endpoints from any Java application.

The process for creating and deploying a WebSocket endpoint is as follows:

1. Create an endpoint class.
2. Implement the lifecycle methods of the endpoint.
3. Add your business logic to the endpoint.
4. Deploy the endpoint inside a web application.

18.4 Creating an Endpoint

The Java API for WebSocket enables you to create the following kinds of endpoints:

- Annotated endpoints
- Programmatic endpoints

The process is different for programmatic endpoints and annotated endpoints. In most cases, it is easier to create and deploy an annotated endpoint than a programmatic endpoint.

Note: As opposed to servlets, WebSocket endpoints are instantiated multiple times. The container creates one instance of an endpoint for each connection to its deployment URI. Each instance is associated with one and only one connection. This behavior facilitates keeping user state for each connection and simplifies development because only one thread is executing the code of an endpoint instance at any given time.

18.4.1 Creating an Annotated Endpoint

Creating an annotated endpoint enables you to handle life cycle events for a WebSocket connection by annotating methods of the endpoint class. For more information, see [Handling Life Cycle Events in an Annotated WebSocket Endpoint](#). An annotated endpoint is deployed automatically with the application.

The Java API for WebSocket enables you to create annotated server endpoints and annotated client endpoints.

To create an annotated server endpoint:

1. Write a Plain Old Java Object (POJO) class to represent the server endpoint.
The class must have a public no-argument constructor.
2. Annotate the class declaration of the POJO class with the `javax.websocket.server.ServerEndpoint` annotation.
This annotation denotes that the class represents a WebSocket server endpoint.
3. Set the value element of the `ServerEndpoint` annotation to the relative path to which the endpoint is to be deployed.
The path must begin with a forward slash (/).

[Example 18–3](#) shows how to declare an annotated server endpoint class. For an example of how to declare a programmatic endpoint class to represent the same endpoint, see [Example 18–5](#).

Example 18–3 Declaring an Annotated Server Endpoint Class

This example declares the annotated server endpoint class `EchoEndpoint`. The endpoint is to be deployed to the `/echo` path relative to the application.

```
import javax.websocket.server.ServerEndpoint;
...
@ServerEndpoint("/echo")
public class EchoEndpoint {
    ...
}
```

To create an annotated client endpoint:

1. Write a Plain Old Java Object (POJO) class to represent the client endpoint.
The class can have a constructor that takes arguments. However, to connect such an endpoint to a server endpoint, you must use the variant of the `connectToServer` method that takes an instance. You cannot use the variant that takes a class. For more information, see [Connecting a Java WebSocket Client to a Server Endpoint](#).
2. Annotate the class declaration of the POJO class with the `javax.websocket.ClientEndpoint` annotation.
This annotation denotes that the class represents a WebSocket client endpoint.

[Example 18–4](#) shows how to declare an annotated client endpoint class.

Example 18–4 Declaring an Annotated Client Endpoint Class

This example declares the annotated client endpoint class `ExampleEndpoint`.

```
import javax.websocket.ClientEndpoint;
...
@ClientEndpoint
public class ExampleEndpoint {
    ...
}
```

18.4.2 Creating a Programmatic Endpoint

Creating a programmatic endpoint requires you to handle life cycle events for a WebSocket connection by overriding methods of the endpoint's superclass. For more information, see [Handling Life Cycle Events in a Programmatic WebSocket Endpoint](#). A programmatic endpoint is **not** deployed automatically with the application. You must deploy the endpoint explicitly. For more information, see [Specifying the Path Within an Application to a Programmatic Endpoint](#).

To create a programmatic endpoint, extend the `javax.websocket.Endpoint` class.

[Example 18–5](#) shows how to declare a programmatic endpoint class. For an example of how to declare an annotated endpoint class to represent the same endpoint, see [Example 18–3](#).

Example 18–5 Declaring a Programmatic Endpoint Class

This example declares the programmatic endpoint class `EchoEndpoint`. For an example that shows how to specify the path within an application to this endpoint, see [Example 18–6](#).

```
import javax.websocket.Endpoint;
...
public class EchoEndpoint extends Endpoint {
...
}
```

18.4.3 Specifying the Path Within an Application to a Programmatic Endpoint

To enable remote clients to connect to a programmatic endpoint, you must specify the path within an application to the endpoint.

To specify the path within an application to a programmatic endpoint:

1. Invoke the `javax.websocket.server.ServerEndpointConfig.Builder.create` static method to obtain an instance of the `javax.websocket.server.ServerEndpointConfig.Builder` class.

In the invocation of the `create` method, pass the following information as parameters to the method:

- The class of the endpoint
 - The path relative to the application at which the endpoint is to be available
2. Invoke the `build` method on the `ServerEndpointConfig.Builder` object that you obtained in the previous step.

When you deploy your application, the endpoint is available at the following URI:

```
ws://host:port/application/path
```

The replaceable items in this URI are as follows:

host

The host on which the application is running.

port

The port on which WebLogic Server listens for client requests.

application

The name with which the application is deployed.

path

The path that you specified in the invocation of the `create` method.

For example, the URI to the endpoint at the `/echo` path relative to the `/echoapp` application running on the local host is `ws://localhost:8890/echoapp/echo`.

[Example 18–6](#) shows how to perform this task in a single line of Java code.

Example 18–6 Specifying the Path Within an Application to a Programmatic Endpoint

This example specifies `/echo` as the path within an application to the programmatic endpoint `EchoEndpoint` from [Example 18–5](#).

```
import javax.websocket.server.ServerEndpointConfig.Builder;
...
ServerEndpointConfig.Builder.create(EchoEndpoint.class, "/echo").build();
...
```

18.5 Handling Life Cycle Events for a WebSocket Connection

How to handle life cycle events for a WebSocket connection depends on whether the endpoint of the connection is an annotated endpoint a programmatic endpoint. For more information, see:

- [Handling Life Cycle Events in an Annotated WebSocket Endpoint](#)
- [Handling Life Cycle Events in a Programmatic WebSocket Endpoint](#)

18.5.1 Handling Life Cycle Events in an Annotated WebSocket Endpoint

Handling a life cycle event in an annotated WebSocket involves the following tasks:

1. Adding a method to your endpoint class to handle the event

The allowed method parameters are defined by the annotation that you will use to designate the event.
2. Annotating the method declaration with the annotation that designates the event that the method is to handle.

[Table 18–1](#) lists the life cycle events in a WebSocket endpoint and the annotations available in the `javax.websocket` package to designate the methods that handle them. The examples in the table show the most common parameters for these methods. Each example in the table includes an optional `javax.websocket.Session` parameter. A `Session` object represents a conversation between a pair of WebSocket endpoints.

For details about the combinations of parameters that are allowed by an annotation, see the API reference documentation for the annotation.

Table 18–1 Annotations in `javax.websocket` for WebSocket Endpoint Lifecycle Events

Event	Annotation	Example
Connection opened	<code>OnOpen</code>	<code>@OnOpen</code> <pre>public void open(Session session, EndpointConfig conf) { }</pre>
Message received	<code>OnMessage</code>	<code>@OnMessage</code> <pre>public String message (String msg) { }</pre>

Table 18–1 (Cont.) Annotations in `javax.websocket` for WebSocket Endpoint Lifecycle

Event	Annotation	Example
Error	<code>OnError</code>	<code>@OnError</code> <pre>public void error(Session session, Throwable error) { }</pre>
Connection closed	<code>OnClose</code>	<code>@OnClose</code> <pre>public void close(Session session, CloseReason reason) { }</pre>

18.5.1.1 Handling a Connection Opened Event

Handle a connection opened event to notify users that a new WebSocket conversation has begun.

To handle a connection opened event, annotate the method for handling the event with the `OnOpen` annotation.

[Example 18–7](#) shows how to handle a connection opened event.

Example 18–7 Handling a Connection Opened Event

This example prints the identifier of the session when a WebSocket connection is opened.

```
import javax.websocket.OnOpen;
import javax.websocket.Session;
...
    @OnOpen
    public void openedConnection (Session session) {
        System.out.println("WebSocket opened: " + session.getId());
    }
...
```

18.5.1.2 Handling a Message Received Event

The Java API for WebSocket enables you to handle the following types of incoming messages:

- Text messages
- Binary messages
- Pong messages

To handle a message received event, perform the following steps for each type of incoming message that your application will receive:

1. Add a method to your endpoint class to handle the type of the incoming message. Ensure that the data type of the parameter for receiving the message is compatible with the type of the message as shown in the following table.

Message Type	Data Type of the Parameter for Receiving the Message
Text	<p>Any one of the following data types depending on how the message is to be received:</p> <ul style="list-style-type: none"> ■ To receive the whole message: <code>java.lang.String</code> ■ To receive the whole message converted to a Java primitive or class equivalent to that type: the primitive or class equivalent ■ To receive the message in parts: <code>String</code> and boolean pair ■ To receive the whole message as a blocking stream: <code>java.io.Reader</code> ■ To receive the message encoded as a Java object: any type for which the endpoint has a text decoder (<code>javax.websocket.Decoder.Text</code> or <code>javax.websocket.Decoder.TextStream</code>)
Binary	<p>Any one of the following data types depending on how the message is to be received:</p> <ul style="list-style-type: none"> ■ To receive the whole message: byte array or <code>java.nio.ByteBuffer</code> ■ To receive the message in parts: byte array and boolean pair, or <code>ByteBuffer</code> and boolean pair ■ To receive the whole message as a blocking stream: <code>java.io.InputStream</code> ■ To receive the message encoded as a Java object: any object type for which the endpoint has a binary decoder (<code>javax.websocket.Decoder.Binary</code> or <code>javax.websocket.Decoder.BinaryStream</code>)
Pong	<code>javax.websocket.PongMessage</code>

2. Annotate the method declaration with the `OnMessage` annotation.

You can have at most three methods annotated with `@OnMessage` in an endpoint, one method for each message type: text, binary, and pong.

Note: For an annotated endpoint, you add methods for handling incoming messages to your endpoint class. You are not required to create a separate message handler class. However, for a programmatic endpoint, you must create a separate message handler class.

To compare how to handle incoming messages for an annotated endpoint and a programmatic endpoint, see [Example 18–8](#) and [Example 18–12](#).

[Example 18–8](#) shows how to handle incoming text messages for an annotated endpoint.

Example 18–8 Handling Incoming Text Messages for an Annotated Endpoint

This example replies to every incoming text message by sending the message back to the peer of this endpoint. The method that is annotated with the `OnMessage` annotation is a method of the endpoint class, not a separate message handler class.

For an example of how to perform the same operation for a programmatic endpoint, see [Example 18–12](#).

```
import java.io.IOException;
```

```
import javax.websocket.OnMessage;
import javax.websocket.Session;
...
    @OnMessage
    public String onMessage(String msg) throws IOException {
        return msg;
    }
...

```

[Example 18–9](#) shows how to handle all types of incoming messages.

Example 18–9 Handling all Types of Incoming Messages

This example handles incoming text messages, binary messages, and pong messages. Text messages are received whole as `String` objects. Binary messages are received whole as `ByteBuffer` objects.

```
import java.nio.ByteBuffer;

import javax.websocket.OnMessage;
import javax.websocket.PongMessage;
import javax.websocket.Session;
...
    @OnMessage
    public void textMessage(Session session, String msg) {
        System.out.println("Text message: " + msg);
    }
    @OnMessage
    public void binaryMessage(Session session, ByteBuffer msg) {
        System.out.println("Binary message: " + msg.toString());
    }
    @OnMessage
    public void pongMessage(Session session, PongMessage msg) {
        System.out.println("Pong message: " +
            msg.getApplicationData().toString());
    }
...

```

18.5.1.3 Handling an Error Event

You need handle only error events that are not modeled in the WebSocket protocol, for example:

- Connection problems
- Runtime errors from message handlers
- Conversion errors in the decoding of messages

To handle an error event, annotate the method for handling the event with the `OnError` annotation.

[Example 18–10](#) shows how to handle an error event.

Example 18–10 Handling an Error Event

This example prints a stack trace in response to an error event.

```
import javax.websocket.OnError;
import javax.websocket.Session;
...

```

```

@OnError
public void error(Session session, Throwable t) {
    t.printStackTrace();
    ...
}

```

18.5.1.4 Handling a Connection Closed Event

You need handle a connection closed event only if you require some special processing before the connection is closed, for example, retrieving session attributes such as the ID, or any application data that the session holds before the data becomes unavailable after the connection is closed.

To handle a connection closed event, annotate the method for handling the event with the `OnClose` annotation.

[Example 18–11](#) shows how to handle a connection closed event.

Example 18–11 Handling a Connection Closed Event

This example prints the message `Someone is disconnecting...` in response to a connection closed event.

```

import javax.websocket.OnClose;
import javax.websocket.Session;
...
@OnClose
public void bye(Session remote) {
    System.out.println("Someone is disconnecting...");
}
...

```

18.5.2 Handling Life Cycle Events in a Programmatic WebSocket Endpoint

[Table 18–2](#) summarizes how to handle lifecycle events in a programmatic WebSocket endpoint.

Table 18–2 Handling Life Cycle Events in a Programmatic WebSocket Endpoint

Event	How to Handle
Connection opened	Override the abstract <code>onOpen</code> method of the <code>Endpoint</code> class.
Message received	<ol style="list-style-type: none"> 1. Declare that your endpoint class implements the message handler interface <code>javax.websocket.MessageHandler.Partial</code> or <code>javax.websocket.MessageHandler.Whole</code>. 2. Register your message handler by invoking the <code>addMessageHandler</code> method of your endpoint's <code>Session</code> object. 3. Implement the <code>onMessage</code> method of the message handler interface that your endpoint class implements.
Error	<p>Optional: Override the <code>onError</code> method of the <code>Endpoint</code> class.</p> <p>If you do not override this method, the <code>onError</code> method that your endpoint inherits from the <code>Endpoint</code> class is called when an error occurs.</p>
Connection closed	<p>Optional: Override the <code>onClose</code> method of the <code>Endpoint</code> class.</p> <p>If you do not override this method, the <code>onClose</code> method that your endpoint inherits from the <code>Endpoint</code> class is called immediately before the connection is closed.</p>

[Example 18–12](#) shows how handle incoming text messages for a programmatic endpoint by handling connection opened events and message received events.

Example 18–12 Handling Incoming Text Messages for a Programmatic Endpoint

This example echoes every incoming text message. The example overrides the `onOpen` method of the `Endpoint` class, which is the only abstract method of this class.

The `Session` parameter represents a conversation between this endpoint and the remote endpoint. The `addMessageHandler` method registers message handlers, and the `getBasicRemote` method returns an object that represents the remote endpoint.

The message handler is implemented as an anonymous inner class. The `onMessage` method of the message handler is invoked when the endpoint receives a text message.

For more information about sending a message, see [Sending a Message](#).

For an example of how to perform the same operation for an annotated endpoint, see [Example 18–8](#).

```
import java.io.IOException;
import javax.websocket.EndpointConfig;
import javax.websocket.MessageHandler;
import javax.websocket.Session;
...
@Override
public void onOpen(final Session session, EndpointConfig config) {
    session.addMessageHandler(new MessageHandler.Whole<String>() {
        @Override
        public void onMessage(String msg) {
            try {
                session.getBasicRemote().sendText(msg);
            } catch (IOException e) { ... }
        }
    });
}
...
```

18.6 Defining, Injecting, and Accessing a Resource for a WebSocket Endpoint

The Java API for WebSocket allows you to use Contexts and Dependency Injection (CDI) to inject and access a resource that a WebSocket endpoint requires. You can use the injected resource from within a method for handling a lifecycle event for a WebSocket connection.

For more information about CDI, see [Chapter 9, "Using Contexts and Dependency Injection for the Java EE Platform."](#)

To define, inject, and access a resource for a WebSocket endpoint:

1. Define a managed bean to represent the resource to inject.
For more information, see [Defining a Managed Bean](#).
2. In the endpoint class, inject the managed bean.
For more information, see [Injecting a Bean](#).
3. From within the relevant method, invoke methods of the injected bean as required.

The following examples show how to define, inject, and access a resource for a WebSocket endpoint:

- [Example 18–13](#)
- [Example 18–14](#)

Example 18–13 Defining a Managed Bean for a WebSocket Endpoint

This example defines the managed bean class `InjectedSimpleBean`.

```
import javax.annotation.PostConstruct;

public class InjectedSimpleBean {

    private static final String TEXT = " (from your server)";
    private boolean postConstructCalled = false;

    public String getText() {
        return postConstructCalled ? TEXT : null;
    }

    @PostConstruct
    public void postConstruct() {
        postConstructCalled = true;
    }

}
```

Example 18–14 Injecting and Accessing a Resource for a WebSocket Endpoint

This example injects an instance of the `InjectedSimpleBean` managed bean class into the server endpoint `SimpleEndpoint`. When the endpoint receives a message, it invokes the `getText` method on the injected bean. The method returns the text (sent from your server). The endpoint then sends back a message which is a concatenation of the original message and gathered data.

The `InjectedSimpleBean` managed bean class is defined in [Example 18–13](#).

```
import javax.websocket.OnMessage;
import javax.websocket.server.ServerEndpoint;

import javax.annotation.PostConstruct;
import javax.inject.Inject;

@ServerEndpoint(value = "/simple")
public class SimpleEndpoint {

    private boolean postConstructCalled = false;

    @Inject
    InjectedSimpleBean bean;

    @OnMessage
    public String echo(String message) {
        return postConstructCalled ?
            String.format("%s%s", message, bean.getText()) :
            "PostConstruct was not called";
    }

    @PostConstruct
```

```

public void postConstruct() {
    postConstructCalled = true;
}
}

```

18.7 Sending a Message

The Java API for WebSocket enables you to send the following types of message from an endpoint to its connected peers:

- Text messages
- Binary messages
- Ping frames

18.7.1 Sending a Message to a Single Peer of an Endpoint

To send a message to a single peer of an endpoint:

1. Obtain the `Session` object from the connection.

The `Session` object is available as a parameter in the lifecycle methods of the endpoint. How to obtain this object depends on whether the message that you are sending is a response to a message from a peer.

- If the message is a response, obtain the `Session` object from inside the method that received the message.
- If the message is **not** a response, store the `Session` object as an instance variable of the endpoint class in the method for handling a connection opened event. Storing the `Session` object in this way enables you to access it from other methods.

2. Use the `Session` object to obtain an object that implements one of the subinterfaces of `javax.websocket.RemoteEndpoint`.

- If you are sending the message synchronously, obtain a `RemoteEndpoint.Basic` object. This object provides blocking methods for sending a message.

To obtain a `RemoteEndpoint.Basic` object, invoke the `Session.getBasicRemote()` method.

- If you are sending the message asynchronously, obtain a `RemoteEndpoint.Async` object. This object provides non-blocking methods for sending a message.

To obtain a `RemoteEndpoint.Async` object, invoke the `Session.getAsyncRemote()` method.

3. Use the `RemoteEndpoint` object that you obtained in the previous step to send the message to the peer.

The following list shows some of the methods you can use to send a message to the peer:

- `void RemoteEndpoint.Basic.sendText(String text)`

Send a text message to the peer. This method blocks until the whole message has been transmitted.

- `void RemoteEndpoint.Basic.sendBinary(ByteBuffer data)`
Send a binary message to the peer. This method blocks until the whole message has been transmitted.
- `void RemoteEndpoint.sendPing(ByteBuffer appData)`
Send a ping frame to the peer.
- `void RemoteEndpoint.sendPong(ByteBuffer appData)`
Send a pong frame to the peer.

[Example 18–15](#) demonstrates how to use this procedure to reply to every incoming text message. For an example of how to send a message as the return value of a method, see [Example 18–8](#).

Example 18–15 Sending a Message to a Single Peer of an Endpoint

This example replies to every incoming text message by sending the message back to the peer of this endpoint.

```
import java.io.IOException;

import javax.websocket.OnMessage;
import javax.websocket.Session;
...
@OnMessage
public void onMessage(Session session, String msg) {
    try {
        session.getBasicRemote().sendText(msg);
    } catch (IOException e) { ... }
}
...
```

18.7.2 Sending a Message to All Peers of an Endpoint

Some WebSocket applications must send messages to all connected peers of the application's WebSocket endpoint, for example:

- A stock application must send stock prices to all connected clients.
- A chat application must send messages from one user to all other clients in the same chat room.
- An online auction application must send the latest bid to all bidders on an item.

However, each instance of an endpoint class is associated with one and only one connection and peer. Therefore, to send a message to all peers of an endpoint, you must iterate over the set of all open WebSocket sessions that represent connections to the same endpoint.

To send a message to all peers of an endpoint:

1. Obtain the set of all open WebSocket sessions that represent connections to the endpoint.
Invoke the `getOpenSessions` method on the endpoint's `Session` object for this purpose.
2. Send the message to each open session that you obtained in the previous step.
 - a. Use the session to obtain a `RemoteEndpoint` object.

- b. Use the `RemoteEndpoint` object to send the message.

For more information, see [Sending a Message to a Single Peer of an Endpoint](#).

Example 18–16 Sending a Message to All Peers of an Endpoint

This example forwards incoming text messages to all connected peers.

```
import java.io.IOException;

import javax.websocket.OnMessage;
import javax.websocket.Session;
import javax.websocket.server.ServerEndpoint;
...
@ServerEndpoint("/echoall")
public static class EchoAllEndpoint {
    @OnMessage
    public void messageReceived(Session session, String msg) {
        for (Session sess : session.getOpenSessions()) {
            try {
                sess.getBasicRemote().sendText(msg);
            } catch (IOException e) {
                // handle exception
            }
        }
    }
}
```

Ensuring Efficiency when Sending a Message to All Peers of an Endpoint

In a real-world application, in which many messages are being sent, you can use multiple threads to ensure that the application sends messages efficiently.

If too many WebSocket connections are open, using one thread to broadcast messages is inefficient, because the time it takes for a client to receive a message depends on its location in the iteration process. If thousands of WebSocket connections are open, then iteration is slow, causing some clients to receive messages early and other clients to receive messages much later. This delay is unacceptable in certain situations; for example, a stock application should ensure that each client receives stock price data as early as possible.

To increase efficiency, the application can partition open WebSocket connections into groups and then use multiple threads to broadcast messages to each group of WebSocket connections.

18.7.3 Ensuring Thread Safety for WebSocket Endpoints

The Java API for WebSocket specification requires that Java EE implementations instantiate endpoint classes once per connection. This requirement facilitates the development of WebSocket endpoints because you are guaranteed that only one thread is executing the code in a WebSocket endpoint class at any given time. When you introduce a new thread in an endpoint, you must ensure that variables and methods accessed by more than one thread are thread safe.

18.8 Encoding and Decoding a WebSocket Message

The Java API for WebSocket provides support for converting between WebSocket messages and custom Java types by using encoders and decoders. This mechanism

simplifies WebSocket applications because it decouples the business logic from the serialization and deserialization of objects.

An encoder takes a Java object and produces a representation that can be transmitted as a WebSocket text message or binary message. For example, encoders typically produce JavaScript Object Notation (JSON), Extensible Markup Language (XML), or binary representations. A decoder performs the reverse function: it reads a WebSocket message and creates a Java object.

Note: If you want to send and receive multiple Java types as the same type of WebSocket message, define the types to extend a common class. For example, if you want to send and receive the Java types `MessageA` and `MessageB` as text messages, define the types to extend the common class `Message`.

Defining the types in this way enables you to implement a single decoder class for multiple types.

18.8.1 Encoding a Java Object as a WebSocket Message

You can have more than one encoder for text messages and more than one encoder for binary messages. Like endpoints, encoder instances are associated with one and only one WebSocket connection and peer. Therefore, only one thread is executing the code of an encoder instance at any given time.

To encode a Java object as a WebSocket message:

1. For each custom Java type that you want to send as a WebSocket message, implement the appropriate interface for the type of the WebSocket message:
 - For a text message, implement `javax.websocket.Encoder.Text<T>`.
 - For a binary message, implement `javax.websocket.Encoder.Binary<T>`.

These interfaces specify the `encode` method.

2. Specify that your endpoint will use your encoder implementations.
 - For an annotated endpoint, add the names of your encoder implementations to the `encoders` optional element of the `ServerEndpoint` annotation.
 - For a programmatic endpoint, pass a list of the names of your encoder implementations as a parameter of the `encoders` method of a `javax.websocket.server.ServerEndpointConfig.Builder` object.
3. Use the `sendObject(Object data)` method of the `RemoteEndpoint.Basic` or `RemoteEndpoint.Async` interfaces to send your objects as messages.

The container looks for an encoder that matches your type and uses it to convert the object to a WebSocket message.

The following examples show how to send the Java types `com.example.game.message.MessageA` and `com.example.game.message.MessageB` as text messages:

- [Example 18–17](#)
- [Example 18–18](#)
- [Example 18–19](#)

Example 18–17 Implementing an Encoder Interface

This example implements the `Encoder.Text<MessageA>` interface.

```
package com.example.game.encoder;

import javax.websocket.EncodeException;
import javax.websocket.Encoder;
import javax.websocket.EndpointConfig;

import com.example.game.message.MessageA;
...
public class MessageATextEncoder implements Encoder.Text<MessageA> {
    @Override
    public void init(EndpointConfig ec) { }
    @Override
    public void destroy() { }
    @Override
    public String encode(MessageA msgA) throws EncodeException {
        // Access msgA's properties and convert to JSON text...
        return msgAJsonString;
    }
    ...
}
```

The implementation of `Encoder.Text<MessageB>` is similar.

Example 18–18 Defining Encoders for an Annotated WebSocket Endpoint

This example defines the encoder classes `MessageATextEncoder.class` and `MessageBTextEncoder.class` for the WebSocket server endpoint `EncEndpoint`.

```
package com.example.game;

import javax.websocket.server.ServerEndpoint;

import com.example.game.encoder.MessageATextEncoder;
import com.example.game.encoder.MessageBTextEncoder;
...

@ServerEndpoint(
    value = "/myendpoint",
    encoders = { MessageATextEncoder.class, MessageBTextEncoder.class }
    ...
)
public class EncEndpoint { ... }
```

Example 18–19 Sending Java Objects Encoded as WebSocket Messages

This example uses the `sendObject` method to send `MessageA` and `MessageB` objects as WebSocket messages.

```
import javax.websocket.Session;
...
import com.example.game.message.MessageA;
import com.example.game.message.MessageB;
...
MessageA msgA = new MessageA(...);
MessageB msgB = new MessageB(...);
session.getBasicRemote.sendObject(msgA);
session.getBasicRemote.sendObject(msgB);
```

...

18.8.2 Decoding a WebSocket Message as a Java Object

Unlike encoders, you can have at most **one** decoder for binary messages and **one** decoder for text messages. Like endpoints, decoder instances are associated with one and only one WebSocket connection and peer, so only one thread is executing the code of a decoder instance at any given time.

To decode a WebSocket message as a Java object:

1. Implement the appropriate interface for the type of the WebSocket message:
 - For a text message, implement `javax.websocket.Decoder.Text<T>`.
 - For a binary message, implement `javax.websocket.Decoder.Binary<T>`.These interfaces specify the `willDecode` and `decode` methods.
2. Specify that your endpoint will use your decoder implementations.
 - For an annotated endpoint, add the names of your decoder implementations to the `decoders` optional element of the `ServerEndpoint` annotation.
 - For a programmatic endpoint, pass a list of the names of your decoder implementations as a parameter of the `decoders` method of a `javax.websocket.server.ServerEndpointConfig.Builder` object.
3. Ensure that the method in your endpoint for handling a message received event takes your custom Java type as a parameter.

For more information, see [Handling Life Cycle Events for a WebSocket Connection](#).

When the endpoint receives a message that can be decoded by one of the decoders you specified, the container calls the method that takes your custom Java type as a parameter if this method exists.

The following examples show how to decode WebSocket text messages as the Java types `com.example.game.message.MessageA` and `com.example.game.message.MessageB`:

- [Example 18–20](#)
- [Example 18–21](#)
- [Example 18–22](#)

These examples assume that the Java types `com.example.game.message.MessageA` and `com.example.game.message.MessageB` extend the `com.example.game.message.Message` class.

Example 18–20 Implementing a Decoder Interface

This example implements the `Decoder.Text<Message>` interface.

Because only one decoder for text messages is allowed for an endpoint, the implementation is a decoder for the `Message` superclass. This decoder is used for decoding the subclasses of `Message`.

```
package com.example.game.decoder;

import javax.websocket.DecodeException;
import javax.websocket.Decoder;
```

```

import javax.websocket.EndpointConfig;

import com.example.game.message.Message;
import com.example.game.message.MessageA;
import com.example.game.message.MessageB;
...

public class MessageTextDecoder implements Decoder.Text<Message> {
    @Override
    public void init(EndpointConfig ec) { }
    @Override
    public void destroy() { }
    @Override
    public Message decode(String string) throws DecodeException {
        // Read message...
        if ( /* message is an A message */ )
            return new MessageA(...);
        else if ( /* message is a B message */ )
            return new MessageB(...);
    }
    @Override
    public boolean willDecode(String string) {
        // Determine if the message can be converted into either a
        // MessageA object or a MessageB object...
        return canDecode;
    }
}

```

Example 18–21 Defining a Decoder for an Annotated WebSocket Endpoint

This example defines the decoder class `MessageTextDecoder.class` for the WebSocket server endpoint `EncEndpoint`.

For completeness, this example also includes the definitions of the encoder classes `MessageATextEncoder.class` and `MessageBTextEncoder.class` from [Example 18–18](#).

```

package com.example.game;

import javax.websocket.server.ServerEndpoint;

import com.example.game.encoder.MessageATextEncoder;
import com.example.game.encoder.MessageBTextEncoder;
import com.example.game.decoder.MessageTextDecoder;
...
@ServerEndpoint(
    value = "/myendpoint",
    encoders = { MessageATextEncoder.class, MessageBTextEncoder.class },
    decoders = { MessageTextDecoder.class }
)
public class EncEndpoint { ... }

```

Example 18–22 Receiving WebSocket Messages Encoded as Java Objects

This example defines the method `message` that receives `MessageA` objects and `MessageB` objects.

```

import javax.websocket.OnMessage;
import javax.websocket.Session;
...

```

```
import com.example.game.message.Message;
import com.example.game.message.MessageA;
import com.example.game.message.MessageB;
...
@OnMessage
public void message(Session session, Message msg) {
    if (msg instanceof MessageA) {
        // We received a MessageA object...
    } else if (msg instanceof MessageB) {
        // We received a MessageB object...
    }
}
```

18.9 Specifying a Part of an Endpoint Deployment URI as an Application Parameter

The `ServerEndpoint` annotation enables you to use a level 1 URI template to specify parts of an endpoint deployment URI as application parameters. A URI template describes a range of URIs through variable expansion. For more information about URI templates, see <http://tools.ietf.org/html/rfc6570>.

To specify a part of an endpoint deployment URI as an application parameter:

1. Set the value element of the `ServerEndpoint` annotation to the URI template that you want to use.

In the URI template, enclose each variable for expansion in a pair of braces.

2. Declare each variable for expansion as a parameter in a method for handling one of the following types of event:
 - Connection opened
 - Connection closed
 - Message received

The type of the parameter can be `String`, a primitive type, or a boxed version of them.

3. Annotate the declaration of the parameter with the `javax.websocket.server.PathParam` annotation.
4. Set the value element of the `PathParam` annotation to the name of the variable.
5. In the body of the method that takes the parameter, provide logic for expanding the variable.

Example 18–23 shows how to specify a part of an endpoint deployment URI as an application parameter.

Example 18–23 Specifying a Part of an Endpoint Deployment URI as an Application Parameter

This example specifies an endpoint deployment URI as a URI template that contains the variable `{room-name}`. The variable is expanded through the `roomName` parameter of the `open` method to determine which chat room the user wants to join.

```
import javax.websocket.EndpointConfig;
import javax.websocket.OnOpen;
import javax.websocket.Session;
import javax.websocket.server.PathParam;
```

```
import javax.websocket.server.ServerEndpoint;

@ServerEndpoint("/chatrooms/{room-name}")
public class ChatEndpoint {
    @OnOpen
    public void open(Session session,
                    EndpointConfig c,
                    @PathParam("room-name") String roomName) {
        // Add the client to the chat room of their choice ...
    }
    ...
}
```

Code in the body of the open method to expand the {room-name} variable is not shown in this example.

If the endpoint is deployed inside a web application called chatapp at a local Java EE server in port 8080, clients can connect to the endpoint using any of the following URIs:

```
http://localhost:8080/chatapp/chatrooms/currentnews
http://localhost:8080/chatapp/chatrooms/music
http://localhost:8080/chatapp/chatrooms/cars
http://localhost:8080/chatapp/chatrooms/technology
```

18.10 Maintaining Client State

Because the container creates an instance of the endpoint class for every connection, you can define and use instance variables to store client state information.

In addition, the `Session.getUserProperties` method provides a modifiable map to store user properties.

To store information common to all connected clients, you can use class (static) variables; however, you are responsible for ensuring thread-safe access to them.

[Example 18–24](#) shows how to maintain client state.

Example 18–24 *Maintaining Client State*

This example replies to incoming text messages with the contents of the previous message from each client.

```
import java.io.IOException;
import javax.websocket.OnMessage;
import javax.websocket.OnOpen;
import javax.websocket.Session;
import javax.websocket.server.ServerEndpoint;

@ServerEndpoint("/delayedecho")
public class DelayedEchoEndpoint {
    @OnOpen
    public void open(Session session) {
        session.getUserProperties().put("previousMsg", " ");
    }
    @OnMessage
    public void message(Session session, String msg) {
        String prev = (String) session.getUserProperties()
            .get("previousMsg");
        session.getUserProperties().put("previousMsg", msg);
    }
}
```

```

    try {
        session.getBasicRemote().sendText(prev);
    } catch (IOException e) { ... }
}
}

```

18.11 Configuring a Server Endpoint Programmatically

The Java API for WebSocket enables you to configure how the container creates server endpoint instances. You can provide custom endpoint configuration logic for:

- Accessing the details of the handshake request for a WebSocket connection
- Performing custom checks on the Origin HTTP header
- Modifying the WebSocket handshake response
- Choosing a WebSocket subprotocol from those requested by the client
- Controlling the instantiation and initialization of endpoint instances
- Specifying the extensions that a server endpoint will support

To configure a server endpoint programmatically:

1. Extend the `javax.websocket.server.ServerEndpointConfig.Configurator` class.
2. Override the methods that perform the configuration operations for which you require custom logic, as shown in the following table.

Configuration Operation	Method to Override
Accessing the details of the handshake request for a WebSocket connection	<code>modifyHandshake</code>
Performing custom checks on the Origin HTTP header	<code>checkOrigin</code>
Modifying the WebSocket handshake response	<code>modifyHandshake</code>
Choosing a WebSocket subprotocol from those requested by the client	<code>getNegotiatedSubprotocol</code>
Controlling the instantiation and initialization of endpoint instances	<code>getEndpointInstance</code>
Specifying the extensions that a server endpoint will support	<code>getNegotiatedExtensions</code>

3. In the server endpoint class, set the `configurator` element of the `ServerEndpoint` annotation to the configurator class.

The following examples show how to configure a server endpoint programmatically:

- [Example 18–25](#)
- [Example 18–26](#)

Example 18–25 Extending the `ServerEndpointConfig.Configurator` Class

This example extends the `ServerEndpointConfig.Configurator` class to make the handshake request object available to endpoint instances.

```

import javax.websocket.HandshakeResponse;
import javax.websocket.server.ServerEndpointConfig.Configurator;
import javax.websocket.server.HandshakeRequest;

```

```

...
public class CustomConfigurator extends ServerEndpointConfig.Configurator {

    @Override
    public void modifyHandshake(ServerEndpointConfig conf,
                               HandshakeRequest req,
                               HandshakeResponse resp) {

        conf.getUserProperties().put("handshakereq", req);
    }
    ...
}

```

Example 18–26 Specifying a Custom Configurator for a Server Endpoint Class

This example specifies the custom configurator class `CustomConfigurator.class` for the server endpoint class `MyEndpoint`.

The custom configurator enables instances of the server endpoint class to access the handshake request object. The server endpoint class uses the handshake request object to access the details of the handshake request, such as its headers or the `HttpSession` object.

```

import javax.websocket.EndpointConfig;
import javax.websocket.HandshakeResponse;
import javax.websocket.OnOpen;
import javax.websocket.Session;
import javax.websocket.server.HandshakeRequest;
import javax.websocket.server.ServerEndpoint;
import java.util.List;
import java.util.Map;
...
@ServerEndpoint(
    value = "/myendpoint",
    configurator = CustomConfigurator.class
)
public class MyEndpoint {

    @OnOpen
    public void open(Session s, EndpointConfig conf) {
        HandshakeRequest req = (HandshakeRequest) conf.getUserProperties()
            .get("handshakereq");
        Map<String, List<String>> headers = req.getHeaders();
        ...
    }
}

```

18.12 Building Applications that Use the Java API for WebSocket

WebLogic Server provides the Java API for WebSocket within the `wlserver/server/lib/api.jar` file. To build applications that use the Java API for WebSocket, define this library in the classpath when compiling the application.

You can also use Maven to build applications that use the Java API for WebSocket. If you are using Maven, obtain the Maven artifact that contains the Java API for WebSocket from maven central as `javax.websocket:javax.websocket-api:1.1`. For more information, see ["Using the WebLogic Maven Plug-In"](#).

18.13 Deploying a WebSocket Application

In WebLogic Server, you deploy a WebSocket application as part of a standard Java EE Web application archive (WAR), either as a standalone Web application or a WAR module within an enterprise application.

You do not need to configure the WebSocket endpoint in the `web.xml` file, or any other deployment descriptor, or perform any type of dynamic operation to register or enable the WebSocket endpoint.

However, you can optionally set the context initialization properties that are listed in [Table 18–3](#). To indicate that these properties are specific to WebLogic Server and not part of the JSR 356 specification, their fully qualified names contain the prefix `weblogic.websocket`.

Table 18–3 Context Initialization Properties for a WebSocket Application

Property	Type	Description
<code>weblogic.websocket.tyrus.incoming-buffer-size</code>	Integer	<p>The maximum underlying buffer size in bytes for receiving messages. The application cannot process messages that are larger than this size.</p> <p>This parameter affects the following server sessions and client sessions:</p> <ul style="list-style-type: none"> ■ All server sessions in the same application ■ Only client sessions that are connected with the server-instantiated <code>javax.websocket.server.ServerContainer</code> object in the application <p>You can override this setting for clients sessions by setting a property of the same name for a client endpoint. For more information, see Configuring a WebSocket Client Endpoint Programmatically.</p> <p>The default buffer size is 4194315, of which 4 Mbytes are for the payload and 11 bytes are for the frame overhead.</p>
<code>weblogic.websocket.tyrus.session-max-idle-timeout</code>	Integer	<p>The maximum period in milliseconds after which an idle connection times out. The default value is 30000, which corresponds to 30 seconds.</p>

[Example 18–27](#) shows how to set context initialization properties for a WebSocket application.

Example 18–27 Setting Context Initialization Properties for a WebSocket Application

This example sets context initialization parameters for a WebSocket application as follows:

- The maximum underlying buffer size for receiving messages is set to 16777227 bytes.
- The maximum period after which an idle connection times out is set to 60,000 milliseconds, which corresponds to 1 minute.

```
<?xml version="1.1" encoding="UTF-8"?>
<web-app version="3.0" ...>
```

```

...
<context-param>
  <param-name>weblogic.websocket.tyrus.incoming-buffer-size</param-name>
  <param-value>16777227</param-value>
</context-param>
<context-param>
  <param-name>weblogic.websocket.tyrus.session-max-idle-timeout</param-name>
  <param-value>60000</param-value>
</context-param>
</web-app>

```

18.14 Monitoring WebSocket Applications

You can monitor message statistics and runtime properties for WebSocket applications and endpoints. Endpoint-level monitoring collects information per individual endpoint, while application-level monitoring aggregates information from all endpoints deploying in the given application.

[Table 18–4](#) details the types of properties monitored at runtime and whether monitoring occurs at the application or endpoint level. For message-related properties, WebLogic Server uses bytes for message size and distinguishes three types of messages: text, binary, and control.

Table 18–4 *WebSocket Monitoring Properties*

Property	Description	Monitoring Level
Open session count	The number of current open sessions for the WebSocket application or endpoint.	application, endpoint
Maximum open sessions count	The highest number of open sessions for the WebSocket application or endpoint since server startup.	application, endpoint
Error counts	The list of errors with the number of times each error has occurred. Errors are represented by throwable class names.	application, endpoint
Sent messages count	The number of sent messages for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Received messages count	The number of received messages for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Sent messages count per second	The number of sent messages per second for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint

Table 18–4 (Cont.) WebSocket Monitoring Properties

Property	Description	Monitoring Level
Received messages count per second	The number of received messages per second for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Minimum sent message size	The smallest sent message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Minimum received message size	The smallest received message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Maximum sent message size	The largest sent message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Maximum received message size	The largest received message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Average sent message size	The average sent message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Average received message size	The average received message size for the WebSocket application or endpoint since monitoring began. Statistics are provided per individual message type (text, binary, and control) and as a total count.	application, endpoint
Endpoint path	The path on which the endpoint is registered, relative to the application context root.	endpoint only
Endpoint class name	The name of the endpoint class.	endpoint only

To access monitored metrics for WebSocket applications and endpoints at runtime, use the following MBeans:

- `WebAppComponentRuntimeMBean`
- `WebSocketApplicationRuntimeMBean`

- `WebsocketBaseRuntimeMBean`
- `WebsocketEndpointRuntimeMBean`
- `WebsocketMessageStatisticsRuntimeMBean`

To use the Administration Console or Fusion Middleware Control to monitor WebSocket applications and endpoints, see the following online help topics:

- "Monitoring WebSocket applications" in *Oracle WebLogic Server Administration Console Online Help*
- "Monitor a WebSocket application" in *Administering Oracle WebLogic Server with Fusion Middleware Control*

18.15 Using WebSockets with Proxy Servers

Clients accessing WebSocket applications must either connect directly to the WebLogic Server instance or through a Web proxy server that supports the WebSocket protocol.

The following proxy servers support the WebSocket protocol:

- Oracle Traffic Director
- Oracle HTTP Server starting from release 12.1.3
- Apache 2.2 or 2.4 when used with Oracle WebLogic WebServer Plugin (12.1.2.0.0)

18.16 Writing a WebSocket Client

A WebSocket client application is typically a browser-based client. The Java API for WebSocket can also be used to write a Java WebSocket client.

18.16.1 Writing a Browser-Based WebSocket Client

A browser-based WebSocket client application is typically a composite of HTML5 technologies, including HTML markup, CSS3, and JavaScript that makes use of the WebSocket JavaScript API. For more information about HTML5, see <http://www.w3.org/TR/html5/>.

Most browsers support the W3C WebSocket API that can be used to create and work with the WebSocket protocol. For information about the W3C WebSocket API, see: <http://www.w3.org/TR/websockets/>.

If the WebSocket protocol is not guaranteed to be supported in the runtime environment, use the JavaScript API for WebSocket fallback in your browser-based client. This API provides an implementation of the standard W3C WebSocket API. The API also provides a mechanism for using an alternative transport for WebSocket messaging when the WebSocket protocol is not supported. For more information, see [Enabling Protocol Fallback for WebSocket Messaging](#).

The following steps show an example of the execution flow on a client that is sending messages to a WebLogic Server instance using the WebSockets Protocol.

1. The client opens a WebSocket connection to the server hosting the WebSocket endpoint, using the `ws://` or `wss://` protocol prefix. For more information, see ["Establishing Secure WebSocket Connections"](#).

```
var url = ((window.location.protocol == "https:") ? "wss:" : "ws:")
+ "://" + window.location.host
+ "/websocket-helloworld-wls/helloworld_delay.ws";
```

```
var ws = new WebSocket(url);
```

2. The client registers listeners with the WebSocket object to respond to events, such as opening, closing, and receiving messages. Based on the event and the information received, the client performs the appropriate action.

```
ws.onopen = function(event) {
    document.getElementById("status").innerHTML = "OPEN"
}
```

```
ws.onmessage = function(event) {
    msg = event.data
    document.getElementById("short_msg").innerHTML =
        event.data;
}
```

3. The client sends messages to the server over the WebSocket object as needed by the application.

```
function sendMsg() {
    // Check if connection is open before sending
    if(ws == null || ws.readyState != 1) {
        document.getElementById("reason").innerHTML
            = "Not connected can't send msg"
    } else {
        ws.send(document.getElementById("name").value);
    }
}
```

```
<input id="send_button" class="button" type="button" value="send"
onclick="sendMsg()" />
```

18.16.2 Writing a Java WebSocket Client

The `javax.websocket` package contains annotations, classes, interfaces, and exceptions that are common to client and server endpoints. Use the APIs in this package for writing a Java WebSocket client in the same way as for writing a server. Additional programming tasks that are specific to writing a client are described in the subsections that follow.

18.16.2.1 Configuring a WebSocket Client Endpoint Programmatically

WebLogic Server provides properties for configuring how the container creates client endpoint instances. To indicate that these properties are specific to WebLogic Server and not part of the JSR 356 specification, their fully qualified names contain the prefix `weblogic.websocket`.

WebLogic Server provides properties for the following:

- **HTTP proxy configuration.** WebLogic Server supports client connections to a remote server WebSocket endpoint through an HTTP proxy as defined in the WebSocket Protocol (RFC 6455).

Properties for HTTP proxy configuration are listed in [Table 18–5](#).

- **Secure Sockets Layer (SSL) configuration.** WebLogic Server supports client connections to a remote server WebSocket endpoint over SSL with `wss` scheme.

Properties for SSL configuration are listed in [Table 18–6](#).

- **Buffer size for incoming messages.** WebLogic Server supports limiting the size of incoming messages for WebSocket client endpoints.

Properties for buffer size configuration are described in [Table 18–7](#).

Table 18–5 HTTP Proxy Configuration Properties for a Java WebSocket Client

Property	Type	Description
<code>weblogic.websocket.client.PROXY_HOST</code>	String	The name of the HTTP proxy host. If you are configuring proxy settings for a JavaScript client, you must specify this property.
<code>weblogic.websocket.client.PROXY_PORT</code>	Integer	Optional. The port number for connections to the HTTP proxy host. If you specify an HTTP proxy host without the port number, the port number defaults to 80.
<code>weblogic.websocket.client.PROXY_USERNAME</code>	String	Optional. The user name for logging in to the proxy host.
<code>weblogic.websocket.client.PROXY_PASSWORD</code>	String	Optional. The user name for logging in to the proxy host.

Table 18–6 SSL Configuration Properties for a Java WebSocket Client

Property	Type	Description
<code>weblogic.websocket.client.SSL_PROTOCOLS</code>	String	Optional. A comma-separated list of supported versions of the SSL protocol.
<code>weblogic.websocket.client.SSL_TRUSTSTORE</code>	String	Optional. The path to the keystore file, which contains the security certificates for use in SSL encryption.
<code>weblogic.websocket.client.SSL_TRUSTSTORE_PWD</code>	String	Optional. The password for the keystore.

Table 18–7 Buffer-Size Configuration Properties for a Java WebSocket Client

Property	Type	Description
<code>weblogic.websocket.tyrus.incoming-buffer-size</code>	Integer	The maximum underlying buffer size in bytes for receiving messages. The client cannot process messages that are larger than this size. If set, this property overrides the value of the context initialization property of the same name that is described in Table 18–3 . The default buffer size is 4194315, of which 4 Mbytes are for the payload and 11 bytes are for the frame overhead.

Note: Configure a client endpoint before connecting the client to its server endpoint.

To configure a WebSocket client endpoint programmatically:

1. Obtain a `javax.websocket.ClientEndpointConfig` object.
 - a. Invoke the `javax.websocket.ClientEndpointConfig.Builder.create` static method to obtain an instance of the `ClientEndpointConfig.Builder` class.
 - b. Invoke the `build` method on the `ClientEndpointConfig.Builder` object that you obtained in the previous step.
2. Set each configuration property that you want to change to its new value.

- a. Invoke the `getUserProperties` method on the `ClientEndpointConfig` object that you obtained in the previous step to obtain a modifiable `java.util.Map` object that contains the user properties.
- b. Invoke the `put` method on the `Map` object that you obtained in the previous step.

In the invocation of the `put` method, provide the property name and its new value as parameters to the method.

[Example 18–28](#) shows how to configure a WebSocket client endpoint programmatically.

Example 18–28 Configuring a WebSocket Client Endpoint Programmatically

This example programmatically configures a WebSocket client endpoint as follows:

- The name of the HTTP proxy host is set to `proxy.example.com`.
- The port number for connections to the HTTP proxy host is set to 80.
- The path to the keystore file is set to `/export/keystore`.
- The password for the keystore is set to `changeit`.
- The maximum underlying buffer size for receiving messages is set to 16777227 bytes, that is 16 Mbytes for the payload and 11 bytes for the frame overhead.

```
...
import javax.websocket.ClientEndpointConfig;
...
ClientEndpointConfig cec = ClientEndpointConfig.Builder.create().build();
// configure the proxy host
cec.getUserProperties().put("weblogic.websocket.client.PROXY_HOST",
    "proxy.example.com");

// configure the proxy port
cec.getUserProperties().put("weblogic.websocket.client.PROXY_PORT", 80);
// configure the trust keystore path
cec.getUserProperties().put("weblogic.websocket.client.SSL_TRUSTSTORE",
    "/export/keystore");

// configure the trust keystore's password
cec.getUserProperties().put("weblogic.websocket.client.SSL_TRUSTSTORE_PWD",
    "changeit");

// for receiving 16 Mbyte payload
cec.getUserProperties().put("weblogic.websocket.tyrus.incoming-buffer-size",
    16 * 1024 * 1024 + 11);
...

```

18.16.2.2 Connecting a Java WebSocket Client to a Server Endpoint

To connect a Java WebSocket client to a server endpoint:

1. Invoke the `javax.websocket.ContainerProvider.getWebSocketContainer()` static method to obtain the client's `javax.websocket.WebSocketContainer` instance.
2. Invoke the overloaded `connectToServer` method on the `WebSocketContainer` object that you obtained in the previous step.

The variant of the method to invoke depends on whether the endpoint is an annotated endpoint or a programmatic endpoint and whether support for Java EE services such as dependency injection are required.

Endpoint Type	Support for Java EE Services	Variant of the connectToServer Method
Annotated	Not required	<code>connectToServer(Object annotatedEndpointInstance, URI path)</code>
Annotated	Required	<code>connectToServer(Class<?> annotatedEndpointClass, URI path)</code>
Programmatic	Not required	<code>connectToServer(Endpoint endpointInstance, ClientEndpointConfig cec, URI path)</code>
Programmatic	Required	<code>connectToServer(Class<? extends Endpoint> endpointClass, ClientEndpointConfig cec, URI path)</code>

In the invocation of the `connectToServer` method, provide the following information as parameters to the method:

- The **client** WebSocket endpoint
- The complete path to the **server** WebSocket endpoint

If the **client** endpoint is a programmatic endpoint, you must also provide configuration information for the endpoint.

[Example 18–29](#) shows how to connect a Java WebSocket client to a server endpoint.

Example 18–29 Connecting a Java WebSocket Client to a Server Endpoint

This example connects the Java WebSocket client `ClientExample` to the WebSocket server endpoint at `ws://example.com:80/echoserver/echo`. The WebSocket client endpoint is represented by the class `ExampleEndpoint`. The declaration of the `ExampleEndpoint` class is shown in [Example 18–4](#).

```
import java.io.IOException;
import java.net.URI;

import javax.websocket.CloseReason;
import javax.websocket.ContainerProvider;
import javax.websocket.Session;
import javax.websocket.WebSocketContainer;
...

public class ClientExample {

    public static void main(String[] args) throws Exception {
        WebSocketContainer container = ContainerProvider.getWebSocketContainer();
        Session session = container.connectToServer(ExampleEndpoint.class,
            new URI("ws://example.com:80/echoserver/echo"));
        ...
        session.close();
    }
}
```

18.16.2.3 Setting the Maximum Number of Threads for Dispatching Messages from a WebSocket Client

By default, the maximum number of threads for dispatching messages from a WebSocket client depends on how many processors are available:

- If 20 or fewer processors are available, the maximum number of threads is 20.
- If more than 20 processors are available, the maximum number of threads is equal to the number of available processors.

To set the maximum number of threads for dispatching messages from a WebSocket client:

1. In the `java` command to launch your client application, set the system property `weblogic.websocket.client.max-aio-threads` to the number that you require.

[Example 18–30](#) shows how to set the maximum number of threads for dispatching messages from a WebSocket client.

Example 18–30 Setting the Maximum Number of Threads for Dispatching Messages from a WebSocket Client

This example sets the maximum number of threads for dispatching messages from the WebSocket client `ClientExample` to 50.

```
java -Dweblogic.websocket.client.max-aio-threads=50 ClientExample
```

18.17 Securing a WebSocket Application

In WebLogic Server, you deploy a WebSocket application as a Web application archive (WAR), either as a standalone Web application or a WAR module within an enterprise application. Therefore, many security practices that you apply to securing Web applications can apply to WebSocket applications. For information about Web application security, see "Developing Secure Web Applications" in *Developing Applications with the WebLogic Security Service*.

The following sections describe security considerations for WebSocket applications in WebLogic Server:

- [Applying Verified-Origin Policies](#)
- [Authenticating and Authorizing WebSocket Clients](#)
- [Establishing Secure WebSocket Connections](#)
- [Avoiding Mixed Content](#)

18.17.1 Applying Verified-Origin Policies

Modern browsers use same-origin policies to prevent scripts that are running on Web pages loaded from one origin from interacting with resources from a different origin. The WebSocket Protocol (RFC 6455) uses a verified-origin policy that enables the server to decide whether or not to consent to a cross-origin connection.

When a script sends an opening handshake request to a WebSocket application, an `Origin` HTTP header is sent with the WebSocket handshake request. If the application does not verify the `Origin`, then it accepts connections from any origin. If the application is configured not to accept connections from origins other than the expected origin, then the WebSocket application can reject the connection.

You can ensure that the WebSocket application verifies the `Origin` by extending the `javax.websocket.server.ServerEndpointConfig.Configurator` class.

The following code example demonstrates applying a verified-origin policy:

```
...  
import javax.websocket.server.ServerEndpointConfig;
```

```

public class MyConfigurator extends ServerEndpointConfig.Configurator {
    ...
    private static final String ORIGIN = "http://www.example.com:7001";

    @Override
    public boolean checkOrigin(String originHeaderValue) {
        return ORIGIN.equals(originHeaderValue)
    }
}
...

```

For more information, see [Configuring a Server Endpoint Programmatically](#).

Note: Nonbrowser clients (for example, Java clients) are not required to send an `Origin` HTTP header with the WebSocket handshake request. If a WebSocket handshake request does not include an `Origin` header, then the request is from a nonbrowser client; if a handshake request includes an `Origin` header, then the request may be from either a browser or a nonbrowser client.

Because nonbrowser clients can send arbitrary `Origin` headers, the browser origin security model is not recommended for nonbrowser clients.

18.17.2 Authenticating and Authorizing WebSocket Clients

The WebSocket Protocol (RFC 6455) does not specify an authentication method for WebSocket clients during the handshake process. You can use standard Web container authentication and authorization functionality to prevent unauthorized clients from opening WebSocket connections on the server.

All configurations of the `<auth-method>` element that are supported for Web applications can also be used for WebSocket applications. These authentication types include BASIC, FORM, CLIENT-CERT, and so on. For more information, see "Developing Secure Web Applications" in *Developing Applications with the WebLogic Security Service*.

You can secure the path to the endpoint within your application by configuring the relevant `<security-constraint>` element in the `web.xml` deployment descriptor file of the WebSocket application. By configuring `<security-constraint>`, clients must authenticate themselves before sending WebSocket handshake requests. Otherwise, the server rejects the WebSocket handshake request. For more information about the `<security-constraint>` element, see "web.xml Deployment Descriptor Elements" in *Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server*.

The following code example demonstrates securing the path to the endpoint within your application, where the path is `/demo`:

```

<security-constraint>
  <web-resource-collection>
    <web-resource-name>Secured WebSocket Endpoint</web-resource-name>
    <url-pattern>/demo</url-pattern>
    <http-method>GET</http-method>
  </web-resource-collection>
  <auth-constraint>
    <role-name>user</role-name>
  </auth-constraint>
</security-constraint>

```

```
<login-config>
  <auth-method>FORM</auth-method>
  <form-login-config>
    <form-login-page>/login.jsp</form-login-page>
    <form-error-page>/error.jsp</form-error-page>
  </form-login-config>
</login-config>
<security-role>
  <role-name>user</role-name>
</security-role>
```

18.17.2.1 Authorizing WebSocket Clients

You can configure a WebSocket application to implement BASIC and DIGEST authentication methods and authorize certain clients by manipulating handshake message headers through the `javax.websocket.ClientEndpointConfig.Configurator` class. If the application does not authorize a client to create a WebSocket connection, the server rejects the WebSocket handshake request from that client.

To check the value of the origin header that the client passed during the opening handshake, use the `checkOrigin` method of the `javax.websocket.server.ServerEndpointConfig.Configurator` class. To provide custom checks, you can override this method. For more information, see [Configuring a Server Endpoint Programmatically](#).

18.17.3 Establishing Secure WebSocket Connections

To establish a WebSocket connection, the client sends a handshake request to the server. When using the `ws` scheme to open the WebSocket connection, the handshake request is a plain HTTP request; the data being transferred over the established WebSocket connection is not encrypted.

To establish a secure WebSocket connection and prevent data from being intercepted, WebSocket applications should use the `wss` scheme. The `wss` scheme ensures that clients send handshake requests as HTTPS requests, encrypting transferred data by TLS/SSL.

You can configure a WebSocket application to accept only HTTPS handshake requests, where all WebSocket connections must be encrypted and unencrypted WebSocket handshake requests are rejected. Specify the `<user-data-constraint>` element in the `web.xml` deployment descriptor file of the WebSocket application. For more information about the `<user-data-constraint>` element, see "web.xml Deployment Descriptor Elements" in *Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server*.

The following code example demonstrates configuring the `<user-data-constraint>` element:

```
<security-constraint>
  <web-resource-collection>
    <web-resource-name>Secured WebSocket Endpoint</web-resource-name>
    <url-pattern>/demo</url-pattern>
    <http-method>GET</http-method>
  </web-resource-collection>
  <auth-constraint>
    <role-name>user</role-name>
  </auth-constraint>
  <user-data-constraint>
    <transport-guarantee>CONFIDENTIAL</transport-guarantee>
```

```
</user-data-constraint>  
</security-constraint>
```

18.17.4 Avoiding Mixed Content

If a script attempts to open a WebSockets connection through the `ws://` URI (using a plain HTTP request), but the top-level Web page is retrieved through an HTTPS request, the Web page is referred to as mixed content. Although most browsers no longer allow mixed content, some still do. WebSocket applications should avoid mixed content, because it allows certain information that should be protected, such as JSESSIONID and cookies, to be exposed.

For more information about mixed content, see "Web Security Context: User Interface Guidelines" at <http://www.w3.org/TR/wsc-ui/#securepage>.

18.17.5 Specifying Limits for a WebSocket Connection

By specifying limits for a WebSocket connection, you can prevent clients from exhausting server resources, such as memory, sockets, and so forth.

You can specify the following limits for a WebSocket connection:

- **Maximum message size.** To set the maximum message size for a WebSocket connection, set the `maxMessageSize` element of the `onMessage` annotation to the size in bytes.
- **Idle timeout value.** To set the idle timeout value for a WebSocket connection, invoke one of the following methods:
 - For an individual connection, invoke the `setMaxIdleTimeout` method of the `Session` object.
 - For the entire container, invoke the `setDefaultMaxSessionIdleTimeout` method of a `WebSocketContainer` object.

18.18 Enabling Protocol Fallback for WebSocket Messaging

Protocol fallback provides a mechanism for using an alternative transport for WebSocket messaging when the WebSocket protocol is not supported. Typically the WebSocket protocol is not supported either because the WebSocket object is not available or because WebSocket frames are blocked by a firewall. In this release, the only supported alternative transport is HTTP Long Polling.

Protocol fallback enables you to rely on standard programming APIs to perform WebSocket messaging regardless of whether or not the runtime environment supports the WebSocket protocol.

Note: To support WebSocket fallback, the server must use the JSR 356 Java API for WebSocket, not the proprietary WebLogic Server WebSocket API.

18.18.1 Using the JavaScript API for WebSocket Fallback in Client Applications

The JavaScript API for WebSocket fallback provides an implementation of the standard W3C WebSocket API and additional APIs to facilitate WebSocket fallback. For information about the JavaScript API for WebSocket fallback, see *JavaScript API Reference for WebSocket Fallback*. For information about the W3C WebSocket API, see: <http://www.w3.org/TR/websockets/>.

When you use the standard W3C WebSocket JavaScript API, code your application without regard to whether the WebSocket protocol is supported.

18.18.1.1 Configuring WebSocket Fallback

WebLogic Server provides properties for configuring WebSocket fallback as listed in [Table 18–8](#).

Table 18–8 *WebSocket Fallback Configuration Properties*

Property	Type	Default	Description
baseUrl	string	.	The location of the <code>scripts</code> directory, relative to the HTML context of the page. The structure of the <code>scripts</code> directory must be preserved. The <code>scripts</code> directory can be moved to wherever it can be reached, but its content must not change after it was created.
debug	integer	0	The debug level.
ENCODE_FOR_IE_BELOW	integer	10	The version of the Internet Explorer browser below which Base16 encoding is to be used for framed data.
ENFORCE_ENCODING	Boolean	false	Whether Base16 encoding is to be used.
NB_TRY_FOR_EACH_TRANSPORT	integer	2	The maximum number of consecutive retries to establish a connection on a given transport.
PING_INTERVAL	integer	25000	Interval in milliseconds between consecutive pings to the server.
SERVER_PING_ENABLED	Boolean	true	Whether pings from the client to the server are enabled.
transport	string	none	The enforced transport, which can be one of the following transports: <ul style="list-style-type: none"> ■ WebSocket ■ XMLHttpRequest
TRY_AGAIN_INTERVAL	integer	1000	The number of seconds after which an unsuccessful connection attempt is repeated with the same transport. The retry count for the transport is not incremented. If the attempt fails within this number of milliseconds, the retry count is incremented by 1.
WEBSOCKET_CREATION_TIMEOUT	integer	1000	The number of milliseconds after which creation of a WebSocket connection is considered to have failed.

If the WebSocket protocol is available, WebLogic Server uses that protocol even if protocol fallback is enabled. WebLogic Server uses the value of the `TRY_AGAIN_INTERVAL` property and the `NB_TRY_FOR_EACH_TRANSPORT` property as follows to determine whether the WebSocket protocol is available if a connection attempt fails:

- If the connection is not established within `TRY_AGAIN_INTERVAL` milliseconds, the attempt is repeated with same transport. The retry count for this transport is **not** incremented.
- If the attempt fails within `TRY_AGAIN_INTERVAL` milliseconds, the retry count is incremented by 1.
- If the retry count reaches the value of `NB_TRY_FOR_EACH_TRANSPORT`, the next transport is tried.
- If the retry count for the last transport reaches the value of `NB_TRY_FOR_EACH_TRANSPORT`, the connection is closed, that is, the `onClose` function is called on the client.

To configure WebSocket fallback:

1. Construct a JSON object in which you set the configuration properties that you require.

For details about these properties, see [Table 18–8](#).

2. Pass the object as a parameter to one of the following functions:

- If the fallback mechanism cannot be guaranteed to be present, pass the object as the parameter to the `OraSocket.configure` function **before** constructing the WebSocket object.

To ensure that your application does not fail if the JavaScript library for WebSocket fallback is unavailable, call the `OraSocket.configure` function in a `try/catch` block.

- Otherwise, pass the object as the second, optional parameter of the WebSocket object's constructor.

[Example 18–31](#) shows how to configure WebSocket fallback.

Example 18–31 Configuring WebSocket Fallback

This example enforces the `XMLHttpRequest` transport, sets the debug level to 10, and disables pings from the client to the server.

```
...
    try {
        var config = {};
        config = { transport: XMLHttpRequest, debug: 10, SERVER_PING_ENABLED: false
    };
    OraSocket.config(config);
    } catch (err) {
        console.log("Error creating WebSocket:" + JSON.stringify(err));
    }
...

```

18.18.1.2 Creating a WebSocket Object

A WebSocket object represents a WebSocket connection from the client to a remote host.

To create a WebSocket object, invoke the `WebSocket` constructor, passing the following information as parameters:

- The URL to which the client should connect
- Optionally, a JSON object that contains configuration settings for WebSocket fallback

For more information about the JSON object, see [Configuring WebSocket Fallback](#).

[Example 18–32](#) shows how to create a WebSocket object.

Example 18–32 Creating a WebSocket Object

This example creates the WebSocket Object `ws`. The example uses standard JavaScript functions to determine the URL to which the client should connect from the URL of the document that contains this code.

```
...
var URI_SUFFIX = "/websocket-101/ws-101-app";
var ws;

```

```

var connectionStatus = "Connecting...";
var calledBy = document.location.toString();
var machine, port, secured;
var regExp = new RegExp("(http|ws)(.?):[/]{2}([^\|/]*):?(\\d*)/(.*)");
var matches = regExp.exec(calledBy);
secured = matches[2];
machine = matches[3];
port    = matches[4];
...
statusFld = document.getElementById('status');
...
try
{
    var wsURI = "ws" + secured + "://" + machine + ":" + port + URI_SUFFIX;
    ws = new WebSocket(wsURI);
}
catch (err)
{
    var mess = 'WebSocket creation error:' + JSON.stringify(err);
    connectionStatus = "<font color='red'>Unable to connect.</font>";
    if (statusFld !== undefined)
        statusFld.innerHTML = mess;
    else
        alert(mess);
}
...

```

18.18.1.3 Handling Life Cycle Events for a JavaScript WebSocket Client

Handling lifecycle events for a JavaScript WebSocket client involves writing the WebSocket object's callback functions as listed in [Table 18-9](#). The table also provides a cross-reference to an example that shows how to handle each type of event.

Table 18-9 *Callback Functions for Handling Life Cycle Events*

Event	Callback Function	Example
Connection opened	onopen	Example 18-33
Message received	onmessage	Example 18-34
Error	onerror	Example 18-35
Connection closed	onclose	Example 18-36

Note: The creation of the ws WebSocket object in the examples is shown in [Example 18-32](#).

Example 18-33 *Handling a Connection Opened Event for a JavaScript WebSocket Client*

This example uses standard JavaScript functions to display the current date and time followed by the message Connection opened when a connection is opened.

```

...
ws.onopen = function()
{
    try
    {
        var text;
        try
        {

```

```

        text = 'Message: ';
    }
    catch (err)
    {
        text = '<small>Connected</small>';
    }
    promptFld.innerHTML = text;
    if (nbMessReceived === 0)
        statusFld.innerHTML = "";
    statusFld.innerHTML += ((nbMessReceived === 0?"": "<br>") + "<small>" +
        (new Date()).format("d-M-Y H:i:s_ Z") +
        "</small>:<font color='blue'>" +
        ' Connection opened.' + "</font>");
    statusFld.scrollTop = statusFld.scrollHeight;
    nbMessReceived++;
}
catch (err) {}
};
...

```

Example 18–34 Handling a Message Received Event for a JavaScript WebSocket Client

This example uses standard JavaScript functions to display the current time followed by the content of the message when a message is received.

```

...
ws.onmessage = function(message) // message/event
{
    var json = {};
    if (typeof(message.data) === 'string')
    {
        try
        {
            json = JSON.parse(message.data);
        }
        catch (e)
        {
            console.log(e);
            console.log('This doesn\'t look like valid JSON: ' + message.data);
        }
    }
    if (json.type !== undefined && json.type === 'message' &&
        typeof(json.appdata.text) === 'string') // it's a single message, text
    {
        var dt = new Date();
        /**
         * Add message to the chat window
         */
        var existing = contentFld.innerHTML; // Content already there
        var toDisplay = "";
        try { toDisplay = json.appdata.text; }
        catch (err) {}
        contentFld.innerHTML = existing +
            ('At ' +
            + (dt.getHours() < 10 ? '0' + dt.getHours() : dt.getHours()) + ':' +
            + (dt.getMinutes() < 10 ? '0' + dt.getMinutes() : dt.getMinutes())
            + ': ' + toDisplay + '<br>');
        contentFld.scrollTop = contentFld.scrollHeight;
    }
    else // Unexpected

```

```

    {
      var payload = {};
    }
  };
  ...

```

Example 18–35 Handling an Error Event for a JavaScript WebSocket Client

This example uses standard JavaScript functions to display the current date and time followed by an error message when an error occurs.

```

...
ws.onerror = function(error)
{
  if (nbMessReceived === 0)
    statusFld.innerHTML = "";
  statusFld.innerHTML += ((nbMessReceived === 0?"": "<br>") + "<small>" +
    (new Date()).format("d-M-Y H:i:s_ Z") +
    "</small>:<font color='red'>" + error.err +
"</font>");
  statusFld.scrollTop = statusFld.scrollHeight;
  nbMessReceived++;
};
...

```

Example 18–36 Handling a Connection Closed Event for a JavaScript WebSocket Client

This example uses standard JavaScript functions to display the current date and time followed by the message `Connection closed` when a connection is closed.

```

...
ws.onclose = function()
{
  if (nbMessReceived === 0)
    statusFld.innerHTML = "";
  statusFld.innerHTML += ((nbMessReceived === 0?"": "<br>") + "<small>" +
    (new Date()).format("d-M-Y H:i:s_ Z") +
    "</small>:<font color='blue'>" + ' Connection closed' +
    "</font>");
  promptFld.innerHTML = 'Connection closed';
};
...

```

18.18.1.4 Sending a Message from a JavaScript WebSocket Client

To send a message from a JavaScript WebSocket client:

1. Define a function for sending the message.
2. In the body of the function for sending the message, call the `send` function of the `WebSocket` object.
3. Call the function that you defined for sending the message.

The following examples shows how to send a message from a JavaScript WebSocket client:

- [Example 18–37](#)
- [Example 18–38](#)

Example 18–37 Defining a Function for Sending a Message

This example defines the function `send` for sending a message.

The creation of the `ws` `WebSocket` object in this example is shown in [Example 18–32](#).

```
...
var send = function(mess)
{
    ws.send(mess);
};
...
```

Example 18–38 Calling a Function for Sending a Message

This example calls the `send` function for sending the contents of the text field when the user clicks `Send`.

The definition of the `send` function is shown in [Example 18–37](#).

```
...
<input type="text" id="input" style="border-radius:2px; border:1px solid #ccc;
margin-top:10px; padding:5px; width:400px;"
placeholder="Type your message here"/>
<button
onclick="javascript:send(document.getElementById('input').value);">Send</button>
...
```

18.18.2 Packaging and Specifying the Location of the WebSocket Fallback Client Library

Package the `orasocket.min.js` file in the `scripts` directory of your web application.

In the client application, add the following `script` element to specify the location of `orasocket.min.js`.

```
<script type="text/javascript" src="scripts/orasocket.min.js"></script>
```

18.18.3 Enabling WebSocket Fallback

By default, `WebSocket` fallback is disabled.

To enable `WebSocket` fallback, set the `com.oracle.tyrus.fallback.enabled` context parameter to `true` in the application's deployment descriptor file `web.xml`.

```
<?xml version="1.1" encoding="UTF-8"?>
<web-app version="3.0" ...>
...
<context-param>
    <description>Enable fallback mechanism</description>
    <param-name>com.oracle.tyrus.fallback.enabled</param-name>
    <param-value>true</param-value>
</context-param>
</web-app>
```

18.19 Migrating an Application to the JSR 356 Java API for WebSocket from the Deprecated API

As of WebLogic Server 12.1.3, the packages `weblogic.websocket` and `weblogic.websocket.annotation` are deprecated and will be removed in a future release. After these packages have been removed, you will no longer be able to use these packages for connections over the WebSocket protocol.

To ensure compatibility of your WebSocket applications with future releases of WebLogic Server, use the JSR 356 Java API for WebSocket instead of the deprecated packages.

18.19.1 Comparison of the JSR 356 API and Proprietary WebLogic Server WebSocket API

Table 18–10 shows the proprietary WebLogic Server WebSocket API and the corresponding JSR 356 API to use to perform tasks for developing a WebSocket application. The table shows only the JSR 356 API to use for an annotated endpoint. For each task, the table also provides a cross-reference to instructions for performing the task by using the JSR 356 API.

Table 18–10 Comparison of the JSR 356 API and Proprietary WebLogic Server WebSocket API

Task	Proprietary WebLogic Server WebSocket API	JSR 356 API	Instructions
Create a server endpoint class	<ol style="list-style-type: none"> 1. <code>WebSocketListener</code> interface or <code>WebSocketAdapter</code> superclass 2. <code>WebSocket</code> annotation 	<code>ServerEndpoint</code> annotation	Creating an Annotated Endpoint
Handle a connection opened event	<code>onOpen</code> method of a <code>WebSocketListener</code> object	<code>OnOpen</code> annotation on the method that handles the event	Handling a Connection Opened Event
Handle a message received event	One of the following variants of the overloaded <code>onMessage</code> method of a <code>WebSocketListener</code> object: <ul style="list-style-type: none"> ■ For a message that consists of a text data frame: <code>onMessage(WebSocketConnection connection, String payload)</code> ■ For a message that consists of a binary data frame: <code>onMessage(WebSocketConnection connection, byte[] payload)</code> 	<code>OnMessage</code> annotation on the method that handles the event	Handling a Message Received Event
Handle an error event	<code>onError</code> method of a <code>WebSocketListener</code> object	<code>OnError</code> annotation on the method that handles the event	Handling an Error Event
Handle a connection closed event	<code>onClose</code> method of a <code>WebSocketListener</code> object	<code>OnClose</code> annotation on the method that handles the event	Handling a Connection Closed Event

Table 18–10 (Cont.) Comparison of the JSR 356 API and Proprietary WebLogic Server WebSocket API

Task	Proprietary WebLogic Server WebSocket API	JSR 356 API	Instructions
Send a message	One of the following methods of a <code>WebSocketConnection</code> object: <ul style="list-style-type: none"> ■ <code>send(String message)</code> ■ <code>send(byte[] message)</code> ■ <code>sendPing</code> ■ <code>sendPong</code> ■ <code>stream(boolean last, String fragment)</code> ■ <code>stream(boolean last, byte[] fragment, int off, int length)</code> 	<ol style="list-style-type: none"> 1. <code>Session</code> interface 2. One of the following methods of the <code>Session</code> object: <ul style="list-style-type: none"> <code>getBasicRemote()</code> <code>getAsyncRemote()</code> 3. One of the following methods of the <code>RemoteEndpoint.Basic</code> object or <code>RemoteEndpoint.Async</code> object: <ul style="list-style-type: none"> <code>sendText</code> <code>sendBinary</code> <code>sendPing</code> <code>sendPong</code> 	Sending a Message to a Single Peer of an Endpoint
Send a message to all peers connected to an endpoint	<ol style="list-style-type: none"> 1. <code>getWebSocketContext</code> method of a <code>WebSocketConnection</code> object 2. <code>getWebSocketConnections</code> method of the <code>WebSocketContext</code> object obtained by the previous call 	<code>getOpenSessions</code> method of the <code>Session</code> object	Sending a Message to All Peers of an Endpoint
Set the maximum message size for a WebSocket connection	<code>maxMessageSize</code> element of the <code>WebSocket</code> annotation	<code>maxMessageSize</code> element of the <code>onMessage</code> annotation	
Set the idle timeout value for a WebSocket connection	<code>timeout</code> element of the <code>WebSocket</code> annotation	One of the following APIs: <ul style="list-style-type: none"> ■ For an individual connection: <code>setMaxIdleTimeout</code> method of the <code>Session</code> object ■ For the entire container: <code>setDefaultMaxSessionIdleTimeout</code> method of a <code>WebSocketContainer</code> object 	
Set the maximum number of open connections on a WebSocket connection	<code>maxConnections</code> element of the <code>WebSocket</code> annotation	Not supported by JSR 356 Java API for WebSocket	

18.19.2 Converting a Proprietary WebSocket Server Endpoint to Use the JSR 356 API

To convert a proprietary WebSocket server endpoint to use the JSR 356 API:

1. Convert your `WebSocket` class to an annotated server endpoint class.

Converting a `WebSocket` class to an annotated endpoint class requires fewer changes than converting the `WebSocket` class to a programmatic endpoint class.

- a. Convert the `WebSocket` class to a POJO class by removing the `extends WebSocketAdapter` clause or `implements WebSocketListener` clause from the class declaration.
- b. Replace the `weblogic.websocket.annotation.WebSocket` annotation on the class declaration with the `javax.websocket.server.ServerEndpoint` annotation.

For more information, see [Creating an Annotated Endpoint](#).

Note: If the `pathPatterns` element of your existing endpoint contains the `/*` suffix, you must rewrite your code to achieve the same result as the `/*` suffix. For more information, see [Replacing the /* Suffix in a Path Pattern String](#).

2. Annotate the declaration of each method for handling a life cycle event with the annotation that designates the event that the method handles.

For more information, see [Handling Life Cycle Events in an Annotated WebSocket Endpoint](#).

3. Replace each reference to the `weblogic.websocket.WebSocketConnection` interface with a reference to the `javax.websocket.Session` interface.
4. Replace each method invocation on the `WebSocketConnection` object with an invocation of the corresponding method on the `Session` object.

For example, the `close` method of a `WebSocketConnection` object takes a `weblogic.websocket.ClosingMessage` object as a parameter. In the `close` method of a `Session` object the corresponding parameter is a `javax.websocket.CloseReason` object.

5. Change each method invocation on a `Session` object to send a message as follows:
 - a. Add an invocation of the `getBasicRemote` method or `getAsyncRemote` method to obtain a reference to the object that represents the peer of this endpoint.
 - b. Replace the method in the deprecated API for sending the message with the corresponding method in the JSR 356 API.

The method of the JSR 356 API is a method of the `javax.websocket.RemoteEndpoint.Basic` object or `javax.websocket.RemoteEndpoint.Async` object to which you obtained a reference in the previous step.

For more information, see [Sending a Message](#).

Deprecated API Method	RemoteEndpoint.Basic Method	RemoteEndpoint.Async Method
<code>send(String message)</code>	<code>sendText(String text)</code>	One of the following methods: <code>sendText(String text)</code> <code>sendText(String text, SendHandler handler)</code>
<code>send(byte[] message)</code>	<code>sendBinary(ByteBuffer data)</code>	One of the following methods: <code>sendBinary(ByteBuffer data)</code> <code>sendBinary(ByteBuffer data, SendHandler handler)</code>
<code>sendPing(byte[] message)</code>	<code>sendPing(ByteBuffer applicationData)</code>	<code>sendPing(ByteBuffer applicationData)</code>

Deprecated API Method	RemoteEndpoint.Basic Method	RemoteEndpoint.Async Method
<code>sendPong(byte[] message)</code>	<code>sendPong(ByteBuffer applicationData)</code>	<code>sendPong(ByteBuffer applicationData)</code>
<code>stream(boolean last, String fragment)</code>	<code>sendText(String partialMessage, boolean isLast)</code>	No corresponding method.
<code>stream(boolean last, byte[] fragment, int off, int length)</code>	<code>sendBinary(ByteBuffer partialByte, boolean isLast)</code>	No corresponding method.

6. Replace references in `import` clauses to classes in the deprecated API with references to the classes in the JSR 356 API that your endpoint uses.
7. Recompile and re-deploy the application that uses the server endpoint.

18.19.3 Replacing the /* Suffix in a Path Pattern String

The `pathPatterns` element of the `WebSocket` annotation in the deprecated API accepts the `/*` suffix in a path pattern string. The `/*` suffix matches the path pattern with any resource path that starts with the path pattern before the `/*` suffix. For example, the resource path `/ws/chat` is matched by path pattern `/ws/*`.

No equivalent to the `/*` suffix exists in the JSR 356 API. If your existing endpoint relies on the `/*` suffix, you must rewrite your code to achieve the same result as the `/*` suffix. How to rewrite your code depends on whether the `/*` suffix represents variable path parameters in an endpoint URI or additional data for an endpoint.

18.19.3.1 Replacing a /* Suffix that Represents Variable Path Parameters in an Endpoint URI

The `/*` suffix in a path pattern string might represent one or more variable path parameters in an endpoint URI. In this situation, use a URI template instead of the `/*` suffix.

The JSR 356 API supports only level 1 URI templates in which path parameters are clearly separated by slashes (/). Therefore, in the URI template, you must define one variable for expansion for each variable path parameter that replaces the `/*` suffix in your existing endpoint.

For example, if one variable path parameter replaces the `/*` suffix in your existing endpoint, define a URI template similar to the following example:

```
/ws/{param1}
```

The URI `/ws/test` matches the template in the preceding example. The `param1` variable is expanded to `test`.

Similarly, if two variable path parameters replace the `/*` suffix in your existing endpoint, define a URI template similar to the following example:

```
/ws/{param1}/{param2}
```

The URI `/ws/test/chat` matches the template in the preceding example. The `param1` variable is expanded to `test` and the `param2` variable is expanded to `chat`.

For more information, see [Specifying a Part of an Endpoint Deployment URI as an Application Parameter](#).

18.19.3.2 Replacing a /* Suffix that Represents Additional Data for an Endpoint

The /* suffix in a path pattern string might represent additional data for an endpoint that is transferred as part of the URI. In this situation, use query parameters instead of the /* suffix.

The JSR 356 specification does not forbid or restrict the use of query parameters in any way. Therefore, you can use a query parameter to transfer any data provided that the following conditions are met:

- URLs are shorter than their maximum allowed length.
- All data is properly encoded.

To obtain an endpoint's query parameters, invoke the method of the endpoint's `Session` object that obtains the parameters in the required format:

- To obtain the parameters as a single string that contains the entire query, invoke the `getQueryString` method. See [Example 18–39](#).
- To obtain the parameters as a map that contains a list of query parameters, invoke the `getRequestParameterMap` method. See [Example 18–40](#).

Example 18–39 *Obtaining Query Parameters as a Single String*

This example obtains the query parameters in the request URI `/echo?foo=bar,baz,mane,padme,hum` as the application output `# foo=bar,baz,mane,padme,hum`.

```
import javax.websocket.OnOpen;
import javax.websocket.Session;
import javax.websocket.server.ServerEndpoint;
...
@ServerEndpoint("/echo")
public class EchoEndpoint {

    @OnOpen
    public void onOpen(Session session) throws IOException {
        System.out.println("# " + session.getQueryString());
    }

    // ...
}
```

Example 18–40 *Obtaining Query Parameters as a Map*

This example obtains the query parameters in the request URI `/echo?foo=bar&foo=baz&foo=mane&foo=padme&foo=hum` as the `List<String>` `# [bar, baz, mane, padme, hum]`.

```
import javax.websocket.OnOpen;
import javax.websocket.Session;
import javax.websocket.server.HandshakeRequest;
import javax.websocket.server.ServerEndpoint;
import java.util.List;
import java.util.Map;
...
@ServerEndpoint("/echo")
public class EchoEndpoint {

    @OnOpen
    public void onOpen(Session session) throws IOException {
```

```

        System.out.println("# " + session.getRequestParameterMap().get("foo"));
    }

    // ...
}

```

18.19.4 Example of Converting a Proprietary WebSocket Server Endpoint to Use the JSR 356 API

[Example 18–41](#) shows how to convert a proprietary WebSocket server endpoint to use the JSR 356 API from the deprecated API.

Example 18–41 *Converting a WebSocket Server Endpoint to Use the JSR 356 API*

This example shows the changes that are required to convert a WebSocket server endpoint to the use JSR 356 API instead of the deprecated API.

In this example, lines of deprecated code are commented out with the // comment characters. Lines of code from the JSR 356 API are indicated by the comment //JSR 356.

```

package examples.webapp.html5.websocket;

//import weblogic.websocket.ClosingMessage;           Deprecated
//import weblogic.websocket.WebSocketAdapter;         Deprecated
//import weblogic.websocket.WebSocketConnection;      Deprecated
//import weblogic.websocket.annotation.WebSocket;     Deprecated

import javax.websocket.CloseReason;                  //JSR 356
import javax.websocket.OnMessage;                    //JSR 356
import javax.websocket.Session;                      //JSR 356
import javax.websocket.server.ServerEndpoint;        //JSR 356

import java.io.IOException;

//@WebSocket(   Deprecated
// timeout = -1,   Deprecated
// pathPatterns = {"ws"}   Deprecated
//)
@ServerEndpoint("/ws") //JSR 356
//public class MessageListener extends WebSocketAdapter {   Deprecated
public class MessageListener {
//@Override Not required. Replaced by @OnMessage in a POJO class
@OnMessage //JSR 356
//public void onMessage(WebSocketConnection connection, String payload) {
Deprecated
public void onMessage(Session connection, String payload) //JSR 356
throws IOException { //JSR 356
    // Sends message from the browser back to the client.
    String msgContent = "Message \" + payload + "\" has been received by
server.";
    try {
//    connection.send(msgContent);   Deprecated
        connection.getBasicRemote().sendText(msgContent); //JSR 356
    } catch (IOException e) {
//    connection.close(ClosingMessage.SC_GOING_AWAY);   Deprecated
        connection.close(new //JSR 356
            CloseReason(CloseReason.CloseCodes.GOING_AWAY, "Going away.");//JSR 356
        );
    }
}
}

```

```
    }  
}
```

18.20 Example of Using the Java API for WebSocket with WebLogic Server

[Example 18–42](#) uses the Java API for WebSocket with WebLogic Server. This example is a server endpoint that echoes text that a user has sent from a client. When the user sends a text message, the server appends the text (`from your server`) to the message and sends the message back to the user.

Example 18–42 Using the Java API for WebSocket with WebLogic Server

```
package com.example.websocket.sample.echo;  
  
import java.io.IOException;  
  
import javax.websocket.OnError;  
import javax.websocket.OnMessage;  
import javax.websocket.OnOpen;  
import javax.websocket.Session;  
import javax.websocket.server.ServerEndpoint;  
  
@ServerEndpoint("/echo")  
public class EchoEndpoint {  
  
    @OnOpen  
    public void onOpen(Session session) throws IOException {  
        session.getBasicRemote().sendText("onOpen is invoked.");  
    }  
  
    @OnMessage  
    public String echo(String message) {  
        return message + " (from server)";  
    }  
  
    @OnError  
    public void onError(Throwable t) {  
        t.printStackTrace();  
    }  
  
}
```

Enterprise Application Deployment Descriptor Elements

This appendix describes enterprise application deployment descriptors: `application.xml` (a Java EE standard deployment descriptor) and `weblogic-application.xml` (a WebLogic-specific application deployment descriptor).

With Java EE annotations, the standard `application.xml` deployment descriptor is optional. Annotations simplify the application development process by allowing developers to specify within the Java class itself how the application component behaves in the container, requests for dependency injection, and so on. Annotations are an alternative to deployment descriptors that were required by older versions of enterprise applications (Java EE 1.4 and earlier). See [Chapter 8, "Using Java EE Annotations and Dependency Injection."](#)

The `weblogic-application.xml` file is also optional if you are not using any WebLogic Server extensions.

This appendix includes the following sections:

- [Section A.1, "weblogic-application.xml Deployment Descriptor Elements"](#)
- [Section A.2, "weblogic-application.xml Schema"](#)
- [Section A.3, "application.xml Schema"](#)

A.1 weblogic-application.xml Deployment Descriptor Elements

The following sections describe the many of the individual elements that are defined in the [weblogic-application.xml Schema](#). The `weblogic-application.xml` file is the WebLogic Server-specific deployment descriptor extension for the `application.xml` Java EE deployment descriptor. This is where you configure features such as shared Java EE libraries referenced in the application and EJB caching.

The file is located in the `META-INF` subdirectory of the application archive. The following sections describe elements that can appear in the file.

A.1.1 weblogic-application

The `weblogic-application` element is the root element of the application deployment descriptor.

The following table describes the elements you can define within a `weblogic-application` element.

Table A-1 *weblogic-application* Elements

Element	Required?	Maximum Number In File	Description
<ejb>	Optional	1	<p>Contains information that is specific to the EJB modules that are part of a WebLogic application. Currently, one can use the <code>ejb</code> element to specify one or more application level caches that can be used by the application's entity beans.</p> <p>For more information on the elements you can define within the <code>ejb</code> element, see Section A.1.2, "ejb".</p>
<xml>	Optional	1	<p>Contains information about parsers and entity mappings for XML processing that is specific to this application.</p> <p>For more information on the elements you can define within the <code>xml</code> element, see Section A.1.4, "xml".</p>
<jdbc-connection-pool>	Optional	Unbounded	<p>Zero or more. Specifies an application-scoped JDBC connection pool.</p> <p>For more information on the elements you can define within the <code>jdbc-connection-pool</code> element, see Section A.1.5, "jdbc-connection-pool".</p>
<security>	Optional	1	<p>Specifies security information for the application.</p> <p>For more information on the elements you can define within the <code>security</code> element, see Section A.1.6, "security".</p>
<application-param>	Optional	Unbounded	<p>Zero or more. Used to specify un-typed parameters that affect the behavior of container instances related to the application. The parameters listed here are currently supported. Also, these parameters in <code>weblogic-application.xml</code> can determine the default encoding to be used for requests and for responses.</p> <ul style="list-style-type: none"> ■ <code>webapp.encoding.default</code>—Can be set to a string representing an encoding supported by the JDK. If set, this defines the default encoding used to process servlet requests and servlet responses. This setting is ignored if <code>webapp.encoding.usevmdefault</code> is set to <code>true</code>. This value is also overridden for request streams by the <code>input-charset</code> element of <code>weblogic.xml</code>. ■ <code>webapp.encoding.usevmdefault</code>—Can be set to <code>true</code> or <code>false</code>. If <code>true</code>, the system property <code>file.encoding</code> is used to define the default encoding. <p>The following parameter is used to affect the behavior of Web applications that are contained in this application.</p> <ul style="list-style-type: none"> ■ <code>webapp.getrealpath.accept_context_path</code>—This is a compatibility switch that may be set to <code>true</code> or <code>false</code>. If set to <code>true</code>, the context path of Web applications is allowed in calls to the servlet API <code>getRealPath</code>. <p>Example:</p> <pre><application-param> <param-name>webapp.encoding.default </param-name> <param-value>UTF8</param-value> </application-param></pre> <p>For more information on the elements you can define within the <code>application-param</code> element, see Section A.1.7, "application-param".</p>

Table A-1 (Cont.) weblogic-application Elements

Element	Required?	Maximum Number In File	Description
<code><classloader-structure></code>	Optional	Unbounded	<p>A classloader-structure element allows you to define the organization of classloaders for this application. The declaration represents a tree structure that represents the classloader hierarchy and associates specific modules with particular nodes. A module's classes are loaded by the classloader that its associated with this element.</p> <p>Example:</p> <pre><classloader-structure> <module-ref> <module-uri>ejb1.jar</module-uri> </module-ref> </classloader-structure> <classloader-structure> <module-ref> <module-uri>ejb2.jar</module-uri> </module-ref> </classloader-structure></pre> <p>For more information on the elements you can define within the <code>classloader-structure</code> element, see Section A.1.8, "classloader-structure".</p>
<code><listener></code>	Optional	Unbounded	<p>Zero or more. Used to register user-defined application lifecycle listeners. These are classes that extend the abstract base class <code>weblogic.application.ApplicationLifecycleListener</code>.</p> <p>For more information on the elements you can define within the <code>listener</code> element, see Section A.1.9, "listener".</p>
<code><singleton-service></code>	Optional	Unbounded	<p>Zero or more. Used to register user-defined singleton services. These are classes that implement the interface <code>weblogic.cluster.singleton.SingletonService</code>.</p> <p>For more information on the elements you can define within the <code>singleton-service</code> element, see Section A.1.10, "singleton-service".</p>
<code><startup></code>	Optional	Unbounded	<p>Zero or more. Used to register user-defined startup classes.</p> <p>For more information on the elements you can define within the <code>startup</code> element, see Section A.1.11, "startup".</p> <p>Note: Application-scoped startup and shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Instead, you should use lifecycle listener events in your applications. For details, see Chapter 13, "Programming Application Life Cycle Events"</p>
<code><shutdown></code>	Optional	Unbounded	<p>Zero or more. Used to register user defined shutdown classes.</p> <p>For more information on the elements you can define within the <code>shutdown</code> element, see Section A.1.12, "shutdown".</p> <p>Note: Application-scoped startup and shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Instead, you should use lifecycle listener events in your applications. For details, see Chapter 13, "Programming Application Life Cycle Events."</p>

Table A-1 (Cont.) weblogic-application Elements

Element	Required?	Maximum Number In File	Description
<module>	Optional	Unbounded	<p>Represents a single WebLogic application module, such as a JMS or JDBC module.</p> <p>This element has the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the module. ■ type—The type of module. Valid values are JMS, JDBC, Interception, or GAR. ■ path—The path of the XML file that fully describes the module, relative to the root of the enterprise application. <p>The following example shows how to specify a JMS module called <code>Workflows</code>, fully described by the XML file <code>jms/Workflows-jms.xml</code>:</p> <pre><module> <name>Workflows</name> <type>JMS</type> <path>jms/Workflows-jms.xml</path> </module></pre>
<library-ref>	Optional	Unbounded	<p>A reference to a shared Java EE library.</p> <p>For more information on the elements you can define within the <code>library</code> element, see Section A.1.15, "library-ref".</p>
<fair-share-request>	Optional	Unbounded	<p>Specifies a fair share request class, which is a type of Work Manager request class. In particular, a fair share request class specifies the average percentage of thread-use time required to process requests.</p> <p>The <fair-share-request> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the fair share request class. ■ fair-share—An integer representing the average percentage of thread-use time. <p>See "Using Work Managers to Optimize Scheduled Work".</p>
<response-time-request>	Optional	Unbounded	<p>Specifies a response time request class, which is a type of Work manager class. In particular, a response time request class specifies a response time goal in milliseconds.</p> <p>The <response-time-request> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the response time request class. ■ goal-ms—The integer response time goal. <p>See "Using Work Managers to Optimize Scheduled Work".</p>

Table A-1 (Cont.) weblogic-application Elements

Element	Required?	Maximum Number In File	Description
<context-request>	Optional	Unbounded	<p>Specifies a context request class, which is a type of Work manager class. In particular, a context request class assigns request classes to requests based on context information, such as the current user or the current user's group.</p> <p>The <context-request> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the context request class. ■ context-case—An element that describes the context. <p>The <context-case> element can itself take the following child elements:</p> <ul style="list-style-type: none"> ■ user-name or group-name—The user or group to which the context applies. ■ request-class-name—The name of the request class. <p>See "Using Work Managers to Optimize Scheduled Work".</p>
<max-threads-constraint>	Optional	Unbounded	<p>Specifies a max-threads-constraint Work Manager constraint. A Work Manager constraint defines minimum and maximum numbers of threads allocated to execute requests and the total number of requests that can be queued or executing before WebLogic Server begins rejecting requests.</p> <p>The max-threads constraint limits the number of concurrent threads executing requests from the constrained work set.</p> <p>The <max-threads-constraint> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the max-thread-constraint. ■ Either count or pool-name—The integer maximum number of concurrent threads, or the name of a connection pool which determines the maximum. <p>See "Using Work Managers to Optimize Scheduled Work".</p>
<min-threads-constraint>	Optional	Unbounded	<p>Specifies a min-threads-constraint Work Manager constraint. A Work Manager constraint defines minimum and maximum numbers of threads allocated to execute requests and the total number of requests that can be queued or executing before WebLogic Server begins rejecting requests.</p> <p>The min-threads constraint guarantees a number of threads the server will allocate to affected requests to avoid deadlocks.</p> <p>The <min-threads-constraint> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the min-thread-constraint. ■ count—The integer minimum number of threads. <p>See "Using Work Managers to Optimize Scheduled Work".</p>

Table A-1 (Cont.) weblogic-application Elements

Element	Required?	Maximum Number In File	Description
<capacity>	Optional	Unbounded	<p>Specifies a capacity Work Manager constraint. A Work Manager constraint defines minimum and maximum numbers of threads allocated to execute requests and the total number of requests that can be queued or executing before WebLogic Server begins rejecting requests.</p> <p>The capacity constraint causes the server to reject requests only when it has reached its capacity.</p> <p>The <capacity> element can take the following child elements:</p> <ul style="list-style-type: none"> ■ name—The name of the capacity constraint. ■ count—The integer thread capacity. <p>See "Using Work Managers to Optimize Scheduled Work".</p>
<work-manager>	Optional	Unbounded	<p>Specifies the Work Manager that is associated with the application.</p> <p>For more information on the elements you can define within the <code>work-manager</code> element, see Section A.1.13, "work-manager".</p> <p>See "Using Work Managers to Optimize Scheduled Work" for detailed information on Work Managers.</p>
<application-admin-mode-trigger>	Optional	Unbounded	<p>Specifies the number of stuck threads needed to bring the application into administration mode.</p> <p>You can specify the following child elements:</p> <ul style="list-style-type: none"> ■ max-stuck-thread-time—The maximum amount of time, in seconds, that a thread should remain stuck. ■ stuck-thread-count—Number of stuck threads that triggers the stuck thread work manager. <p>Once the stuck thread condition is cleared, the application automatically returns to running mode.</p>
<session-descriptor>	Optional	Unbounded	<p>Specifies a list of configuration parameters for servlet sessions.</p> <p>For more information on the elements you can define within the <session-descriptor> element, see Section A.1.14, "session-descriptor".</p>
<library-context-root-override>	Optional	Unbounded	<p>Zero or more. Used to override the context-root of a Web module specified in the deployment descriptor of a library referenced by this application.</p> <p>For more information on the elements you can define within the <library-context-root-override> element, see Section A.1.16, "library-context-root-override".</p>
<component-factory-class-name>	Optional	1	<p>Used to enable the Spring extension by setting this element to <code>org.springframework.jee.interfaces.SpringComponentFactory</code>. This element exists in EJB, Web, and application descriptors. A module-level descriptor overwrites an application-level descriptor. If set to null (default), the Spring extension is disabled.</p>

Table A-1 (Cont.) weblogic-application Elements

Element	Required?	Maximum Number In File	Description
<prefer-application-packages>	Optional	1	Used for filtering ClassLoader configuration. Specifies a list of packages for classes that must always be loaded from the application.
<prefer-application-resources>	Optional	1	Used for filtering ClassLoader configuration. Specifies a list of resources that must always be loaded from the application, even if the resources are found in the system classloader. Note that the resource loading behavior is different from the resource loading behavior when <prefer-application-packages> is used. In that case, application resources get a preference over system resources. The resources captured in this element are never looked up in the system classloader.
<fast-swap>	Optional	1	Specifies whether FastSwap deployment is used to minimize redeployment since Java classes are redefined in-place without reloading the ClassLoader. For more information, see "Using FastSwap Deployment to Minimize Redeployment" in <i>Deploying Applications to Oracle WebLogic Server</i> . For information on the elements you can define within the <fast-swap> element, see Section A.1.17, "fast-swap" .

A.1.2 ejb

The following table describes the elements you can define within an ejb element.

Table A-2 *ejb Elements*

Element	Required?	Maximum Number in File	Description
<entity-cache>	Optional	Unbounded	<p>Zero or more. The <code>entity-cache</code> element is used to define a named application level cache that is used to cache entity EJB instances at runtime. Individual entity beans refer to the application-level cache that they must use, referring to the cache name. There is no restriction on the number of different entity beans that may reference an individual cache.</p> <p>To use application-level caching, you must specify the cache using the <code><entity-cache-ref></code> element of the <code>weblogic-ejb-jar.xml</code> descriptor. Two default caches named <code>ExclusiveCache</code> and <code>MultiVersionCache</code> are used for this purpose. An application may explicitly define these default caches to specify non-default values for their settings. Note that the <code>caching-strategy</code> cannot be changed for the default caches. By default, a cache uses <code>max-beans-in-cache</code> with a value of 1000 to specify its maximum size.</p> <p>Example:</p> <pre><entity-cache> <entity-cache-name>ExclusiveCache</entity-cache-name> <max-cache-size> <megabytes>50</megabytes> </max-cache-size> </entity-cache></pre> <p>For more information on the elements you can define within the <code>entity-cache</code> element, see Section A.1.2.1, "entity-cache".</p>
<start-mbds-with-application>	Optional	1	<p>Allows you to configure the EJB container to start Message Driven Beans (MDBS) with the application. If set to true, the container starts MDBS as part of the application. If set to false, the container keeps MDBS in a queue and the server starts them as soon as it has started listening on the ports.</p>

A.1.2.1 entity-cache

The following table describes the elements you can define within a `entity-cache` element.

Table A-3 *entity-cache Elements*

Element	Required?	Maximum Number in File	Description
<entity-cache-name>	Required	1	Specifies a unique name for an entity bean cache. The name must be unique within an ear file and may not be the empty string. Example: <entity-cache-name>ExclusiveCache</entity-cache-name>
<max-beans-in-cache>	Optional If you specify this element, you cannot also specify <max-cache-size>.	1	Specifies the maximum number of entity beans that are allowed in the cache. If the limit is reached, beans may be passivated. This mechanism does not take into account the actual amount of memory that different entity beans require. This element can be set to a value of 1 or greater. Default Value: 1000
<max-cache-size>	Optional If you specify this element, you cannot also specify <max-beans-in-cache>.	1	Used to specify a limit on the size of an entity cache in terms of memory size—expressed either in terms of bytes or megabytes. A bean provider should provide an estimate of the average size of a bean in the weblogic-ejb-jar.xml descriptor if the bean uses a cache that specifies its maximum size using the max-cache-size element. By default, a bean is assumed to have an average size of 100 bytes. For more information on the elements you can define within the ejb element, see Section A.1.3, "max-cache-size" .
<max-queries-in-cache>	Optional	1	Specifies the maximum SQL queries that can be present in the entity cache at a given moment.
<caching-strategy>	Optional	1	Specifies the general strategy that the EJB container uses to manage entity bean instances in a particular application level cache. A cache buffers entity bean instances in memory and associates them with their primary key value. The caching-strategy element can only have one of the following values: <ul style="list-style-type: none"> ■ Exclusive—Caches a single bean instance in memory for each primary key value. This unique instance is typically locked using the EJB container's exclusive locking when it is in use, so that only one transaction can use the instance at a time. ■ MultiVersion—Caches multiple bean instances in memory for a given primary key value. Each instance can be used by a different transaction concurrently. Default Value: MultiVersion Example: <caching-strategy>Exclusive</caching-strategy>

A.1.3 max-cache-size

The following table describes the elements you can define within a max-cache-size element.

Table A-4 *max-cache-size Elements*

Element	Required?	Maximum Number in File	Description
<bytes>	You <i>must</i> specify either <bytes> or <megabytes>	1	The size of an entity cache in terms of memory size, expressed in bytes.
<megabytes>	You <i>must</i> specify either <bytes> or <megabytes>	1	The size of an entity cache in terms of memory size, expressed in megabytes.

A.1.4 xml

The following table describes the elements you can define within an `xml` element.

Table A-5 *xml Elements*

Element	Required?	Maximum Number in File	Description
<parser-factory>	Optional	1	The parent element used to specify a particular XML parser or transformer for an enterprise application. For more information on the elements you can define within the <code>parser-factory</code> element, see Section A.1.4.1, "parser-factory" .
<entity-mapping>	Optional	Unbounded	Zero or More. Specifies the entity mapping. This mapping determines the alternative entity URI for a given public or system ID. The default place to look for this entity URI is the <code>lib/xml/registry</code> directory. For more information on the elements you can define within the <code>entity-mapping</code> element, see Section A.1.4.2, "entity-mapping" .

A.1.4.1 parser-factory

The following table describes the elements you can define within a `parser-factory` element.

Table A-6 *parser-factory Elements*

Element	Required?	Maximum Number in File	Description
<saxparser-factory>	Optional	1	Allows you to set the SAXParser Factory for the XML parsing required in this application only. This element determines the factory to be used for SAX style parsing. If you do not specify the saxparser-factory element setting, the configured SAXParser Factory style in the Server XML Registry is used. Default Value: Server XML Registry setting
<document-builder-factory>	Optional	1	Allows you to set the Document Builder Factory for the XML parsing required in this application only. This element determines the factory to be used for DOM style parsing. If you do not specify the document-builder-factory element setting, the configured DOM style in the Server XML Registry is used. Default Value: Server XML Registry setting
<transformer-factory>	Optional	1	Allows you to set the Transformer Engine for the style sheet processing required in this application only. If you do not specify a value for this element, the value configured in the Server XML Registry is used. Default value: Server XML Registry setting.

A.1.4.2 entity-mapping

The following table describes the elements you can define within an entity-mapping element.

Table A-7 *entity-mapping Elements*

Element	Required?	Maximum Number in File	Description
<entity-mapping-name>	Required	1	Specifies the name for this entity mapping.
<public-id>	Optional	1	Specifies the public ID of the mapped entity.
<system-id>	Optional	1	Specifies the system ID of the mapped entity.
<entity-uri>	Optional	1	Specifies the entity URI for the mapped entity.
<when-to-cache>	Optional	1	Legal values are: <ul style="list-style-type: none"> ■ cache-on-reference ■ cache-at-initialization ■ cache-never The default value is cache-on-reference.
<cache-timeout-integer>	Optional	1	Specifies the integer value in seconds.

A.1.5 jdbc-connection-pool

Note: The `jdbc-connection-pool` element is deprecated. To define a data source in your enterprise application, you can package a JDBC module with the application. For more information, see "Configuring JDBC Application Modules for Deployment" in *Administering JDBC Data Sources for Oracle WebLogic Server*.

The following table describes the elements you can define within a `jdbc-connection-pool` element.

Table A-8 *jdbc-connection-pool Elements*

Element	Required?	Maximum Number in File	Description
<code><data-source-jndi-name></code>	Required	1	Specifies the JNDI name in the application-specific JNDI tree.
<code><connection-factory></code>	Required	1	Specifies the connection parameters that define overrides for default connection factory settings. <ul style="list-style-type: none"> ▪ <code>user-name</code>—Optional. The <code>user-name</code> element is used to override <code>UserName</code> in the <code>JDBCDataSourceFactoryMBean</code>. ▪ <code>url</code>—Optional. The <code>url</code> element is used to override URL in the <code>JDBCDataSourceFactoryMBean</code>. ▪ <code>driver-class-name</code>—Optional. The <code>driver-class-name</code> element is used to override <code>DriverName</code> in the <code>JDBCDataSourceFactoryMBean</code>. ▪ <code>connection-params</code>—Zero or more. ▪ <code>parameter+ (param-value, param-name)</code>—One or more For more information on the elements you can define within the <code>connection-factory</code> element, see Section A.1.5.1, "connection-factory" .
<code><pool-params></code>	Optional	1	Defines parameters that affect the behavior of the pool. For more information on the elements you can define within the <code>pool-params</code> element, see Section A.1.5.2, "pool-params" .
<code><driver-params></code>	Optional	1	Sets behavior on WebLogic Server drivers. For more information on the elements you can define within the <code>driver-params</code> element, see Section A.1.5.3, "driver-params" .
<code><acl-name></code>	Optional	1	DEPRECATED.

A.1.5.1 connection-factory

The following table describes the elements you can define within a `connection-factory` element.

Table A-9 *connection-factory Elements*

Element	Required?	Maximum Number in File	Description
<factory-name>	Optional	1	Specifies the name of a JDBCDataSourceFactoryMBean in the config.xml file.
<connection-properties>	Optional	1	<p>Specifies the connection properties for the connection factory. Elements that can be defined for the connection-properties element are:</p> <ul style="list-style-type: none"> ▪ user-name—Optional. Used to override UserName in the JDBCDataSourceFactoryMBean. ▪ password—Optional. Used to override Password in the JDBCDataSourceFactoryMBean. ▪ url—Optional. Used to override URL in the JDBCDataSourceFactoryMBean. ▪ driver-class-name—Optional. Used to override DriverName in the JDBCDataSourceFactoryMBean ▪ connection-params—Zero or more. Used to set parameters which will be passed to the driver when making a connection. Example: <pre><connection-params> <parameter> <description>Desc of param </description> <param-name>foo</param-name> <param-value>xyz</param-value> </parameter> </connection-params></pre>

A.1.5.2 pool-params

The following table describes the elements you can define within a pool-params element.

Table A-10 *pool-params Elements*

Element	Required?	Maximum Number in File	Description
<size-params>	Optional	1	<p>Defines parameters that affect the number of connections in the pool.</p> <ul style="list-style-type: none"> ■ <code>initial-capacity</code>—Optional. The <code>initial-capacity</code> element defines the number of physical database connections to create when the pool is initialized. The default value is 1. ■ <code>max-capacity</code>—Optional. The <code>max-capacity</code> element defines the maximum number of physical database connections that this pool can contain. Note that the JDBC Driver may impose further limits on this value. The default value is 1. ■ <code>capacity-increment</code>—Optional. The <code>capacity-increment</code> element defines the increment by which the pool capacity is expanded. When there are no more available physical connections to service requests, the pool creates this number of additional physical database connections and adds them to the pool. The pool ensures that it does not exceed the maximum number of physical connections as set by <code>max-capacity</code>. The default value is 1. ■ <code>shrinking-enabled</code>—Optional. The <code>shrinking-enabled</code> element indicates whether or not the pool can shrink back to its <code>initial-capacity</code> when connections are detected to not be in use. ■ <code>shrink-period-minutes</code>—Optional. The <code>shrink-period-minutes</code> element defines the number of minutes to wait before shrinking a connection pool that has incrementally increased to meet demand. The <code>shrinking-enabled</code> element must be set to <code>true</code> for shrinking to take place. ■ <code>shrink-frequency-seconds</code>—Optional. ■ <code>highest-num-waiters</code>—Optional. ■ <code>highest-num-unavailable</code>—Optional.

Table A-10 (Cont.) pool-params Elements

Element	Required?	Maximum Number in File	Description
<xa-params>	Optional	1	<p>Defines the parameters for the XA DataSources.</p> <ul style="list-style-type: none"> ■ <code>debug-level</code>—Optional. Integer. The <code>debug-level</code> element defines the debugging level for XA operations. The default value is 0. ■ <code>keep-conn-until-tx-complete-enabled</code>—Optional. Boolean. If you set the <code>keep-conn-until-tx-complete-enabled</code> element to true, the XA connection pool associates the same XA connection with the distributed transaction until the transaction completes. ■ <code>end-only-once-enabled</code>—Optional. Boolean. If you set the <code>end-only-once-enabled</code> element to true, the <code>XAResource.end()</code> method is only called once for each pending <code>XAResource.start()</code> method. ■ <code>recover-only-once-enabled</code>—Optional. Boolean. If you set the <code>recover-only-once-enabled</code> element to true, <code>recover</code> is only called one time on a resource. ■ <code>tx-context-on-close-needed</code>—Optional. Set the <code>tx-context-on-close-needed</code> element to true if the XA driver requires a distributed transaction context when closing various JDBC objects (for example, result sets, statements, connections, and so on). If set to true, the SQL exceptions that are thrown while closing the JDBC objects in no transaction context are swallowed. ■ <code>new-conn-for-commit-enabled</code>—Optional. Boolean. If you set the <code>new-conn-for-commit-enabled</code> element to true, a dedicated XA connection is used for commit/rollback processing of a particular distributed transaction.
<xa-params> Continued...	Optional	1	<ul style="list-style-type: none"> ■ <code>prepared-statement-cache-size</code>—Deprecated. Optional. Use the <code>prepared-statement-cache-size</code> element to set the size of the prepared statement cache. The size of the cache is a number of prepared statements created from a particular connection and stored in the cache for further use. Setting the size of the prepared statement cache to 0 turns it off. <p>Note: <code>Prepared-statement-cache-size</code> is deprecated. Use <code>cache-size</code> in <code>driver-params/prepared-statement</code>. See Section A.1.5.3, "driver-params" for more information.</p> <ul style="list-style-type: none"> ■ <code>keep-logical-conn-open-on-release</code>—Optional. Boolean. Set the <code>keep-logical-conn-open-on-release</code> element to true, to keep the logical JDBC connection open when the physical XA connection is returned to the XA connection pool. The default value is false. ■ <code>local-transaction-supported</code>—Optional. Boolean. Set the <code>local-transaction-supported</code> to true if the XA driver supports SQL with no global transaction; otherwise, set it to false. The default value is false. ■ <code>resource-health-monitoring-enabled</code>—Optional. Set the <code>resource-health-monitoring-enabled</code> element to true to enable JTA resource health monitoring for this connection pool.

Table A-10 (Cont.) pool-params Elements

Element	Required?	Maximum Number in File	Description
<xa-params> Continued...	Optional	1	<ul style="list-style-type: none"> ■ xa-set-transaction-timeout—Optional. Used in: xa-params Example: <pre><xa-set-transaction-timeout> true </xa-set-transaction-timeout></pre> ■ xa-transaction-timeout—Optional. When the <code>xa-set-transaction-timeout</code> value is set to <code>true</code>, the transaction manager invokes <code>setTransactionTimeout</code> on the resource before calling <code>XAResource.start</code>. The Transaction Manager passes the global transaction timeout value. If this attribute is set to a value greater than 0, then this value is used in place of the global transaction timeout. Default value: 0 Used in: xa-params Example: <pre><xa-transaction-timeout> 30 </xa-transaction-timeout></pre> ■ rollback-localtx-upon-connclose—Optional. When the <code>rollback-localtx-upon-connclose</code> element is <code>true</code>, the connection pool calls <code>rollback()</code> on the connection before putting it back in the pool. Default value: <code>false</code> Used in: xa-params Example: <pre><rollback-localtx-upon-connclose> true </rollback-localtx-upon-connclose></pre>
<login-delay-second s>	Optional	1	Sets the number of seconds to delay before creating each physical database connection. Some database servers cannot handle multiple requests for connections in rapid succession. This property allows you to build in a small delay to let the database server catch up. This delay occurs both during initial pool creation and during the lifetime of the pool whenever a physical database connection is created.
<leak-profiling-ena bled>	Optional	1	Enables JDBC connection leak profiling. A connection leak occurs when a connection from the pool is not closed explicitly by calling the <code>close()</code> method on that connection. When connection leak profiling is active, the pool stores the stack trace at the time the connection object is allocated from the pool and given to the client. When a connection leak is detected (when the connection object is garbage collected), this stack trace is reported. This element uses extra resources and will likely slowdown connection pool operations, so it is not recommended for production use.

Table A-10 (Cont.) pool-params Elements

Element	Required?	Maximum Number in File	Description
<connection-check-params>	Optional	1	<ul style="list-style-type: none"> ■ Defines whether, when, and how connections in a pool is checked to make sure they are still alive. ■ <code>table-name</code>—Optional. The <code>table-name</code> element defines a table in the schema that can be queried. ■ <code>check-on-reserve-enabled</code>—Optional. If the <code>check-on-reserve-enabled</code> element is set to <code>true</code>, then the connection will be tested each time before it is handed out to a user. ■ <code>check-on-release-enabled</code>—Optional. If the <code>check-on-release-enabled</code> element is set to <code>true</code>, then the connection will be tested each time a user returns a connection to the pool. ■ <code>refresh-minutes</code>—Optional. If the <code>refresh-minutes</code> element is defined, a trigger is fired periodically (based on the number of minutes specified). This trigger checks each connection in the pool to make sure it is still valid. ■ <code>check-on-create-enabled</code>—Optional. If set to <code>true</code>, then the connection will be tested when it is created. ■ <code>connection-reserve-timeout-seconds</code>—Optional. Number of seconds after which the call to reserve a connection from the pool will timeout. ■ <code>connection-creation-retry-frequency-seconds</code>—Optional. The frequency of retry attempts by the pool to establish connections to the database. ■ <code>inactive-connection-timeout-seconds</code>—Optional. The number of seconds of inactivity after which reserved connections will forcibly be released back into the pool.
<connection-check-params> Continued...	Optional	1	<ul style="list-style-type: none"> ■ <code>test-frequency-seconds</code>—Optional. The number of seconds between database connection tests. After every <code>test-frequency-seconds</code> interval, unused database connections are tested using <code>table-name</code>. Connections that do not pass the test will be closed and reopened to re-establish a valid physical database connection. If <code>table-name</code> is not set, the test will not be performed. ■ <code>init-sql</code>—Optional. Specifies a SQL query that automatically runs when a connection is created.
<jdbcxa-debug-level>	Optional	1	This is an internal setting.
<remove-infected-connections-enabled>	Optional	1	Controls whether a connection is removed from the pool when the application asks for the underlying vendor connection object. Enabling this attribute has an impact on performance; it essentially disables the pooling of connections (as connections are removed from the pool and replaced with new connections).

A.1.5.3 driver-params

The following table describes the elements you can define within a `driver-params` element.

Table A-11 *driver-params Elements*

Element	Required?	Maximum Number in File	Description
<statement>	Optional	1	<p>Defines the driver-params statement. Contains the following optional element: profiling-enabled.</p> <p>Example:</p> <pre><statement> <profiling-enabled>true </profiling-enabled> </statement></pre>
<prepared-statement	Optional	1	<p>Enables the running of JDBC prepared statement cache profiling. When enabled, prepared statement cache profiles are stored in external storage for further analysis. This is a resource-consuming feature, so it is recommended that you turn it off on a production server. The default value is false.</p> <ul style="list-style-type: none"> ■ profiling-enabled—Optional. ■ cache-profiling-threshold—Optional. The cache-profiling-threshold element defines a number of statement requests after which the state of the prepared statement cache is logged. This element minimizes the output volume. This is a resource-consuming feature, so it is recommended that you turn it off on a production server. ■ cache-size—Optional. The cache-size element returns the size of the prepared statement cache. The size of the cache is a number of prepared statements created from a particular connection and stored in the cache for further use. ■ parameter-logging-enabled—Optional. During SQL roundtrip profiling it is possible to store values of prepared statement parameters. The parameter-logging-enabled element enables the storing of statement parameters. This is a resource-consuming feature, so it is recommended that you turn it off on a production server. ■ max-parameter-length—Optional. During SQL roundtrip profiling it is possible to store values of prepared statement parameters. The max-parameter-length element defines maximum length of the string passed as a parameter for JDBC SQL roundtrip profiling. This is a resource-consuming feature, so you should limit the length of data for a parameter to reduce the output volume. ■ cache-type—Optional.

Table A-11 (Cont.) driver-params Elements

Element	Required?	Maximum Number in File	Description
<row-prefetch-enabled>	Optional	1	Specifies whether to enable row prefetching between a client and WebLogic Server for each ResultSet. When an external client accesses a database using JDBC through WebLogic Server, row prefetching improves performance by fetching multiple rows from the server to the client in one server access. WebLogic Server ignores this setting and does not use row prefetching when the client and WebLogic Server are in the same JVM
<row-prefetch-size>	Optional	1	Specifies the number of result set rows to prefetch for a client. The optimal value depends on the particulars of the query. In general, increasing this number increases performance, until a particular value is reached. At that point further increases do not result in any significant increase in performance. Note: Typically you will not see any increase in performance after 100 rows. The default value should be adequate for most situations. Valid values for this element are between 2 and 65536. The default value is 48.
<stream-chunk-size>	Optional	1	Specifies the data chunk size for streaming data types, which are pulled from WebLogic Server to the client as needed.

A.1.6 security

The following table describes the elements you can define within a security element.

Table A-12 security Elements

Element	Required?	Maximum Number in File	Description
<realm-name>	Optional	1	Names a security realm to be used by the application. If none is specified, the system default realm is used
<security-role-assignment>	Optional	Unbounded	Declares a mapping between an application-wide security role and one or more WebLogic Server principals. Example: <pre><security-role-assignment> <role-name> PayrollAdmin </role-name> <principal-name> Tanya </principal-name> <principal-name> Fred </principal-name> <principal-name> system </principal-name> </security-role-assignment></pre>

A.1.7 application-param

The following table describes the elements you can define within a `application-param` element.

Table A-13 *application-param Elements*

Element	Required?	Maximum Number in File	Description
<code><description></code>	Optional	1	Provides a description of the application parameter.
<code><param-name></code>	Required	1	Defines the name of the application parameter.
<code><param-value></code>	Required	1	Defines the value of the application parameter.

A.1.8 classloader-structure

The following table describes the elements you can define within a `classloader-structure` element.

Table A-14 *classloader-structure Elements*

Element	Required?	Maximum Number in File	Description
<code><module-ref></code>	Optional	Unbounded	The following list describes the elements you can define within a <code>module-ref</code> element: <ul style="list-style-type: none"> ▪ <code>module-uri</code>—Zero or more. Defined within the <code>module-ref</code> element.
<code><classloader-structure></code>	Optional	Unbounded	Allows for arbitrary nesting of classloader structures for an application. However, for this version of WebLogic Server, the depth is restricted to three levels.

A.1.9 listener

The following table describes the elements you can define within a `listener` element.

Table A–15 *listener Elements*

Element	Required?	Maximum Number in File	Description
<listener-class>	Required	1	Name of the user's implementation of <code>ApplicationLifecycleListener</code> .
<listener-uri>	Optional	1	A JAR file within the EAR that contains the implementation. If you do not specify the <code>listener-uri</code> , it is assumed that the class is visible to the application.
<run-as-principal-name>	Optional	1	Specific a user identity to startup and shutdown application lifecycle events. The identity specified here should be a valid user name in the system. If <code>run-as-principal-name</code> is not specified, the deployment initiator user identity will be used as the <code>run-as</code> identity for the execution of the application lifecycle listener. Note: If the <code>run-as-principal-name</code> identity defined for the application lifecycle listener is an administrator, the application deployer must have administrator privileges; otherwise, deployment will fail.

A.1.10 singleton-service

The following table describes the elements you can define within a `singleton-service` element.

Table A–16 *singleton-service Elements*

Element	Required?	Maximum Number in File	Description
<class-name>	Required	1	Defines the name of the class to be run when the application is being deployed.
<singleton-uri>	Optional	1	Defines a JAR file within the EAR that contains the <code>singleton-service</code> . If <code>singleton-uri</code> is not defined, then its assumed that the class is visible to the application.

A.1.11 startup

The following table describes the elements you can define within a `startup` element.

Note:: Application-scoped startup and shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Instead, you should use lifecycle listener events in your applications. For details, see [Chapter 13, "Programming Application Life Cycle Events."](#)

Table A-17 *startup Elements*

Element	Required?	Maximum Number in File	Description
<startup-class>	Required	1	Defines the name of the class to be run when the application is being deployed.
<startup-uri>	Optional	1	Defines a JAR file within the EAR that contains the startup-class. If startup-uri is not defined, then its assumed that the class is visible to the application.

A.1.12 shutdown

The following table describes the elements you can define within a shutdown element.

Note : Application-scoped startup and shutdown classes have been deprecated as of release 9.0 of WebLogic Server. Instead, you should use lifecycle listener events in your applications. For details, see [Chapter 13, "Programming Application Life Cycle Events."](#)

Table A-18 *shutdown Elements*

Element	Required	Optional	Maximum Number in File	Description
<shutdown-class>	Required		1	Defines the name of the class to be run when the application is undeployed.
<shutdown-uri>		Optional	1	Defines a JAR file within the EAR that contains the shutdown-class. If you do not define the shutdown-uri element, it is assumed that the class is visible to the application.

A.1.13 work-manager

The following table describes the elements you can define within a work-manager element.

See "Using Work Managers to Optimize Scheduled Work" for examples and information on Work Managers.

Table A-19 *work-manager Elements*

Element	Required?	Maximum Number in File	Description
<name>	Required	1	The name of the Work Manager.
<response-time-request-class>	Optional	1	See the description of the <response-time-request> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <fair-share-request-class>, <context-request-class>, or <request-class-name>.</p>
<fair-share-request-class>	Optional	1	See the description of the <fair-share-request> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <response-time-request-class>, <context-request-class>, or <request-class-name>.</p>
<context-request-class>	Optional	1	See the description of the <context-request> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <fair-share-request-class>, <response-time-request-class>, or <request-class-name>.</p>
<request-class-name>	Optional	1	The name of the request class. <p>If you specify this element, you cannot also specify <fair-share-request-class>, <context-request-class>, or <response-time-request-class>.</p>
<min-threads-constraint>	Optional	1	See the description of the <min-threads-constraint> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <min-threads-constraint-name>.</p>
<min-threads-constraint-name>	Optional	1	The name of the min-threads constraint. <p>If you specify this element, you cannot also specify <min-threads-constraint>.</p>
<max-threads-constraint>	Optional	1	See the description of the <max-threads-constraint> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <max-threads-constraint-name>.</p>
<max-threads-constraint-name>	Optional	1	The name of the max-threads constraint. <p>If you specify this element, you cannot also specify <max-threads-constraint>.</p>
<capacity>	Optional	1	See the description of the <capacity> element in Section A.1.1, "weblogic-application" for information on this child element of <work-manager>. <p>If you specify this element, you cannot also specify <capacity-name>.</p>

Table A–19 (Cont.) work-manager Elements

Element	Required?	Maximum Number in File	Description
<capacity-name>	Optional	1	The name of the thread capacity constraint. If you specify this element, you cannot also specify <capacity>.
<work-manager-shutdown-trigger>	Optional	1	Used to specify a Stuck Thread Work Manager component that can shut down the Work Manager in response to stuck threads. You can specify the following child elements: <ul style="list-style-type: none"> max-stuck-thread-time—The maximum amount of time, in seconds, that a thread should remain stuck. stuck-thread-count—Number of stuck threads that triggers the stuck thread work manager. If you specify this element, you cannot also specify <ignore-stuck-threads>.
<ignore-stuck-threads>	Optional	1	Specifies whether the Work Manager should ignore stuck threads and never shut down even if threads become stuck. If you specify this element, you cannot also specify <work-manager-shutdown-trigger>.

A.1.14 session-descriptor

The following table describes the elements you can define within a session-descriptor element.

Table A–20 session-descriptor Elements

Element	Required?	Maximum Number in File	Description
<timeout-secs>	Optional	1	Specifies the number of seconds after which the session times out. Default value is 3600 seconds.
<invalidation-interval-secs>	Optional	1	Specifies the number of seconds of the invalidation trigger interval. Default value is 60 seconds.
<debug-enabled>	Optional	1	Specifies whether debugging is enabled for HTTP sessions. Default value is false.
<id-length>	Optional	1	Specifies the length of the session ID. Default value is 52.
<tracking-enabled>	Optional	1	Specifies whether session tracking is enabled between HTTP requests. Default value is true.
<cache-size>	Optional	1	Specifies the cache size for JDBC and file persistent sessions. Default value is 1028.

Table A-20 (Cont.) session-descriptor Elements

Element	Required?	Maximum Number in File	Description
<max-in-memory-sessions>	Optional	1	Specifies the maximum sessions limit for memory/replicated sessions. Default value is -1, or unlimited.
<cookies-enabled>	Optional	1	Specifies the Web application container should set cookies in the response. Default value is true.
<cookie-name>	Optional	1	Specifies the name of the cookie that tracks sessions. Default name is JSESSIONID.
<cookie-path>	Optional	1	Specifies the session tracking cookie path. Default value is /.
<cookie-domain>	Optional	1	Specifies the session tracking cookie domain. Default value is null.
<cookie-comment>	Optional	1	Specifies the session tracking cookie comment. Default value is null.
<cookie-secure>	Optional	1	Specifies whether the session tracking cookie is marked secure. Default value is false.
<cookie-max-age-secs>	Optional	1	Specifies that maximum age of the session tracking cookie. Default value is -1, or unlimited.
<persistent-store-type>	Optional	1	Specifies the type of storage for session persistence. You can specify the following values: <ul style="list-style-type: none"> ■ memory—Default value. ■ replicated—Requires clustering. ■ replicated_if_clustered—Defaults to memory in non-clustered case. ■ file ■ jdbc ■ cookie
<persistent-store-cookie-name>	Optional	1	Specifies the name of the cookie that holds the attribute name and values when using cookie-based session persistence. Default value is WLCOOKIE.
<persistent-store-dir>	Optional	1	Specifies the name of the directory when using file-based session persistence. The directory is relative to the temporary directory defined for the Web application. Default value is session_db.
<persistent-store-pool>	Optional	1	Specifies the name of the JDBC connection pool when using jdbc-based session persistence.
<persistent-store-table>	Optional	1	Specifies the name of the database table when using jdbc-based session persistence. Default value is wl_servlet_sessions.

Table A–20 (Cont.) session-descriptor Elements

Element	Required?	Maximum Number in File	Description
<jdbc-column-name-max-in-active-interval>	Optional	1	Alternative name for the <code>wl_max_inactive_interval</code> column name when using jdbc-based session persistence. Required for certain databases that do not support long column names
<jdbc-connection-timeout-secs>	Optional	1	DEPRECATED
<url-rewriting-enabled>	Optional	1	Specifies whether URL rewriting is enabled. Default value is <code>true</code> .
<http-proxy-caching-of-cookies>	Optional	1	Specifies whether WebLogic Server adds the following HTTP header to the response: <code>Cache-control: no-cache=set-cookie</code> This header specifies that proxy caches should not cache the cookies. Default value is <code>true</code> , which means that the header is NOT added. Set this element to <code>false</code> if you want the header added to the response.
<encode-session-id-in-query-params>	Optional	1	Specifies whether WebLogic Server should encode the session ID in the path parameters. Default value is <code>false</code> .
<monitoring-attribute-name>	Optional	1	Used to tag runtime information for different sessions. For example, set this element to <code>username</code> if you have a <code>username</code> attribute that is guaranteed to be unique.
<sharing-enabled>	Optional	1	Specifies whether HTTP sessions are shared across multiple Web applications. Default value is <code>false</code> .

A.1.15 library-ref

The following table describes the elements you can define within a `library-ref` element.

See [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages,"](#) for additional information and examples.

Table A–21 library Elements

Element	Required?	Maximum Number in File	Description
<library-name>	Required	1	Specifies the name of the referenced shared Java EE library.
<specification-version>	Optional	1	Specifies the minimum specification-version required.

Table A-21 (Cont.) library Elements

Element	Required?	Maximum Number in File	Description
<implementation-version>	Optional	1	Specifies the minimum implementation-version required.
<exact-match>	Optional	1	Specifies whether there must be an exact match between the specification and implementation version that is specified and that of the referenced library. Default value is false.
<context-root>	Optional	1	Specifies the context-root of the referenced Web application's shared Java EE library.

A.1.16 library-context-root-override

The following table describes the elements you can define within a `library-context-root-override` element to override `context-root` elements within a referenced EAR library. See [Section A.1.15, "library-ref"](#).

See [Chapter 12, "Creating Shared Java EE Libraries and Optional Packages,"](#) for additional information and examples.

Table A-22 library-context-root-override Elements

Element	Required?	Maximum Number in File	Description
<context-root>	Optional	1	Overrides the <code>context-root</code> elements declared in libraries. In the absence of this element, the library's <code>context-root</code> is used. Only a referencing application (for example, a user application) can override the <code>context-root</code> elements declared in its libraries.
<override-value>	Optional	1	Specifies the value of the <code>library-context-root-override</code> element when overriding the <code>context-root</code> elements declared in libraries. In the absence of these elements, the library's <code>context-root</code> is used.

A.1.17 fast-swap

The following table describes the elements you can define within a `fast-swap` element.

For more information about FastSwap Deployment, see "Using FastSwap Deployment to Minimize Redeployment" in *Deploying Applications to Oracle WebLogic Server*.

Table A-23 *fast-swap Elements*

Element	Required?	Maximum Number in File	Description
<enabled>	Optional	1	Set to true to enable FastSwap deployment in your application.
<refresh-interval>	Optional	1	FastSwap checks for changes in application classes when an incoming HTTP request is received. Subsequent HTTP requests arriving within the <code>refresh-interval</code> seconds will not trigger a check for changes. The first HTTP request arriving after the <code>refresh-interval</code> seconds have passed, will cause FastSwap to perform a class-change check again.
<redefinition-task-limit>	Optional	1	FastSwap class redefinitions are performed asynchronously by redefinition tasks. They can be controlled and inspected using JMX interfaces. Specifies the number of redefinition tasks that will be retained by the FastSwap system. If the number of tasks exceeds this limit, older tasks are automatically removed.

A.2 weblogic-application.xml Schema

See

<http://xmlns.oracle.com/weblogic/weblogic-application/1.6/weblogic-application.xsd> for the XML Schema of the `weblogic-application.xml` deployment descriptor file.

A.3 application.xml Schema

For more information about `application.xml` deployment descriptor elements, see the Java EE 7 schema available at

http://www.oracle.com/webfolder/technetwork/jsc/xml/ns/javaee/application_7.xsd.

wldeploy Ant Task Reference

This appendix describes tools for deploying applications and standalone modules to WebLogic Server.

This appendix includes the following sections:

- [Section B.1, "Overview of the wldeploy Ant Task"](#)
- [Section B.2, "Basic Steps for Using wldeploy"](#)
- [Section B.3, "Sample build.xml Files for wldeploy"](#)
- [Section B.4, "wldeploy Ant Task Attribute Reference"](#)

B.1 Overview of the wldeploy Ant Task

The `wldeploy` Ant task enables you to perform `weblogic.Deployer` functions using attributes specified in an Ant XML file. You can use `wldeploy` along with other WebLogic Server Ant tasks to create a single Ant build script that:

- Builds your application from source, using `wlcompile`, `appc`, and the Web services Ant tasks.
- Creates, starts, and configures a new WebLogic Server domain, using the `wlserver` and `wlconfig` Ant tasks.
- Deploys a compiled application to the newly-created domain, using the `wldeploy` Ant task.

See [Chapter 2, "Using Ant Tasks to Configure and Use a WebLogic Server Domain,"](#) for more information about `wlserver` and `wlconfig`. See [Chapter 5, "Building Applications in a Split Development Directory,"](#) for information about `wlcompile`.

B.2 Basic Steps for Using wldeploy

To use the `wldeploy` Ant task:

1. Set your environment.

On Windows NT, execute the `setWLSEnv.cmd` command, located in the directory `WL_HOME\server\bin`, where `WL_HOME` is the top-level directory of your WebLogic Server installation.

On UNIX, execute the `setWLSEnv.sh` command, located in the directory `WL_HOME/server/bin`, where `WL_HOME` is the top-level directory of your WebLogic Server installation.

Note: On UNIX operating systems, the `setWLSEnv.sh` command does not set the environment variables in all command shells. Oracle recommends that you execute this command using the Korn shell or bash shell.

2. In the staging directory, create the Ant build file (`build.xml` by default). If you want to use an Ant installation that is different from the one installed with WebLogic Server, start by defining the `wldploy` Ant task definition:

```
<taskdef name="wldploy"
classloader="weblogic.ant.taskdefs.management.WLDeploy"/>
```

3. If necessary, add task definitions and calls to the `wlserver` and `wlconfig` tasks in the build script to create and start a new WebLogic Server domain. See [Chapter 2, "Using Ant Tasks to Configure and Use a WebLogic Server Domain,"](#) for information about `wlserver` and `wlconfig`.
4. Add a call to `wldploy` to deploy your application to one or more WebLogic Server instances or clusters. See [Section B.3, "Sample build.xml Files for wldploy"](#) and [Section B.4, "wldploy Ant Task Attribute Reference"](#).
5. Execute the Ant task or tasks specified in the `build.xml` file by typing `ant` in the staging directory, optionally passing the command a target argument:

```
prompt> ant
```

B.3 Sample build.xml Files for wldploy

The following example shows a `wldploy` target that deploys an application to a single WebLogic Server instance:

```
<target name="deploy">
  <wldploy
    action="deploy" verbose="true" debug="true"
    name="DeployExample" source="output/redeployEAR"
    user="weblogic" password="weblogic"
    adminurl="t3://localhost:7001" targets="myserver" />
</target>
```

The following example shows a corresponding task to undeploy the application; the example shows that when you undeploy or redeploy an application, you do not specify the source archive file or exploded directory, but rather, just its deployed name.:

```
<target name="undeploy">
  <wldploy
    action="undeploy" verbose="true" debug="true"
    name="DeployExample"
    user="weblogic" password="weblogic"
    adminurl="t3://localhost:7001" targets="myserver"
    failonerror="false" />
</target>
```

The following example shows how to perform a partial redeploy of the application; in this case, just a single WAR file in the application is redeployed:

```
<target name="redeploy_partial">
  <wldploy
    action="redeploy" verbose="true"
```

```

    name="DeployExample"
    user="weblogic" password="weblogic"
    adminurl="t3://localhost:7001" targets="myserver"
    deltaFiles="examples/general/redeploy/SimpleImpl.war" />
</target>

```

The following example uses the nested `<files>` child element of `wldploy` to specify a particular file in the application that should be undeployed:

```

<target name="undeploy_partial">
  <wldploy
    action="undeploy" verbose="true" debug="true"
    name="DeployExample"
    user="weblogic" password="weblogic"
    adminurl="t3://localhost:7001" targets="myserver"
    failonerror="false">
    <files
      dir="${current-dir}/output/redeployEAR/examples/general/redeploy"
      includes="SimpleImpl.jsp" />
  </wldploy>
</target>

```

The following example shows how to deploy a Java EE library called `myLibrary` whose source files are located in the `output/myLibrary` directory:

```

<target name="deploy">
  <wldploy action="deploy" name="myLibrary"
    source="output/myLibrary" library="true"
    user="weblogic" password="weblogic"
    verbose="true" adminurl="t3://localhost:7001"
    targets="myserver" />
</target>

```

B.4 wldploy Ant Task Attribute Reference

The following sections describe the attributes and child element `<files>` of the `wldploy` Ant task.

B.4.1 Main Attributes

The following table describes the main attributes of the `wldploy` Ant task.

These attributes mirror some of the arguments of the `weblogic.Deployer` command. Oracle provides an Ant task version of the `weblogic.Deployer` command so that developers can easily deploy and test their applications as part of the iterative development process. Typically, however, administrators use the `weblogic.Deployer` command, and not the `wldploy` Ant task, to deploy applications in a production environment. For that reason, see the "weblogic.Deployer Command-Line Reference" in *Deploying Applications to Oracle WebLogic Server* for the full and complete definition of the attributes of the `wldploy` Ant task. The table below is provided just as a quick summary.

Table B-1 Attributes of the wldploy Ant Task

Attribute	Description	Data Type
action	The deployment action to perform. Valid values are <code>deploy</code> , <code>cancel</code> , <code>undeploy</code> , <code>redploy</code> , <code>distribute</code> , <code>start</code> , and <code>stop</code> .	String
adminmode	Specifies that the deployment action puts the application into Administration mode. Administration mode restricts access to an application to a configured Administration channel. Valid values for this attribute are <code>true</code> and <code>false</code> . Default value is <code>false</code> , which means that by default the application is deployed in production mode so that all clients can access it immediately.	Boolean
adminurl	The URL of the Administration Server. The format of the value of this attribute is <code>protocol://host:port</code> , where <code>protocol</code> is either <code>http</code> or <code>t3</code> , <code>host</code> is the host on which the Administration Server is running, and <code>port</code> is the port which the Administration Server is listening. Note: In order to use the HTTP protocol, you must enable the <code>http</code> tunnelling option in the WebLogic Server Administration Console.	String
allversions	Specifies that the action (<code>redploy</code> , <code>stop</code> , and so on) applies to all versions of the application. Valid values for this attribute are <code>true</code> and <code>false</code> . The default value is <code>false</code> .	Boolean
altappdd	Specifies an alternate descriptor. May be used to specify an alternate <code>application.xml</code> for an <code>.ear</code> deployment or an alternate <code>web.xml</code> or <code>ejb.xml</code> for standalone module deployments.	String
altwlsappdd	Specifies the name of an alternate WebLogic Server deployment descriptor (<code>weblogic-application.xml</code>) to use for deployment. If you do not specify this attribute, and you are deploying an enterprise application, the default deployment descriptor is called <code>weblogic-application.xml</code> and is located in the META-INF subdirectory of the main application directory or archive (specified by the <code>source</code> attribute.)	String
appversion	The version identifier of the deployed application.	String
debug	Enable wldploy debugging messages.	Boolean
deleteFiles	Specifies whether to remove static files from a server's staging directory. This attribute is valid only for unarchived deployments, and only for applications deployed using <code>stage</code> mode. You must specify target servers when using this attribute. Specifying the <code>deleteFiles</code> attributes indicates that WebLogic Server should remove only those files that it copied to the staging area during deployment. This attribute can be used only in combination with <code>action="redploy"</code> . Because the <code>deleteFiles</code> attribute deletes all specified files, Oracle recommends that you use caution when using the <code>deleteFiles</code> attribute and that you do not use it in production environments. Valid values for this attribute are <code>true</code> and <code>false</code> . Default value is <code>false</code> .	Boolean
deltaFiles	Specifies a comma- or space-separated list of files, relative to the root directory of the application, which are to be redeployed. Use this attribute only in conjunction with <code>action="redploy"</code> to perform a partial redeploy of an application.	String
enableSecurityValidation	Specifies whether or not to enable validation of security data. Valid values for this attribute are <code>true</code> and <code>false</code> . Default value is <code>false</code> .	Boolean

Table B-1 (Cont.) Attributes of the wldploy Ant Task

Attribute	Description	Data Type
externalStage	<p>Specifies whether the deployment uses <code>external_stage</code> deployment mode.</p> <p>In this mode, the Ant task does not copy the deployment files to target servers; instead, you must ensure that deployment files have been copied to the correct subdirectory in the target servers' staging directories.</p> <p>You can specify only one of the following attributes: <code>stage</code>, <code>nostage</code>, or <code>external_stage</code>. If none is specified, the default deployment mode to Managed Servers is <code>stage</code>; the default mode to the Administration Server and in single-server cases is <code>nostage</code>.</p> <p>See "Controlling Deployment File Copying with Staging Modes".</p>	Boolean
failonerror	<p>This is a global attribute used by WebLogic Server Ant tasks. It specifies whether the task should fail if it encounters an error during the build.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>true</code>.</p>	Boolean
graceful	<p>Stops the application after existing HTTP clients have completed their work.</p> <p>You can use this attribute <i>only</i> when stopping or undeploying an application, or in other words, you must also specify either the <code>action="stop"</code> or <code>action="undeploy"</code> attributes.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p>	Boolean
id	<p>Identification used for obtaining status or cancelling the deployment.</p> <p>You assign a unique ID to an application when you deploy it, and then subsequently use the ID when redeploying, undeploying, stopping, and so on.</p> <p>If you do not specify this attribute, the Ant task assigns a unique ID to the application.</p>	String
ignoresessions	<p>This option immediately places the application into Administration mode without waiting for current HTTP sessions to complete.</p> <p>You can use this attribute <i>only</i> when stopping or undeploying an application, or in other words, you must also specify either the <code>action="stop"</code> or <code>action="undeploy"</code> attributes.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p>	Boolean
libImplVer	<p>Specifies the implementation version of a Java EE library or optional package.</p> <p>This attribute can be used only if the library or package does not include a implementation version in its manifest file. You can specify this attribute only in combination with the <code>library</code> attribute.</p> <p>See Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."</p>	String
library	<p>Identifies the deployment as a shared Java EE library or optional package. You must specify the <code>library</code> attribute when deploying or distributing any Java EE library or optional package.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p> <p>See Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."</p>	Boolean
libSpecVer	<p>Provides the specification version of a Java EE library or optional package.</p> <p>This attribute can be used only if the library or package does not include a specification version in its manifest file. You can specify this attribute only in combination with the <code>library</code> attribute.</p> <p>See Chapter 12, "Creating Shared Java EE Libraries and Optional Packages."</p>	String
name	<p>The deployment name for the deployed application.</p> <p>If you do not specify this attribute, WebLogic Server assigns a deployment name to the application, based on its archive file or exploded directory.</p>	String

Table B-1 (Cont.) Attributes of the wldploy Ant Task

Attribute	Description	Data Type
nostage	<p>Specifies whether the deployment uses nostage deployment mode.</p> <p>In this mode, the Ant task does not copy the deployment files to target servers, but leaves them in a fixed location, specified by the <code>source</code> attribute. Target servers access the same copy of the deployment files.</p> <p>You can specify only one of the following attributes: <code>stage</code>, <code>nostage</code>, or <code>external_stage</code>. If none is specified, the default deployment mode to Managed Servers is <code>stage</code>; the default mode to the Administration Server and in single-server cases is <code>nostage</code>.</p> <p>See "Controlling Deployment File Copying with Staging Modes".</p>	Boolean
noversion	<p>Indicates that the <code>wldploy</code> Ant task should ignore all version related code paths on the Administration Server. This behavior is useful when deployment source files are located on Managed Servers (not the Administration Server) and you want to use the <code>external_stage</code> staging mode.</p> <p>If you use this option, you cannot use versioned applications.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p>	Boolean
nowait	<p>Specifies whether <code>wldploy</code> returns immediately after making a deployment call (by deploying as a background task).</p>	Boolean
partition	<p>Specifies the name of the partition associated with the resource group on which you want to perform deployment actions for an application or library.</p> <p>You can specify the <code>partition</code> attribute for the following deployment actions: <code>deploy</code>, <code>undeploy</code>, <code>redploy</code>, <code>distribute</code>, <code>start</code>, and <code>stop</code>.</p> <p>The <code>partition</code> attribute is optional for partition administrators.</p> <p>For more information about deploying applications to partition resource groups, see "Deploying Applications" in <i>Using WebLogic Server MT</i>.</p>	String
password	<p>The administrative password.</p> <p>To avoid having the plain text password appear in the build file or in process utilities such as <code>ps</code>, first store a valid user name and encrypted password in a configuration file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command. Then omit both the <code>username</code> and <code>password</code> attributes in your Ant build file. When the attributes are omitted, <code>wldploy</code> attempts to login using values obtained from the default configuration file.</p> <p>If you want to obtain a user name and password from a non-default configuration file and key file, use the <code>userconfigfile</code> and <code>userkeyfile</code> attributes with <code>wldploy</code>.</p> <p>See the command reference for <code>storeUserConfig</code> in the <i>WLST Command Reference for WebLogic Server</i> for more information on storing and encrypting passwords.</p>	String
plan	<p>Specifies a deployment plan to use when deploying the application or module.</p> <p>By default, <code>wldploy</code> does not use an available deployment plan, even if you are deploying from an application root directory that contains a plan.</p>	String
planversion	<p>The version identifier of the deployment plan.</p>	String
remote	<p>Specifies whether the server is located on a different machine. This affects how filenames are transmitted.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>, which means that the Ant task assumes that all source paths are valid paths on the local machine.</p>	Boolean

Table B-1 (Cont.) Attributes of the wldploy Ant Task

Attribute	Description	Data Type
removePlanOverride	<p>Removes an overridden deployment plan during a <code>redeploy</code> or <code>update</code> deployment action.</p> <p>For applications or libraries deployed to a resource group, you can override the default application configuration defined in the resource group template that the resource group references. To remove an application override, specify the <code>removePlanOverride</code> attribute.</p> <p>You can specify the <code>removePlanOverride</code> attribute for the <code>redeploy</code> deployment actions.</p> <p>For more information about overriding application configuration, see "Overriding Application Configuration" in <i>Using WebLogic Server MT</i>.</p>	String
resourceGroup	<p>Specifies the name of the resource group at the partition or domain level on which you want to perform deployment actions for an application or library.</p> <p>For <code>deploy</code>, and <code>distribute</code> actions, you must specify the name of the resource group to which you want to deploy or distribute applications or libraries by setting the <code>resourceGroup</code> attribute. For partitions, if only one resource group exists in the specified partition, then the <code>resourceGroup</code> attribute is optional.</p> <p>For other supported deployment actions, you do not specify the <code>resourceGroup</code> attribute, as WebLogic Server derives the resource group from the unique application name.</p> <p>For more information about deploying applications to resource groups at the domain or partition level, see "Deploying Applications to Partition Resource Groups" in <i>Deploying Applications to Oracle WebLogic Server</i>.</p>	String
resourceGroupTemplate	<p>Specifies the name of the resource group template to which you want to perform a deployment action for an application or library.</p> <p>You can specify the <code>resourceGroupTemplate</code> attribute with the following deployment actions: <code>deploy</code>, <code>undeploy</code>, <code>redeploy</code>, and <code>distribute</code>.</p> <p>For more information about deploying applications to resource group templates, see "Application Deployment with Resource Group Templates" in <i>Deploying Applications to Oracle WebLogic Server</i>.</p>	String
retiretimeout	<p>Specifies the number of seconds before WebLogic Server undeploys the currently-running version of this application or module so that clients can start using the new version.</p> <p>It is assumed, when you specify this attribute, that you are starting, deploying, or redeploying a new version of an already-running application.</p> <p>See "Updating Applications in a Production Environment".</p>	int
securityModel	<p>Specifies the security model to use for this deployment. Possible security models are:</p> <ul style="list-style-type: none"> ■ Deployment descriptors only ■ Customize roles ■ Customize roles and policies ■ Security realm configuration (advanced model) <p>Valid actual values for this attribute are <code>DDOnly</code>, <code>CustomRoles</code>, <code>CustomRolesAndPolicy</code>, or <code>Advanced</code>.</p> <p>See "Options for Securing Web application and EJB Resources" for more information on these security models.</p>	String
source	The archive file or exploded directory to deploy.	File

Table B-1 (Cont.) Attributes of the wldploy Ant Task

Attribute	Description	Data Type
stage	<p>Specifies whether the deployment uses stage deployment mode.</p> <p>In this mode, the Ant task copies deployment files to target servers' staging directories.</p> <p>You can specify only one of the following attributes: <code>stage</code>, <code>nostage</code>, or <code>external_stage</code>. If none is specified, the default deployment mode to Managed Servers is <code>stage</code>; the default mode to the Administration Server and in single-server cases is <code>nostage</code>.</p> <p>See "Controlling Deployment File Copying with Staging Modes".</p>	Boolean
submoduletarget	<p>Specifies JMS server targets for resources defined within a JMS application module.</p> <p>The value of this attribute is a comma-separated list of JMS server names.</p> <p>See "Using Sub-Module Targeting with JMS Application Modules".</p>	String
targets	<p>The list of target servers to which the application is deployed.</p> <p>The value of this attribute is a comma-separated list of the target servers, clusters, or virtual hosts.</p> <p>If you do not specify a target list when deploying an application, the target defaults to the Administration Server instance.</p>	String
timeout	The maximum number of seconds to wait for a deployment to succeed.	int
upload	<p>Specifies whether the source file(s) are copied to the Administration Server's upload directory prior to deployment.</p> <p>Use this attribute when you are on a remote machine and you cannot copy the deployment files to the Administration Server by other means.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p>	Boolean
usenonexclusive	<p>Specifies that the deployment action (<code>deploy</code>, <code>redeploy</code>, <code>stop</code>, and so on) uses the existing lock on the domain that has already been acquired by the same user performing the action.</p> <p>This attribute is particularly useful when the user is using multiple deployment tools (Ant task, command line, WebLogic Server Administration Console, and so on) simultaneously and one of the tools has already acquired a lock on the domain.</p> <p>Valid values for this attribute are <code>true</code> and <code>false</code>. Default value is <code>false</code>.</p>	Boolean
user	The administrative user name.	String
userconfigfile	<p>Specifies the location of a user configuration file to use for obtaining the administrative user name and password. Use this option, instead of the <code>user</code> and <code>password</code> attributes, in your build file when you do not want to have the plain text password shown in-line or in process-level utilities such as <code>ps</code>.</p> <p>Before specifying the <code>userconfigfile</code> attribute, you must first generate the file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command as described in the <i>WLST Command Reference for WebLogic Server</i>.</p>	String
userkeyfile	<p>Specifies the location of a user key file to use for encrypting and decrypting the user name and password information stored in a user configuration file (the <code>userconfigfile</code> attribute).</p> <p>Before specifying the <code>userkeyfile</code> attribute, you must first generate the key file using the WebLogic Scripting Tool (WLST) <code>storeUserConfig</code> command as described in the <i>WLST Command Reference for WebLogic Server</i>.</p>	String
verbose	Specifies whether <code>wldploy</code> displays verbose output messages.	Boolean

B.4.2 Nested <files> Child Element

The wldploy Ant task also includes the <files> child element that can be nested to specify a list of files on which to perform a deployment action (for example, a list of JSPs to undeploy.)

Note : Use of <files> to redeploy a list of files in an application has been deprecated as of release 9.0 of WebLogic Server. Instead, use the deltaFiles attribute of wldploy.

The <files> element works the same as the standard <fileset> Ant task (except for the difference in actual task name). Therefore, see the Apache Ant Web site at <http://ant.apache.org/manual/Types/fileset.html> for detailed reference information about the attributes you can specify for the <files> element.
