Oracle® Fusion Middleware

Administering Oracle WebLogic Server with RESTful Management Services

12*c* (12.2.1.1.0)

E74649-02

August 2016

This document describes how to use Oracle WebLogic Server RESTful management interfaces for administration, monitoring, deploying, and configuration tasks which are exposed for developing RESTful clients.

Oracle Fusion Middleware Administering Oracle WebLogic Server with RESTful Management Services, 12c (12.2.1.1.0)

Preface

This preface describes the document accessibility features and conventions used in this guide— *Administering Oracle WebLogic Server with RESTful Management Services*.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

Introduction and Roadmap

This chapter describes the contents and organization of this guide—*Administering Oracle WebLogic Server with RESTful Management Services*.

Topics

- Document Scope and Audience
- · Guide to this Document
- Information Roadmap
- New and Changed Features In This Release

1.1 Document Scope and Audience

This document describes how to use Oracle WebLogic Server RESTful management interfaces for administration, monitoring, deploying, and configuration tasks which are exposed for developing RESTful clients. The user communities for this documentation are administrators who might use cURL commands to invoke these resources in administration scripts, and software developers who will use this information when writing code, perhaps in Java, perhaps in other languages, that monitors and manages WLS domains.

1.2 Guide to this Document

- This chapter, Introduction and Roadmap, describes the organization of this guide.
- About the WLS RESTful Management Interface provides an introduction to the WLS RESTful management interface, useful background and mapping information, and the HTTP status codes returned by WLS REST resources.
- Using the WLS RESTful Management Interface describes how to use the RESTful management services supported by WebLogic Server.
- Domain Level REST API Examples contains example scripts for users in domain level roles that show how to use the WLS REST APIs to perform common domain and partition management and monitoring tasks
- Partition Specific REST API Examples contains example scripts for users in partition level roles that show how to use the WLS REST APIs to perform common partition management and monitoring tasks.

1.3 Information Roadmap

WebLogic Server REST resources are based on WLS bean trees and organized according to their corresponding root resources. For more information, see Mapping the WLS Beans to REST.

The REST resources for managing WLS within specified partitions reside in separate manuals (MT reference guides). Each MT manual refers to resources accessible to partition user roles. Each non-MT manual refers to resources accessible to domain user roles. For more information about user roles in WebLogic Server Multitenant, see "Administrative Roles for Configuration and Management" in *Using WebLogic Server Multitenant*.

In the MT reference guides, REST resources:

- Are running in a partition.
- Must be accessed over a partitioned URL by a user defined in that partition's security realm.
- Only can be used to manage that partition.
- Cannot be used to manage all WLS MBeans. Many of the WLS MBeans are not available to partition users.

In the non-MT reference guides, REST resources:

- Run at the domain level (versus in a partition).
- Must be accessed over a non-partitioned URL by a user defined in the domain's default security realm.
- Can be used to manage all partitions.
- Can be used to manage all WLS MBeans.

See Table 1-1 for a complete listing of the WLS REST reference documents and descriptions of their use.

Book Title	Use These REST Resources To
RESTful Edit Reference for Oracle WebLogic Server	Edit the WLS configuration.
RESTful Domain Configuration Reference for Oracle WebLogic Server	View the last activated WLS configuration.
RESTful Domain Runtime Reference for Oracle WebLogic Server	Monitor the entire WLS domain.
RESTful Server Configuration Reference for Oracle WebLogic Server	View the WLS configuration that the Administration Server or Managed Server is currently running against.

Table 1-1 (Cont.) WLS RESTful Management Interface Reference Documentation

Book Title	Use These REST Resources To
RESTful Server Runtime Reference for Oracle WebLogic Server	Monitor the Administration Server or a Managed Server.
	You can monitor a Managed Server either by using the Administration Server's domainRuntime/serverRuntimes/ <managedservername>/ resources or the Managed Server's serverRuntime/ resources.</managedservername>
RESTful Edit Reference for Oracle WebLogic Server MT	Edit the WLS configuration in the specified domain partition.
RESTful Domain Configuration Reference for Oracle WebLogic Server MT	View the last activated WLS configuration in the specified domain partition.
RESTful Domain Runtime Reference for Oracle WebLogic Server MT	Monitor the specified WLS domain partition.
RESTful Server Configuration Reference for Oracle WebLogic Server MT	View the WLS configuration that the Administration Server is currently running against in the specified domain partition.
RESTful Server Runtime Reference for Oracle WebLogic Server MT	Monitor the Administration Server in the specified domain partition
RESTful Lifecycle Reference for Oracle WebLogic Server	Use WLS life cycle management REST resources.
RESTful Management Interface Reference for Oracle WebLogic Server	Legacy WLS RESTful management resources.

1.4 New and Changed Features In This Release

For a comprehensive listing of all the new WebLogic Server features introduced in this release, see What's New in Oracle WebLogic Server 12.2.1.1.0.

New a	and	Changed	Features	In	This	Release
-------	-----	---------	----------	----	------	---------

About the WLS RESTful Management Interface

WebLogic RESTful management services provide a comprehensive public interface for configuring, monitoring, deploying and administering WebLogic Server in all supported environments. This chapter describes the RESTful management services supported by WebLogic Server.

Topics

- Overview of the WLS RESTful Management Interface
- Mapping the WLS Beans to REST
- Standard REST Responses

2.1 Overview of the WLS RESTful Management Interface

In each release of WebLogic Server, the availability of REST resources for WebLogic Server administration has been enhanced and extended. This release provides comprehensive support for WebLogic Server administration through the dynamic generation of REST resources based on WLS MBeans and descriptor interfaces. There are resources to support the configuration and monitoring of partitioned and non-partitioned environments, life cycle management (LCM) resources, and legacy resources from 12.1.3.

For a guide to the WLS REST reference documentation, see the Information Roadmap.

Note:

In WebLogic Server 12.2.1, the dynamic REST resources supported one version,12.2.1.0, and the latest version referred to it. In 12.2.1.1, the dynamic REST resources support two versions:

- 12.2.1.0 (also referred to as 12.2.1.0.0): this version is now deprecated
- 12.2.1.1.0: this is the latest version

To summarize the changes in this release:

- The 12.2.1.0 REST resources have been deprecated and you should use the 12.2.1.1.0 REST resources instead
- The latest version has changed from 12.2.1.0 to 12.2.1.1.0
- All new MBean features have been added to the 12.2.1.1.0 and the 12.2.1.0
 REST resources, also

 Any MBean features that were deprecated in 12.2.1.1.0, will still be available using the 12.2.1.0 REST URLs, but not the 12.2.1.1.0 REST URLs

2.1.1 Generated REST API for WLS Bean Trees

WLS beans are used extensively by WLS components to manage configuration settings and to monitor and manage running servers.

The WLS beans are derived from Java interfaces. At runtime, WLS constructs internal trees of Java beans that can be used to configure and monitor the system. In prior releases, the bean trees were only exposed via JMX, WLST, and configuration files (for example, config.xml).

In this release, WLS dynamically generates REST resources, incrementally and ondemand at runtime, by using the bean trees and bean infos. These REST resources provide an alternative for managing WLS.

2.1.2 WLS Bean Tree Overview

The following sections provide background information about WLS beans which provide the foundation for the REST interfaces.

There are two main bean types:

- Configuration—used to configure WLS.
- Runtime—used to monitor WLS and for some operations, control WLS (for example, starting and stopping servers, shrinking data source connection pools).

WLS provides the following bean trees:

- Edit access—only available on the Administration Server, used to modify the configuration (for example, config.xml and system resource files).
- Runtime access—available on every server, used to view that server's configuration and to access its monitoring data.
- Domain access—only available on the Administration Server, contains copies of the runtime beans of all of the running servers, provides a single point of access for monitoring, is also used to view the most current configuration that has been persisted.

For more information about WLS MBeans, see "Understanding WebLogic Server MBeans" in *Developing Custom Management Utilities Using JMX for Oracle WebLogic Server*.

WebLogic Scripting Tool (WLST) presents the bean trees as follows:

- edit—matches the underlying edit access bean tree.
- domainConfig—the configuration MBean half of the domain access bean tree (such as, the last persisted configuration).
- domainRuntime—the runtime MBean half of the domain access bean tree (such as, for monitoring all servers).
- serverConfig—the configuration MBean half of the runtime access bean tree (such as, the configuration the server is using).

serverRuntime—the runtime MBean half of the runtime access bean tree (such as, for monitoring a specific server).

The REST resources parallel the MBean trees presentation in WLST: edit, domainConfig, domainRuntime, serverConfig, and serverRuntime.

Within the WLS bean trees, there are several types of parent/child (containment) relationships:

- Writable collections—for example, a domain bean has a collection of server beans.
- Mandatory singletons—for example, a server bean always has an SSL bean which is automatically created and cannot be deleted.
- Optional singletons—for example, an overload protection bean can optionally have a server failure trigger bean.

Beans can include properties (generally scalars, strings, and arrays), references to other beans, and operations (for example, to start a server).

With regard to contained collections:

- Each child has a unique identity within the collection (for example, each network channel has a name that's unique within its server).
- Most collections are homogeneous (for example, a domain's applications) though a few are heterogeneous (for example, a security realm's authentication providers).

2.2 Mapping the WLS Beans to REST

The following sections describe how WLS beans are mapped to the REST interfaces. Some commonalities are:

- All resource URLs contain version numbers, and support a version named latest. For more information, see "The {version} Specifier in Resource URLs" in the RESTful Management Interface Reference for Oracle WebLogic Server (Legacy).
- All request bodies and response bodies use JSON (media type is application/ json).
- Response bodies have a standard set of properties—items (to return information about collections), links (to return links to related resources), and messages (to return success, warning, and failure messages).
- All resources return standard HTTP response codes—201 for successful creation, 200 for other successes, 404 for not found, 400 for user input errors, 500 for internal server errors. For more information, see Standard REST Responses.

2.2.1 General REST Patterns

Almost all of the WLS beans (a homogeneous collection of children, a mandatory singleton child, and an optional homogenous singleton child) use the following REST patterns:

WLS Beans/REST Resource	REST Method	Description
Collections: collection resource	GET	Returns the collection.
resource	POST	Creates a new item in the collection.
Collections: create form resource	GET	Returns a pre-populated entity.
Collections: child resource	GET	Returns an item in the collection.
	POST	Updates an item in the collection.
	DELETE	Removes an item from the collection.
Singletons: singleton	GET	Returns the singleton.
resource	POST	Updates the singleton if it exists; creates it if it doesn't.
	DELETE	Removes the singleton.
Operations: action resource	POST	Invokes the operation.

2.2.2 Standard Request Headers

The following table describes the standard headers that clients should use to send WebLogic Server REST requests.

Request Header	Description
Accept:application/json	Indicates that the client wants the response to contain JSON. This header is appropriate when invoking the GET, POST, and DELETE methods. Any resources that return other data types are specified in the reference manual and examples.
Content- Type:application/json	Indicates that the client is sending in a request containing JSON. This header is appropriate for the POST method. Some methods support other content types (for example, when uploading deployments); the reference manual and examples specify when they are supported.
X-Requested-By:MyClient	Used to protect against Cross-Site Request Forgery (CSRF) attacks via REST. This header is mandatory for the POST and DELETE methods and ignored for the OPTIONS and GET methods.

2.2.3 About the Root Resources

The Administration Server and each running Managed Server hosts a REST web application that runs on each server's administrative port. The context root for each is management. The root REST resources mimic the bean trees in WLST.

Table 2-1 describes the root resources on the Administration Server and lists the corresponding bean tree.

Administration Server Root Resources Table 2-1

URL	Description	Corresponding Bean Tree
management/weblogic/ <version>/edit</version>	Edits the WLS configuration.	Administration Server's edit tree domain bean
management/weblogic/ <version>/ serverConfig</version>	Views the WLS configuration that the Administration Server is currently running against.	Administration Server's server runtime tree domain bean
management/weblogic/ <version>/ serverRuntime</version>	Monitors the Administration Server.	Administration Server's server runtime tree server runtime tree server
management/weblogic/ <version>/ domainConfig</version>	Views the last activated WLS configuration.	Administration Server's domain runtime tree domain bean
management/weblogic/ <version>/ domainRuntime</version>	Monitors the entire WLS domain.	Administration Server's domain runtime tree domain runtime bean
management/weblogic/ <version>/ domainRuntime/ serverRuntimes</version>	Monitors all the running servers in the WLS domain via the Administration Server.	Each running server's server runtime tree server runtime bean
<pre>management/weblogic/ <version>/ domainRuntime/ serverRuntimes/ <servername></servername></version></pre>	Monitors a specific running server in the WLS domain via the Administration Server.	The specified server's server runtime tree server runtime bean
management/lifecycle	Life cycle management (LCM) REST resources.	n/a
management/wls	12.1.3 (legacy) WLS REST resources.	n/a

Table 2-2 describes the root resources on Managed Servers.

Table 2-2 Managed Server Root Resources

URL	Description	Corresponding Bean Tree
<pre>management/weblogic/ <version>/ serverConfig</version></pre>	Views the WLS configuration that a Managed Server is currently running against.	Managed Server's server runtime tree domain bean
<pre>management/weblogic/ <version>/ serverRuntime</version></pre>	Monitors that Managed Server.	Managed Server's server runtime tree server runtime bean

The URLs on Managed Servers are exactly like the ones on the Administration Server, except that the host and port are different.

For example, to view the Administration Server's server runtime:

curl ... -X GET http://adminHost:7001/management/weblogic/ latest/serverRuntime

To view a Managed Server's server runtime:

curl ... -X GET http://managed1Host:7002/management/weblogic/ latest/serverRuntime

2.2.4 Naming Conventions

WLS bean property names are mapped to names in the REST URLs and JSON object properties. WLS property names usually start with an upper case letter (for example, Domain, JDBCDataSource, ServerRuntime) whereas the REST naming conventions use camel case, lower then upper case letters (for example, domain, JDBCDataSource, serverRuntime).

2.2.5 Mapping the REST URLs

Each WLS bean is mapped to a separate REST resource. Contained collections and operations are also mapped to separate resources. All WLS beans are either root resources (for example, the domain), contained collection children (for example, servers) or contained singleton children (for example, a server's SSL configuration).

The URLs for the root resources are listed in Table 2-1 and Table 2-2.

Each contained collection bean property maps to a URL for the entire collection as well as a URL for each child. For example:

URL	Description	Example
<pre><parent>/ <collectionpropertyname></collectionpropertyname></parent></pre>	Manages the entire collection.	/edit/servers
<pre><parent>/ <collectionpropertyname>/ <childname></childname></collectionpropertyname></parent></pre>	Manages a child in the collection.	/edit/servers/ Server-0

Similarly, each contained singleton bean property maps to its own URL. For example, a server's SSL bean maps to .../edit/servers/<serverName>/SSL.

If a contained bean property is creatable (for example, you can add a new server to the domain's servers collection, or you can create an RDBMSSecurityStore for the domain), then create form resources are also provided which return a template JSON object with default values to help you create the new resource. The general procedure is that you GET the create form, fill in the values, then POST it back to create the new resource. If any fields are not filled in, they retain their current values. The URLs of the create form resources are

<singlularCollectionPropertyName>CreateForm, for example:

- .../edit/serverCreateForm
- .../edit/securityConfiguration/realms/myrealm/ RDBMSSecurityStoreCreateForm

Each bean operation maps to its own URL. For example, .../domainRuntime/serverRuntimes/<serverName>/shutdown is used to shut down a specific server.

Most of the WLS bean operations are used to create, delete, list, and find contained beans. These operations are handled separately in REST (versus exposed as REST operation URLs). They are described in Using the WLS RESTful Management Interface.

2.2.6 JSON Mappings

REST maps the various Java types that the WLS beans use (for example, their properties, operation arguments and return types) to JSON.

2.2.6.1 Strings and Scalars

Java strings and scalars are mapped to their JSON equivalent.

Java	JSON	Example (Java to JSON)
java.lang.String	string or null	"Foo" -> "Foo"
		null -> null
char,	string	'a' -> "a"
java.lang.Character		
int	number	7001 -> 7001
java.lang.Integer		
long		
java.lang.Long		
float	number	1.23 -> 1.23
java.lang.Float		
double		
java.lang.Double		
boolean	boolean	true -> true
java.lang.Boolean		

2.2.6.2 Arrays

Non-null Java arrays are mapped to JSON arrays. Null Java arrays are mapped to a JSON null.

2.2.6.3 Identities

Each WLS bean is uniquely identified within its bean tree by the trailing part of its URL, after the version specifier. For example, edit/machines/Machine-0.

This identity is mapped to a JSON string array, with one string for each path segment past the root resource of the tree, for example:

```
[ "machines", "Machine-0" ]
```

2.2.6.4 WLS Bean References

Some WLS bean properties contain references to other WLS beans (versus a containment relationship). The same is true for operation arguments and return types. For example, a Server bean has a reference to a Machine bean, and a Deployment bean has a reference to an array of Target beans.

Singleton references (for example, a server's machine) map to a property whose value is the identity of the referenced bean, as well as a link, for example:

Collections of references (for example, a server's candidate machines) map to an array property where each element is an object containing the referenced bean's identity as well as a link to the bean, for example:

A null reference or null reference collection is mapped to a JSON null.

2.2.6.5 java.util.Properties

java.util.Properties holds lists of properties, for example, a CommonLogMBean LoggerSeverityProperties property. It is mapped to a JSON object, with a matching string property for each property in the set of properties, for example:

```
{
    "property1": "value1",
    "property2": "value2"
}
```

Null java.util.Properties are mapped to a JSON null.

2.2.6.6 Encrypted Properties

Some WLS bean string properties are encrypted because they hold sensitive data like passwords. While clients must be able to set passwords (this is done by passing them in as cleartext strings), other users are not allowed to view them but they might want to know whether the password has a value (versus null, is not set).

The mapping is different for inbound versus outbound encrypted properties.

For outbound encrypted properties, if the password is null, it is mapped to a JSON null. If not, then it is mapped to the JSON string @Oracle_Confidential_Property_Set_V1.1#.

For inbound encrypted properties, you would typically perform a GET to get the current value of a resource, set the values for the properties that should be changed,

leaving the others with their current values, then POST the new value back. Therefore, if the value in the POST is @Oracle_Confidential_Property_Set_V1.1#, then the property is not changed (it retains the old property value). Otherwise, the value is changed to the cleartext string value in the POST.

2.3 Standard REST Responses

The REST resources return these standard HTTP response codes:

200 OK

A REST method returns 200 (OK) if the operation succeeds and does not create a new entity, for example, GET a resource, POST to invoke an operation or modify an entity, DELETE to remove an entity.

201 Created

A REST method returns 201 (CREATED) if the operation successfully created a new entity. It also returns a Location header with a link to the new entity.

202 Accepted

A REST method returns 202 (ACCEPTED) if the operation successfully initiated some asynchronous work. It also returns a Location header with a link to a resource that you can poll to find out the status of the job.

400 Bad Request

A REST method returns 400 (BAD REQUEST) if the request failed because something is wrong in the specified request, for example, invalid argument values.

401 Unauthorized

A REST method returns 401 (UNAUTHORIZED) if the user does not have permission to perform the operation. 401 is also returned if the user supplied incorrect credentials (for example, a bad password).

403 Forbidden

A REST method returns 403 (FORBIDDEN) if the user is not in the ADMIN, OPERATOR, DEPLOYER or MONITOR role.

404 Not Found

A REST method returns 404 (NOT FOUND) if the requested URL does not refer to an existing entity.

405 Method Not Allowed

A REST method returns 405 (METHOD NOT ALLOWED) if the resource exists but does not support the HTTP method, for example, if the user tries to create a server by using a resource in the domain configuration tree (only the edit tree allows configuration editing).

406 Not Acceptable

The resource identified by this request is not capable of generating a representation corresponding to one of the media types in the Accept header of the request. For example, the client's Accept header asks for XML but the resource can only return JSON.

500 Internal Server Error

A REST method returns 500 (INTERNAL SERVER ERROR) if an error occurred that is not caused by something wrong in the request. Since the REST layer generally

treats exceptions thrown by the MBeans as BAD REQUEST, 500 is generally used for reporting unexpected exceptions that occur in the REST layer. These responses do not include the text of the error or a stack trace, however, generally they are logged in the server log.

503 Service Unavailable

The server is currently unable to handle the request due to temporary overloading or maintenance of the server. The WLS REST web application is not currently running.

2.3.1 Returning Error Messages

Resources use the following formats for returning error messages.

Error Messages with One Error String

If a resource returns one error string, it uses this format:

```
HTTP/1.1 400 Bad Request
{
   type: "http://oracle/TBD/WlsRestMessageSchema",
   title: "FAILURE",
   detail: "Bean already exists:
   \"weblogic.management.configuration.ServerMBeanImpl@31fa1656([mydomain]/
Servers[Server-1])\"",
   status: 400
}
```

Error Messages with More Than One Error String

If a resource returns more than one error string, it uses this format:

```
HTTP/1.1 400 Bad Request
{
    type: "http://oracle/TBD/WlsRestMessagesSchema",
    title: "ERRORS",
    status: 400,
    wls:errorsDetails: [
        {
            type: "http://oracle/TBD/WlsRestMessageSchema",
            title: "FAILURE",
            detail: "no-such-protocol is not a legal value for DefaultProtocol.\
            The value must be one of the following: [t3, t3s, http, https, iiop, iiops]",
            o:errorPat: "defaultProtocol"
        },
        {
            type: "http://oracle/TBD/WlsRestMessageSchema",
            title: "FAILURE",
            detail: "Type mismatch. Cannot convert abc to int",
            o:errorPath: "listenPort"
        }
    }
}
```

Using the WLS RESTful Management Interface

This chapter describes how to use the RESTful management services supported by WebLogic Server. For example scripts that show how to use the WLS REST APIs to perform common domain and partition management and monitoring tasks, see Domain Level REST API Examples and Partition Specific REST API Examples.

Topics

- Accessing REST Resources
- Viewing WLS Beans
- Viewing Collections of Contains Beans
- **Retrieving Create Forms**
- Filtering Results
- Modifying the WLS Configuration
- Using Multiple Edit Sessions
- Creating WLS Configuration Beans
- Managing Whether a Property Is Set
- **Invoking Operations**
- **Using Queries**
- About Synchronous and Asynchronous Operations
- Deploying Applications and Libraries

3.1 Accessing REST Resources

Each REST resource method documents which user roles can access it: Admin, Deployer, Operator, Monitor.

In general:

- You must be in the Admin, Deployer, Operator or Monitor role to read resources (use the GET method).
- You must be in the Admin role to write resources (use the POST and DELETE methods) or to invoke operations (using POST).

• However, with certain resources, a Deployer can deploy and undeploy applications and libraries, and an Operator can start a server.

If the user is a domain user (for example, defined in the domain's default security realm), the URL to access REST resources starts with http://host:port/management. If the user is a partition user (for example, defined in that partition's security realm), the URL to access REST resources starts with http://host:port/partition_name/management.

For more information about user roles in WebLogic Server Multitenant, see "Administrative Roles for Configuration and Management" in *Using WebLogic Server Multitenant*.

3.2 Viewing WLS Beans

To view a WLS bean, invoke the HTTP GET method on its corresponding REST URL. For example, to get the configuration for the server, Server-0:

```
GET http://localhost:7001/management/weblogic/latest/edit/latest/servers/Server-0
```

GET returns a standard WLS REST response body. It returns a JSON object containing the bean's properties and a links property, a JSON array containing links to related resources.

3.2.1 About WLS Bean Properties

The returned JSON object contains the WLS bean's properties (for example, typical properties and references, but not children), using the standard Java to JSON mappings (see JSON Mappings). It also includes an identity property that specifies the bean's identity. For example:

```
{
  identity: [ "domain", "servers", "Server-0" ],
  name: 'Server-0',
  listenPort: 7001,
  machine: { identity: [ "domain", "machines", "Machine-0" ] }
}
```

3.2.2 Self and Canonical Links

All resources include a self and a canonical top level link that refer to the resource. For example, a server contains self and canonical links that refer to the specified server:

The cross-references of these links refer to that REST resource also, therefore, include the name of the tree in which the resource is a child, for example, edit, domainRuntime, serverConfiguration, and such.

3.2.3 Parent Links

All resources, except for root resources, include a top level link to their parent resource. The link's rel property is set to parent.

Collection children return links to the collection resource, for example, a server returns a link to the server's collection resource:

Similarly, singleton children return links to their parent resource, for example, an SSL bean returns a link to the server bean:

3.2.4 Self Create Form Links

If a bean is a creatable, optional singleton (for example, a realm's RDBMSSecurityStore), and the bean currently does not exist, then a link to its corresponding create form resource is also returned. The link's rel property is set to create. For example, calling GET on a security realm's adjudicator also returns:

3.2.5 Child Bean Links

Since a WLS bean's containment properties (for example, children) are mapped to separate REST resources, they are returned as top level links in the JSON response body.

Each link's rel property is mapped to the bean property's name. For example, calling GET on Server-0 returns:

```
links: [
  // mandatory singleton child:
  {
   rel: "SSL",
    href: "http://localhost:7001/management/weblogic/latest/servers/Server-0/SSL"
  },
  // writable collection of children:
  {
```

```
rel: "networkAccessPoints",
    href: "http://localhost:7001/management/weblogic/latest/edit/servers/Server-0/
networkAccessPoints"
    }
]
```

3.2.6 Child Create Form Links

Links to create form resources are returned for creatable containment properties (singletons and collections). The link's rel property is set to <singularPropertyName>CreateForm. For example, calling GET on Server-0 also returns:

3.2.7 Singleton Bean Reference Links

WLS beans return top level links for each non-null singleton reference. The link's rel property is set to the name of the reference property. For example, if Server-0 refers to Machine-0:

If Server-0 has no machine reference:

```
{
    machine: null
}
```

3.2.8 Bean Reference Collection Links

WLS beans return nested links for each reference in a reference collection. The link's rel property is set to self.

For example, if Application-0 refers to the targets Server-0 and Cluster-0:

```
identity: ["servers", "Server-0"],
     links: [ { rel: "self", href: "http://localhost:7001/management/weblogic/
latest/edit/servers/Server-0" } ]
```

3.2.9 Operation Links

Resources also return top level links to their operation resources. The links' rel properties are set to action and the links' titles are set to the name of the operation. For example, a ServerRuntimeMBean returns:

```
links: [
     rel: "action",
     title: "suspend",
     href: "http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/suspend"
     rel: "action",
     title: "resume",
     href: "http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/resume"
     rel: "action",
     title: "shutdown",
     href: "http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/shutdown"
  ]
}
```

3.3 Viewing Collections of Contains Beans

To view a collection of WLS beans, invoke the HTTP GET method on its corresponding REST URL. For example, to get the configuration of all the servers:

```
GET http://localhost:7001/management/weblogic/latest/edit/servers
```

GET returns a standard WLS REST response body. items contains the children's properties. Each item has embedded self and canonical links to that child's resource.

Only the immediate children are returned. For example, if you get the servers collection, each server's properties will be returned, but the server's children (such as SSL) are not returned.

3.3.1 About Collection items

The resource returns a JSON object for each child in the collection. These objects contain the same data as the items returned from calling GET on the children's resources. For example, getting the domain bean's servers collection returns:

```
items: [
  { name: "Server-1", listenPort: 7001, ... },
  { name: "Server-2", listenPort: 7003, ... }
```

}

3.3.2 About Collection Links

A collection resource returns the following links:

- self and canonical links to itself.
- A link to its parent.
- A link to its corresponding create form resource if the collection is writable.
- Nested self and canonical links to each of its children.

For example, getting the domain bean's servers collection returns:

```
items: [
    {
     name: "Server-1",
     listenPort: 7001,
     links: [
       { rel: "self", href: "http://localhost:7001/management/weblogic/latest/edit/
servers/Server-1" }
      { rel: "canonical", href: "http://localhost:7001/management/weblogic/latest/
edit/servers/Server-1" }
     ]
     name: "Server-2",
     listenPort: 7005,
     links: [
      { rel: "self", href: "http://localhost:7001/management/weblogic/latest/edit/
servers/Server-1" }
      { rel: "canonical", href: "http://localhost:7001/management/weblogic/latest/
edit/servers/Server-1" }
     ]
  ]
    { rel: "self", href: "http://localhost:7001/management/weblogic/latest/edit/
servers" }
   { rel: "canonical", href: "http://localhost:7001/management/weblogic/latest/edit/
servers" }
    { rel: "parent", href: "http://localhost:7001/management/weblogic/latest/edit" }
    { rel: "create-form", href: "http://localhost:7001/management/weblogic/latest/
edit/serverCreateForm" }
  ]
```

3.4 Retrieving Create Forms

To retrieve a create form for creating a new resource, invoke the HTTP GET method on its corresponding create form REST URL. For example, to retrieve a create form for creating a new server:

GET http://localhost:7001/management/weblogic/latest/edit/serverCreateForm

GET returns a standard WLS REST response body. It returns a JSON object containing the create form's properties and a links property which is a JSON array containing links to related resources.

3.4.1 About Create Form Properties

The returned JSON object contains a property for each writable property (normal properties and references) that may be specified when creating a new resource of that type. The property's value will either be the default value from the type's bean info (if available), or the default value for the property's type (for example, 0 for an int). The values for reference properties are always null. For example, getting the domain's serverCreateForm returns:

```
{
  name: null, // identity - unique names are not generated
  idleConnectionTimeout: 65, // from the default value in the bean info
  replicationGroup: null, // default value for a String since the bean info does not
provide a default value
  machine: null, // singleton reference
  candidateMachines: null, // reference collection
  ...
}
```

3.4.2 About Create Form Links

A create form returns the following links:

- self and canonical links to itself.
- A link to its parent.
- A create link to the corresponding resource that can be used to create a resource of this type.

For example, getting the domain bean's serverCreateForm returns:

3.5 Filtering Results

Bean, collection, and create form resource GET methods support the following query parameters to let you omit properties and links from the response:

Parameter Name	Description	
fields	Only return these properties.	
excludeFields	Return all properties except for these properties.	

Parameter Name	Description	
links	Only return links with these rel names.	
excludeLinks	Return all links except for the ones with these rel names.	

fields and excludeFields are mutually exclusive, as are links and excludeLinks. All the values are comma-separated lists of names.

For example, to only retrieve a server's self and parent links, and name and listenPort properties:

3.6 Modifying the WLS Configuration

You can create, modify and delete beans in the edit tree *only* (.../management/weblogic/<version>/edit/...). The other bean trees are read-only.

All WLS bean edits must be performed within a configuration transaction:

- If you already have started a transaction, the REST changes will be made in the same transaction. You will still be responsible for committing or rolling back the transaction.
- If you have not started a transaction, the REST resource will begin a transaction on your behalf, try to make the changes, and either commit or roll back the transaction depending on whether the changes could be made (auto-transactions).
- If someone else already has started a transaction, the REST resource will return an error (instead of modifying the configuration).

Sometimes a configuration transaction cannot be committed unless complementary changes to multiple beans are made in the same transaction. In these cases, you need to begin and end the transaction explicitly versus relying on auto-transactions.

Also, when the client manages the transaction, each REST call saves the changes (but does not activate them). There is some MBean validation that occurs during the save operation which might cause it to fail. For example, when you create a JDBC system resource, the changes cannot be saved until after its child JDBC resource name is set. For cases like this, use the saveChanges=false query parameter.

For more information, see the changeManager resources in *RESTful Edit Reference for Oracle WebLogic Server*.

3.6.1 Modifying WLS Configuration Beans

To modify a WLS bean, construct a JSON object containing the values you want to change then invoke the HTTP POST method on its corresponding REST URL, passing in that JSON object as the request body.

For example, to change a server's listen port and administration port:

```
curl ... -d "{
   listenPort: 7007,
   administrationPort: 9007
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers/Server-0
```

This is similar to an HTTP PATCH operation where you only modify part of the bean, versus needing to pass in all of the bean's properties every time.

3.6.2 About the JSON Object Request Body

You construct a JSON object containing the values you want to change. Some WLS bean properties are read-only (for example, a server's name). Read-only properties are ignored.

You don't have to pass in all of the bean's properties. Any properties not passed in will retain their current values. As was described in Encrypted Properties, GET returns the value @Oracle_Confidential_Property_Set_V1.1# for an encrypted string property that has a non-null value. If you POST back this value, then the property will retain its current value. If you want to change the encrypted property's value, then set the value to the cleartext string that you want it to be, for example:

```
{ defaultIIOPPassword: "admin123" }
```

To change a reference, pass in its identity. The same is true for reference collections. This replaces the reference collection versus adding references to the collection. For example, to set a server's machine to Machine-0 and candidate Machines to Machine-0 and Machine-1:

Also, use null to remove references. For example, to remove a server's machine and candidate machines' references:

```
{
  machine: null,
  candidateMachines: null
}
```

If you pass in a mixture of valid and invalid values, the valid ones are written and errors are returned for the invalid ones, and overall, the REST method returns an OK status code. For example:

```
curl ... -d "{
   listenPort: 7007,
   administrationPort: 'foo'
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers/Server-0
```

```
HTTP/1.1 200 OK
{
   messages: [
      {
       severity: "FAILURE",
       field: "administrationPort",
       message: "Something about the value needs to be an integer"
   }
   ]
}
```

In this example, the listen port is modified and the administration port is not. The method returned an OK status code.

3.7 Using Multiple Edit Sessions

In a previous release, WLS introduced multiple edit sessions. (See "Managing Named Concurrent Edit Sessions" in *Using WebLogic Server Multitenant*.) These edit sessions are scoped. There is one scope for domain level edit sessions and one per partition. Each scope has a default edit session. Edit session names are unique within a scope, but not across scopes.

For all the REST resources in the edit tree, you must specify which edit session to use —the name of the scope and the name of the edit session within that scope.

The edit session scope name is derived from the URL. If you use a non-partitioned REST URL, then REST uses the domain level scope. If you use a partitioned REST URL, then REST uses that partition's scope.

Within that scope, REST must know which edit session to use. You can either specify a header which states exactly which edit session to use, or you can let REST use defaulting rules to pick one.

3.7.1 Client Specified Edit Session

You can select the edit session by including a weblogic.edit.session header in the request. The header's value is used as the edit session name. For example:

```
\verb|curl ... -H weblogic.edit.session=MySession ... \\
```

Each edit session scope has a default edit session named default. To explicitly select the scope's default edit session:

```
\verb|curl ... -H weblogic.edit.session=default ... |
```

3.7.2 The Default Edit Session

If you did not include the weblogic.edit.session header, the REST resources use the following rules to select an edit session:

- If you currently have one edit session locked in the scope, REST will use it.
- Or, if you have created one edit session in the scope, REST will use it.
- Otherwise, REST will use the scope's default edit session.

3.8 Creating WLS Configuration Beans

You create a new WLS configuration bean by calling POST with a JSON structure containing the new bean's properties. To make this easier, you can use the corresponding create form resource to retrieve a template JSON structure that is populated with default values for the various writeable properties.

3.8.1 URLs For Creating WLS Configuration Beans

To create a collection child, call POST on the collection's URL, for example, http://localhost:7001/management/weblogic/latest/edit/servers.

To create an optional singleton child, call POST on the proposed child's URL, for example, http://localhost:7001/management/weblogic/latest/edit/securityConfiguration/realms/myRealm/adjudicator.

To retrieve a create form, call GET on the corresponding create form resource, for example:

http://localhost:7001/management/weblogic/latest/edit/serverCreateForm

And

 $\label{localhost:7001/management/weblogic/latest/edit/securityConfiguration/realms/myRealm/adjudicatorCreateForm$

3.8.2 Getting a JSON Template

The underlying WLS beans have default values for many properties. You typically want to display these default values and perhaps, customize them, then use them to create a new WLS bean. You can get these default values by calling GET on the corresponding create form resource. For example:

```
curl ... -X GET http://localhost:7001/management/weblogic/latest/edit/
serverCreateForm
HTTP/1.1 200 OK
{
    listenPort: 7001,
    ...
}
```

3.8.3 Creating the Bean

To create the WLS configuration bean, call POST on a JSON object containing the new bean's properties.

The JSON object does not need to include all the possible properties. Unspecified properties are set to their default values. All collection children need to be assigned a unique identity within their collection, for example, a server needs a unique name. Therefore, the identity property is not optional.

The response contains a location header containing the resource's URL. For example:

```
curl ... -d "{
  name: "Server-1",
  defaultProtocol: "t3s"
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers
HTTP/1.1 201 Created
```

If a bean with that name already exists, the resource returns a BAD_REQUEST status code along with a failure message. For example:

```
curl ... -d "{
  name: "Server-1"
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers
HTTP/1.1 400 Bad Request
{
  type: "http://oracle/TBD/WlsRestMessageSchema",
  title: "FAILURE",
  detail: "Bean already exists:
  \"weblogic.management.configuration.ServerMBeanImpl@31fa1656([mydomain]/
Servers[Server-1])\"",
  status: 400
}
```

Similar to updating a WLS configuration bean, you can pass in a mixture of valid and invalid values. Read-only properties and properties that the bean does not support are ignored. If there is an exception setting a property, the resource adds a failure message to the response. After processing all of the properties, if there were any errors, the resource attempts to delete the new bean and returns a BAD_REQUEST status code.

Example 3-1 Mixture of valid and invalid properties

```
curl ... -d "{
  name: "Server-1",
  listenPort: abc,
  defaultProtocol: "no-such-protocol",
  adminstrationProtocol: "iiop"
" -X POST http://localhost:7001/management/weblogic/latest/edit/servers
HTTP/1.1 400 Bad Request
  type: "http://oracle/TBD/WlsRestMessagesSchema",
  title: "ERRORS",
  status: 400,
  wls:errorsDetails: [
      type: "http://oracle/TBD/WlsRestMessageSchema",
     title: "FAILURE",
      detail: "no-such-protocol is not a legal value for DefaultProtocol.\
     The value must be one of the following: [t3, t3s, http, https, iiop, iiops]",
      o:errorPat: "defaultProtocol"
      type: "http://oracle/TBD/WlsRestMessageSchema",
      title: "FAILURE",
      detail: "Type mismatch. Cannot convert abc to int",
      o:errorPath: "listenPort"
```

```
]
}
}
```

Example 3-2 All valid properties

```
curl ... -d "{
  name: "Server-1",
  listenPort: 7003,
  defaultProtocol: "https",
   adminstrationProtocol: "iiop"
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers
HTTP/1.1 201 Created
Location: http://localhost:7001/management/weblogic/latest/edit/servers/Server-1
```

3.8.4 Deleting WLS Configuration Beans

To delete a WLS bean (both collection children and optional singleton children), invoke the HTTP DELETE operation on its corresponding REST URL. Any references to that bean will be removed also. For example, to delete a server:

3.9 Managing Whether a Property Is Set

An MBean property can either be set or unset. If it is set, its value is persisted (for example, to config.xml) and locked in. If it is unset, then a default value is used. The value can either be the default value for the property's type, a hard coded default value, or a computed default value that runs some custom Java code.

By default, when you call GET on a resource, it returns the property's current value. When you set the value of a String property to null or an empty string, it unsets the property (returns it to its default value).

REST lets you determine whether a property has been set, and explicitly set or unset a property.

If you set the expandedValues query parameter to true when getting a resource, each value is returned as a JSON object with a set Boolean property and a value property that holds the current value. For example, getting a server returns:

```
curl ... -X GET \
  http://localhost:7001/management/weblogic/latest/edit/servers/myserver?
&expandedValues=true
{
  listenPortEnabled: { set: false, value: true }, // currently not set
  name: { set: true, value: "myserver" }, // currently set
  listenPort: { set: true, value: 7003 } // currently set
}
```

Similarly, you can use the expandedValues query parameter to explicitly set or unset values. For example, to unset the listen port and set the listen address to an empty string:

```
curl ... -d "{
  listenPort: { set: false }, // value will be ignored if specified
  listenAddress: { set: true, value: "" }
}" -X POST http://localhost:7001/management/weblogic/latest/edit/servers/myserver?
expandedValues=true
```

3.10 Invoking Operations

Each WLS bean operation maps to its own REST URL. In the case of overloaded operations (for example, shutdown() versus shutdown(int, boolean)), all the overloaded operations map to the same URL and the resource looks at the incoming arguments to determine which operation to invoke.

If the operation requires input arguments, they are specified by passing in a JSON object request body with a property for each argument. The name of the property matches the name of the argument.

If the operation does not take input arguments, you must pass in a JSON object with no properties.

Similarly, if the operation returns a value, then it is returned in a standard REST response body's JSON object return property. If the operation is void, the response body does not include an return property.

If the underlying MBean operation throws an exception, the REST method returns a BAD REQUEST (404) response containing the exception's text.

Example 3-3 void operation with no arguments : void shutdown()

```
curl ... -d "{}" \
-X POST http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/shutdown
{
    // response does not include a 'return' property since it's a void operation
}
```

Example 3-4 void operation with multiple arguments : void shutdown(int timeout, boolean ignoreSessions)

```
curl ... -d "{ timeout: 500, ignoreSessions: false }" \
-X POST http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/shutdown
{
    // response does not include a 'return' property since it's a void operation
}
```

Example 3-5 non-void operation with an argument: String getURL(String protocol)

```
curl ... -d "{ protocol: 'http' }" \
-X POST http://localhost:7001/management/weblogic/latest/domainRuntime/
serverRuntimes/Server-0/getURL
{
   return: "http://localhost:7003"
}
```

3.11 Using Queries

The REST API includes a powerful bulk access capability that lets you dynamically describe a tree of beans that can be returned in one call. Each tree (for example, edit, domain runtime, and such), has a root search resource. You can POST a query to these search resources. The query indicates which beans (and properties and links) should be returned, and, as such, returns a portion ("slice") of the bean tree.

Bulk access can only be used for reading; it cannot be used for writing.

3.11.1 Search Resources

Each bean tree includes a search resource for bulk queries.

On the Administration Server:

URL	Description
/management/edit/search	Returns a slice of the edit bean tree (in progress edits that have not been saved to disk yet).
/management/domainConfig/ search	Returns a slice of the last configuration bean tree that was saved to disk (versus the configuration the servers are currently using).
/management/domainRuntime/ search	Returns a slice of the Administration Server's domain runtime bean tree (which covers all the servers' runtime bean trees).
/management/serverConfig/ search	Returns a slice of the Administration Server's configuration bean tree (the configuration the Administration Server is running against).
/management/serverRuntime/ search	Returns a slice of the Administration Server's runtime bean tree.

On Managed Servers:

URL	Description
/management/serverConfig/ search	Returns a slice of Managed Server's configuration bean tree (the configuration the server is running against).
/management/serverRuntime/ search	Returns a slice of the Managed Server's runtime bean tree.

When you POST a query to a search resource, the query starts searching at the root bean of the tree. The resource returns a JSON response containing the results of the query, that "slice" of the bean tree.

3.11.2 Object Queries

An object query describes what data should be returned for a WLS bean (or collection of beans), such as:

- Which of the bean's properties should be returned.
- Which of the bean's links should be returned.
- Which of the bean's children should be returned.
- For a collection, which of its children should be returned.

Note that all searches start at the root bean of the search resource's tree. For example, if you POST a query to management/domain/runtime, it starts searching at the DomainRuntimeMBean in the domain runtime tree.

3.11.2.1 Fields and ExcludeFields

fields specifies which bean properties (for example, scalars and references) are returned. It is a JSON string array of property names. For example, to return the domain's name and configurationVersion:

```
curl ... -d "{ fields: [ 'name', 'configurationVersion' ] }" \
-X POST http://localhost:7001/management/weblogic/latest/edit/search
```

If the query lists properties that the bean does not support, then that part of the query is ignored (instead of returning an error). If fields is not specified, then all of the properties are returned.

excludeFields specifies a list of fields that should not be returned; all other properties are returned. fields and excludeFields are mutually exclusive.

Note that a query's fields and excludeFields properties mirror the fields and excludeFields query parameters that you can specify when calling GET on a resource. The difference is that the query parameters use comma-separated names and queries use JSON arrays of names.

3.11.2.2 Links and ExcludeLinks

links specifies which of the bean's links should be returned. It is a JSON string array of link rel names. For example, to return the domain's self and servers links:

```
curl ... -d "{ links: [ 'self', 'servers' ] }" \
-X POST http://localhost:7001/management/weblogic/latest/edit/search
```

If the query lists links that the bean does not support, then that part of the query is ignored (instead of returning an error).

If links is not specified, then all the links are returned (except for collection children, which only return their self and canonical links by default).

Similarly, excludeLinks specifies a list of links that should not be returned; all other links are returned. links and excludeLinks are mutually exclusive.

To return all of a collection's children's links, use excludeLinks: [].

Note that a query's links and excludeLinks properties mirror the links and excludeLinks query parameters that you can specify when calling GET on a resource.

3.11.2.3 Children

children specifies which child bean properties are returned. It is a JSON object whose property names are the names of the children to return, and whose values are object queries. For example, to get the domain's name, along with the name and listen port of each server:

```
curl ... -d "{
  fields: [ 'name' ], // only return the domain's name
  children: {
    servers: { // fetch the domain's 'servers' collection
        fields: [ 'name', 'listenPort' ] // only return each server's name and listen
port
    }
  }
} " -X POST http://localhost:7001/management/weblogic/latest/edit/search
```

If children is not specified, then none of the bean's children are returned.

3.11.2.4 Identities

Sometimes you want to only return certain items in a collection (for example, myserver and Server-0). Each collection child has a property that specifies its identity. Typically this is the name property. The query uses this property name to specify which children of a collection are returned. It is a JSON string array of identities. fields and links can also be used to control which properties and links are returned for each of these children. For example, to return the name and listen port for the servers, Server-0 and Server-1:

```
curl ... -d "{
  fields: [ 'name' ], // only return the domain's name
  children: {
    servers: { // fetch the domain's 'servers' collection
        names: [ 'Server-0', 'Server-1' ], // only return the children whose 'name' is
'Server-0' or 'Server-1'
        fields: [ 'name', 'listenPort' ] // only return each server's name and listen
port
    }
}" -X POST http://localhost:7001/management/weblogic/latest/edit/search
```

Identities that do not exist are ignored (instead of returning an error). Similarly, if the context is not a collection, then this part of the query is ignored. By default, all collection children are returned.

3.11.3 Response Body

The response body follows the usual pattern (inline properties or items, depending on whether the URL is for a bean or a collection). The child beans are returned as nested properties. For example:

```
curl ... -d "{
 fields: [], // don't return any domain level properties
 links: [], // don't return any domain level links
 children: {
    servers: { // fetch the domain's 'servers' collection
      names: [ 'Server-0', 'Server-1' ], // only return the children whose 'name' is
'Server-0' or 'Server-1'
      fields: [ 'name' ], // only return each server's name
      links: [], // don't return any per-server links
      children: {
        SSL: {
          \verb|fields: [ 'listenPort' ], // only return each server's SSL listen port|\\
          links: [] // don't return any SSL level links
" -X POST http://localhost:7001/management/weblogic/latest/edit/search
{code:JavaScript}
HTTP/1.1 200 OK
 servers: {
    items: [
       name: "myserver",
        SSL: { listenPort: 7002}
```

```
},
    {
        name: "AnotherServer",
        SSL: { listenPort: 7002}
      }
      ]
    }
}
```

3.11.4 Query Examples

This example gets the component runtimes of specific applications on all running servers. It only returns the name for the server runtimes and application runtime parents and returns all of the component runtimes' properties.

This example gets all of the servlet runtime and EJB runtime information for a set of applications across all running servers.

```
curl ... -d "{
 links: [],
 fields: [],
 children: {
    serverRuntimes: {
     links: [],
     fields: [ 'name', 'state' ],
     children: {
        applicationRuntimes: {
         name: [ 'myapp', 'BasicApp' ],
          links: [],
          fields: [ 'name', 'healthState' ],
          children: {
            componentRuntimes: {
              links: [],
              fields:[
                'name',
                'healthState',
                'contextRoot',
                'openSessionsCurrentCount',
                'sessionsOpenedTotalCount'
              ],
```

```
children: {
  EJBRuntimes: {
   links: [],
    fields: [
      'EJBName',
      'type'
    ],
   children: {
      transactionRuntime: {
        links: [],
       fields: [
          'transactionsCommittedTotalCount',
          'transactionsRolledBackTotalCount',
          'transactionsTimedOutTotalCount'
       1
      },
      poolRuntime: {
       links: [],
       fields: [
          'accessTotalCount',
          'missTotalCount',
          'destroyedTotalCount',
          'pooledBeansCurrentCount',
          'beansInUseCurrentCount',
          'waiterCurrentCount',
          'timeoutTotalCount'
       ]
      },
      cacheRuntime: {
       links: [],
        fields: [
          'cachedBeansCurrentCount',
          'cacheAccessCount',
          'cacheMissCount',
          'activationCount',
          'passivationCount'
        ]
      },
      lockingRuntime: {
       links: [],
        fields: [
          'lockEntriesCurrentCount',
          'lockManagerAccessCount',
          'waiterTotalCount',
          'waiterCurrentCount',
          'timeoutTotalCount'
        ]
      },
      timerRuntime: {
       links: [],
        fields: [
          'timeoutCount',
          'cancelledTimerCount',
          'activeTimerCount',
          'disabledTimerCount'
  },
 servlets: {
   links: [],
```

3.12 About Synchronous and Asynchronous Operations

Several MBean operations (for example, server lifecycle, deployment) are asynchronous. They return job MBeans that must be monitored to determine when the job has completed.

Asynchronous MBean operations return a 200 OK, 201 Created or 400 Bad Request if the operation completed or failed immediately. Otherwise, they return a 202 Accepted and you must poll the returned job resource to find out when the work is done. By default, REST makes a best effort attempt to wait for the work to complete, but returns after about 5 minutes. You can specify the Prefer header to control how long REST waits for the work to complete.

Table 3-1 describes using the Prefer header.

Table 3-1 Using the Prefer Header

Header	Description
-X Prefer:respond-async	The client polls a returned job resource. REST returns a 200 OK, 201 Created, or 400 Bad Request if the asynchronous MBean operation finishes immediately; otherwise it returns a 202 Accepted.
-X Prefer:wait=# For example, -X Prefer:wait=10	The REST resource internally polls the job for up to the specified number of seconds and returns a 200 OK, 201 Created, or 400 Bad Request if the asynchronous MBean operation finishes within that time; otherwise it returns a 202 Accepted, along with a Location header containing the URL of a REST task resource that the client can poll (via GET) to find out when the work is done.

If you don't specify the Prefer header, REST will return a 200 OK, 201 Created, or 400 Bad Request if the asynchronous MBean operation finishes within approximately 5 minutes, otherwise it returns a 202 Accepted.

If you specify both respond-async and wait, respond-async is ignored.

For examples of synchronous and asynchronous operations, see Domain Level REST API Examples and Partition Specific REST API Examples.

3.13 Deploying Applications and Libraries

You view deployed applications and libraries in the edit tree. You call POST on the collections to deploy them, and DELETE to undeploy them. Similarly, the deployment MBeans take server relative pathnames. In addition, you can upload files from the client to the server then deploy them and use create form resources to inspect deployments (for example, to determine their preferred name and version numbers). For examples of deploying domain-scoped and partition-scoped applications, see Domain Level REST API Examples and Partition Specific REST API Examples.

Domain Level REST API Examples

This chapter contains example scripts for users in domain level roles using WebLogic Server REST APIs to perform common domain and partition management and monitoring tasks. For more information, see Accessing REST Resources.

Topics

- Adding Users
- Setting Up Servers
- Creating Partitions
- Configuring System Resources
- Deploying Domain-Scoped Applications
- Monitoring Domain Resources
- Starting and Stopping Domain-Scoped Applications
- Starting and Stopping Partitions
- Starting and Stopping Servers

4.1 Adding Users

The following example script demonstrates how a System Administrator adds users such as Operators, Deployers, and Monitors.

Note: To view long URLs, use the scroll bar located beneath the section. Demonstrate a domain admin configuring domain level users Create a deployer curl -v \ --user admin:admin123 \

```
-H X-Requested-By:MyClient \
-H Accept:application/json \
-H Content-Type:application/json \
-d "{
    userName: 'deployer',
     password: 'deployer123',
     description: 'A domain level deployer'
-X POST http://localhost:7001/management/weblogic/latest/serverConfig/
securityConfiguration/realms/myrealm/authenticationProviders/DefaultAuthenticator/
createUser

addMemberToGroup

HTTP/1.1 200 OK
Response Body:
{}
```

4.2 Setting Up Servers

The following example script demonstrates how a System Administrator creates a cluster, machine, and dynamic server targeted to the cluster, including setting up resource management for the Managed Servers. For more information about resource management, see "Configuring Resource Consumption Management" in *Using WebLogic Server Multitenant*.

Note:

To view long URLs, use the scroll bar located beneath the section.

```
--user admin:admin123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \

4.3 Creating Partitions

The following example script demonstrates how a System Administrator creates a partition, including:

- A new security realm for the partition, including security providers, the primary identity domain, and the management identity domain
- A virtual target for the cluster, on which the applications will run
- A virtual target for the Administration Server, so that the Deployer can create system resources and deploy applications
- · A resource group for each virtual target
- Partition users in the Administrator, Deployer, Monitor, and Operator roles
- Creating a resource manager for the new partition to monitor and control system resource sharing by collocated partition users

Note:

To view long URLs, use the scroll bar located beneath the section.

```

4.4 Configuring System Resources

The following example script demonstrates how a Deployer configures JDBC and JMS system resources.

Note:

To view long URLs, use the scroll bar located beneath the section.

```
Demonstrate a domain deployer configuring system resources
View the default values for a new global JDBC system resource
______
curl -v \

```

4.6 Monitoring Domain Resources

The following example script demonstrates how an Operator monitors the entire domain, including its partitions and resource managers. Resource managers monitor and control system resource sharing by collocated partition users. For more information about resource management, see "Configuring Resource Consumption Management" in *Using WebLogic Server Multitenant*.

The example script also shows how to monitor data sources and JMS.

Note:

To view long URLs, use the scroll bar located beneath the section.

Demonstrate a domain monitor monitoring the domain

```
Monitor the servers
curl -v \
--user monitor:monitor123 \
-H X-Requested-By:MyClient \

4.8 Starting and Stopping Partitions

The following example script demonstrates how an Operator starts and stops partitions.

Note:

To view long URLs, use the scroll bar located beneath the section.

Demonstrate a domain operator starting and stopping a partition

```
View the partition's state
curl -v \
--user operator:operator123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \
-X GET http://localhost:7001/management/weblogic/latest/domainRuntime/
domainPartitionRuntimes/Partition1/partitionLifeCycleRuntime?
links=none&fields=name, state
HTTP/1.1 200 OK
Response Body:
    "name": "Partition1",
    "state": "RUNNING"
Synchronously gracefully shut down the partition
curl -v \
--user operator:operator123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \
-H Content-Type:application/json \
-d "{
  timeout: 10, ignoreSessions: true
-X POST http://localhost:7001/management/weblogic/latest/domainRuntime/
domainPartitionRuntimes/Partition1/partitionLifeCycleRuntime/shutdown
HTTP/1.1 200 OK
Response Body:
    "links": [{
        "rel": "job",
        "href": "http:\/\/localhost:7001\/management\/webloqic\/latest\/domainRuntime

4.9 Starting and Stopping Servers

The following example script demonstrates how an Operator starts and stops servers.

Note:

To view long URLs, use the scroll bar located beneath the section.

```
Demonstrate a domain operator starting and stopping servers
View the servers' states
curl -v \
--user operator:operator123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \
-X GET http://localhost:7001/management/weblogic/latest/domainRuntime/
serverLifeCycleRuntimes?links=none&fields=name,state
HTTP/1.1 200 OK
Response Body:
{"items": [
        "name": "Cluster1Server1",
        "state": "RUNNING"
        "name": "AdminServer",
        "state": "RUNNING"
        "name": "Cluster1Server2",
        "state": "RUNNING"
] }
```

```
Synchronously shutdown a server

Partition Specific REST API Examples

This chapter contains example scripts for users in partition level roles using WebLogic Server REST APIs to perform common partition management and monitoring tasks. For more information, see Accessing REST Resources.

Topics

- Configuring Users
- Creating Partition-Scoped System Resources
- Deploying Partition-Scoped Applications
- Monitoring Partition Resources
- Starting and Stopping Partition-Scoped Applications

5.1 Configuring Users

The following example script demonstrates how a Partition Administrator configures users such as Operators, Deployers, and Monitors, for a new partition.

Note:

To view long URLs, use the scroll bar located beneath the section.

```
Demonstrate a partition admin configuring a partition

Create a deployer, operator and monitor for the new partition

curl -v \
--user Partition1Admin:Partition1Admin123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \
-H Content-Type:application/json \
-d "{

userName: 'Partition1Deployer',
 password: 'Partition1Deployer123',
 description: 'Partition1 deployer'
```

5.3 Deploying Partition-Scoped Applications

The following example script demonstrates how a Deployer deploys partition-scoped applications.

Note:

To view long URLs, use the scroll bar located beneath the section.

5.4 Monitoring Partition Resources

The following example script demonstrates how a Monitor monitors the servers, partitions, applications, JMS, and data sources in a partition, including monitoring the resource manager. For more information about resource management, see "Configuring Resource Consumption Management" in *Using WebLogic Server Multitenant*.

Note:

To view long URLs, use the scroll bar located beneath the section.

```

5.5 Starting and Stopping Partition-Scoped Applications

The following example script demonstrates how an Operator starts and stops partition-scoped applications.

Note:

To view long URLs, use the scroll bar located beneath the section.

```
Demonstrate a partition operator starting and stopping a partitioned app
Get the app's state on one of the servers in the cluster
______
curl -v \
--user Partition1Operator:Partition1Operator123 \
-H X-Requested-By:MyClient \
-H Accept:application/json \
-H Content-Type:application/json \
-d "{ target='Cluster1Server1' }" \
-X POST http://localhost:7001/partitions/Partition1/management/weblogic/latest/
domainRuntime/domainPartitionRuntimes/Partition1/deploymentManager/
appDeploymentRuntimes/fairShare/getState
HTTP/1.1 200 OK
Response Body:
{"return": "STATE_ACTIVE"}
Synchronously stop the app
curl -v \
